At the beginning of the nineteenth century the population of London is given as 958,863, occupying some 136,000 houses, all drained into cesspools, which had superseded that mediæval abomination, the lay-stalls, or heaps of dung and garbage dumped in corners to be removed when convenient. The death-rate was 41 per 1000. About the year 1810 water-closets of a primitive hopper pattern first came into use. These were connected with a cesspool by a square brick drain, and as it became necessary to provide an outlet for the additional amount of water the overflow was carried into the nearest sewer or water-course in defiance of the existing law, which by 1815 had become a dead letter. On the more general adoption of water-closets it was found convenient to dispense altogether with the intervening cesspool, and to carry the house drain directly into the nearest sewer or water-course. This action was stimulated by the great increase of buildings and cesspools that took place about 1830, these latter having proved both a source of annoyance and disease. The saturated ground was contaminated by the cesspools and middens of the many generations of dwellers within the limited area, and the conditions were ripe for the distribution of any water-borne disease when an epidemic once obtained a foothold. The population in 1831 had risen to 1,424,896, and in this year cholera appeared.

Cholera Epidemics.

Dr. Spencer Thomson, writing in 1852 of the visitations of cholera, says that the first visitation in 1831 was traced back through Europe and Asia to the swampy district round the mouth of the Ganges in 1817. This visitation in 1832 carried off in London alone no less than 15,000. Speaking of the second epidemic, he says that nothing had been done in the interval, and that we were prepared to nourish and foster its mysterious germs in the fœtid and stagnant air of the city, unventilated, undrained, with water half supplied or not supplied at all, or tainted with decomposition of every kind from human excrement upwards, and he adds that such will be the case again. The same views were held by other medical men and laymen who were able to appreciate the conditions. Amongst the tidal ditches of Bermondsey in the great epidemic of 1848-49 187 deaths occurred in a population of 1000. (See Note E.) In 1847 diarrhœa, dysentery, and cholera had been more than usually fatal. In London the deaths from these causes rose from 38 in the first week of July to 188 per week in the middle of August. Typhus fever and scarlet fever were also epidemic. During the epidemic of cholera, 1848-49, the deaths in London in the six weeks from Nov. 21st, 1848, to Jan. 1st, 1849, rose from 28 to 46 per 1000. The proportion of these deaths varied with the elevation and with the area of water-supply, the Lambeth and Vauxhall Companies area having the larger proportion of cases. (See Vital Statistics, W. Farr.)

Abortive Plans.

The condition of the river becoming worse—with cesspool overflows draining into the sewers on the general adoption of water-closets—in 1834 John Martin, the eminent and imaginative painter, proposed a plan for building an embankment and collecting the outfalls of the sewers on each side of the river into intercepting sewers, to discharge in the river below London. He also prepared sketches for a suspended lighthouse on the Goodwins. This, unlike his sewerage scheme, was impracticable, for he believed the sands were but 18 ft. thick, not 80 ft. to the chalk, as they are now known to be. (See Note F.) Martin's plans formed the subject of a Royal Commission, but without result. Meanwhile the evil increased with the population. At this time public and private pumps were numerous, ground water being abundant, cool, and probably sparkling with ammonia, while some of the large water companies drew their supplies from the immediate neighbourhood between Waterloo Bridge and Battersea.

Prior to the creation of the Metropolitan Commissioners of Sewers in 1848 London was administered by no less than eight separate Commissions. The *Times*, commenting in 1855 upon the state of affairs that had existed, says that "within the metropolitan limits the local administration was carried on by no fewer than 300 different bodies, deriving powers from about 250 local Acts independent of general Acts. Such a multiplicity of often ill-informed bodies only added to the existing confusion and trouble, each one doing what seemed good in its own district independently of any difficulties it created for its neighbour." It is deplorable to contemplate the technical ignorance displayed in the early period of divided responsibility in regard to the size, shape, and varying levels of the sewers intended to connect at the district boundaries. Large sewers discharged into small ones, square ones into round ones, and egg-shaped sewers, which had the smaller end down, were connected with others reversed, with the small end up, the whole result being chaotic.

John Martin's proposal was partially adopted at the creation of the Metropolitan Board of Works in 1856. Prior to that his scheme, though neglected at the time, took hold, for in 1854 a Mr. Thomas Wickford, an engineer, further elaborated Martin's plan, carrying the northern outfall sewer to Barking Creek and the southern one to the Greenwich Marshes, with provision for chemically deodorising the sewage before discharging it into the Thames. but, like the original suggestion, nothing came of it,

The fundamental idea was revived on many occasions by engineers appointed to report on the subject, but without immediate results.

Abolition of Cesspools.

Under pressure of public opinion during the cholera epidemic of 1848–49 Parliament combined in one body the several authorities then existing, under the style of the Metropolitan Commissioners of Sewers, passing the Act on Sept. 4th, 1848. Their jurisdiction extended over a radius of 12 miles from St. Paul's, but their powers were restricted. The members of this commission were nominated by the Government. Under the control of this Board all cesspools were abolished, the official number being given as 200,000, with an estimated capacity of 5,250,000 cubic feet, incredible as it now seems with cholera present and water being drawn by the companies between Kew and Waterloo Bridge. The whole of this vast mass of filth was shot, or rather pumped, into the Thames. It was now made compulsory for each house to drain into a sewer, for which purpose a great advance was made by the introduction of pipes in place of brick drains. It was owing to the efforts of this commission to obtain information relative to the position and levels of existing sewers that we owe the large-scale Ordnance Survey.

This commission was replaced the following year by a still more energetic body, who aspired to entirely reorganise the main drainage system, but failed to agree as to the plan to be adopted. Other commissions were created in quick succession, composed of men of undoubted capacity and ability for the duties, but without any practical result. In all, between the years 1847 and 1855 no less than six commissions were appointed, who had before them no less than 116 plans, including in 1854 one costly scheme for draining London on the separate system, introduced by the General Board of Health. This was a self-appointed and apparently well-informed watch committee of citizens, but either from failing to agree amongst themselves or with the Government, or from lack of Parliamentary powers to carry out their plans, they dissolved before they had done more than make proposals and criticisms.

Foul State of the River in 1855.

Meanwhile, in 1855 the population had risen to 1,889,307 on the north side and on the south side to 696,761, making a total of 2,586,068, while the houses had increased to 329,467. The death-rate, notwithstanding the cholera epidemics, had fallen in 1851–60 to 23·7, from 24·8 in the previous decade. An article published in THE LANCET in July, 1855, when matters had reached a climax, may well be quoted as describing the condition of the Thames at this time. It says:—

> The waters of the Thames are swollen with the feculence of the myriads of living beings that dwell upon the banks, and with the waste of every manufacture that is too foul for utilisation. Wheresoever we go, whatsoever we eat or drink within the circle of London we find tainted with the Thames. ..... No one having eyes, nose, or taste, can look upon the Thames and not be convinced that its waters are year by year and day by day getting fouler and more pestilential. ..... The abominations, the corruptions we pour into the Thames are not, as some falsely say, carried away into the sea. The sea rejects the loathsome tribute, and heaves it back again with every flow. Here, in the heart of the doomed city, it accumulates and destroys.

This description is not the least exaggerated. The conditions were aggravated by the retention and consequent deposition of the sewage in the neighbourhood of its discharge, as owing to the necessarily low level of the outfalls it could only escape shortly before low tide, being dammed back at other times in the sewers. Whatever sewage escaped, before the flow checked it, was carried back up stream, and only returned again to be mixed with a still fouler volume. Thus the process was repeated. Large deposits accumulated constantly in the river and the sewers; this fermenting, gave off gases such as are seldom or never met with under present conditions. During periods of heavy rainfall the sewers filled, especially if such storms occurred during high tide. At times they were unable to withstand the pressure and burst, flooding the neighbouring district, or in low-lying places vomited back their contents through the house and street gullies, with the same results. This question of flooding has been a difficulty up to the present time, and is largely responsible for the additional sewers in course of construction.

Sewerage Scheme Carried Out.

On the formation of the Metropolitan Board of Works in 1855 (see Note F), the plans of reform as designed by the late Sir Joseph Bazalgette, their engineer, were well-nigh wrecked, like those of their predecessors, through want of sufficient Parliamentary powers to give them independent action. After long debate over details, with further reports from experts appointed by the Government, additional powers were obtained following a change of Ministry, which enabled the much-delayed sewerage scheme to be taken in hand in the late autumn of 1858, though the work was not completed until 1874. Provision was made by Sir Joseph Bazalgette for a population of 3,450,000, accumulating 108,000,000 gallons of sewage every 24 hours. Added to this, allowance was made for a rainfall of ¼ inch over the more populated area and 1/10 inch over the remaining suburban portion, the south side being very sparsely populated. Even this very limited provision amounted to 286,000,000 gallons, making a grand possible total of 394,000,000 gallons. Any excess over this had to depend upon the storm overflows provided for its removal directly into the river within the metropolitan area. It is evident, if such a provision was then found to be inadequate, how much greater must be our present requirements, with the population increased by more than one-third, and with the greater part of the open land now covered by buildings.

The leading feature of this great undertaking, which up to 1888 had cost £6,824,877, was the interception of the sewage in its passage to the river, and its conveyance to a point well below London, here to be collected in reservoirs sufficiently large to prevent the necessity of discharging it, excepting at ebb tide, when it was turned into the river in its crude state. Embanking the river was also contemplated, though it was not till 1862 that the Board were entrusted with this work. Both the immense outfall reservoirs were completed and in use in 1864, by which date about one-third of the sewage had been diverted from direct communication with the river, the result being quickly perceptible in the improved condition of the river within the metropolitan area, though the death-rate, which between 1857 and 1860 had fallen to 23·7, rose between 1861 and 1870 to 24·4, the cholera epidemic of 1866 intervening. This outbreak in the East of London was considered by Dr. Netten Radcliffe to have arisen from the consumption of water taken from the Lea. In 1865 His Majesty, the late King, then Prince of Wales, formally opened the Crossness pumping station. The low-level sewer on the north side and the Embankment were not, however, fully completed until ten years later—1874.

Account of the Sewerage System.

The system as a whole at that time could be divided into four sections. First, the local sewers, collecting the sewage. These were administered by the various district boards, being under the supervision of the Board of Works to ensure uniformity. The second section comprises the main sewers falling from the higher ground to the river, many of them the converted water-courses; into these the local sewers are connected. The third section consists of the intercepting sewers, three on each side of the river, with certain branches. These great sewers radiate from Old Ford and Abbey Mills (see Fig. 1) on the north and Deptford on the south, spreading like a fan westward into three main branches. On each side one branch, the low-level intercepting sewer, rests on the river bank, the middle-level intercepting sewers are half-way up the rising ground, while the high-level intercepting sewers gradually rise to their highest points at Hampstead on the north and at Sydenham on the south; only in this last case it is called the Effra branch sewer, occupying the course of an old stream. The main trunks falls eastward, being the outfalls. In a measure they all run parallel to the river, and in their course intercept the several main sewers, running at right angles to them. The high-level and mid-level sewers fall by gravitation. The contents of the lower-level sewers have to be raised by pumping into the outfall sewers. The outfall sewers on either side discharged from the first into reservoirs at Barking and Crossness respectively, and these were capable of containing six hours' flow which had to be discharged at each ebb-tide.

There yet remain to consider the storm relief sewers. As far as possible sections of the old main sewers were utilised for this purpose. At certain points a new main sewer is brought side by side with an old one, and the two are formed into one large sewer or chamber for a short distance, when they again separate, the new one going to the outfall

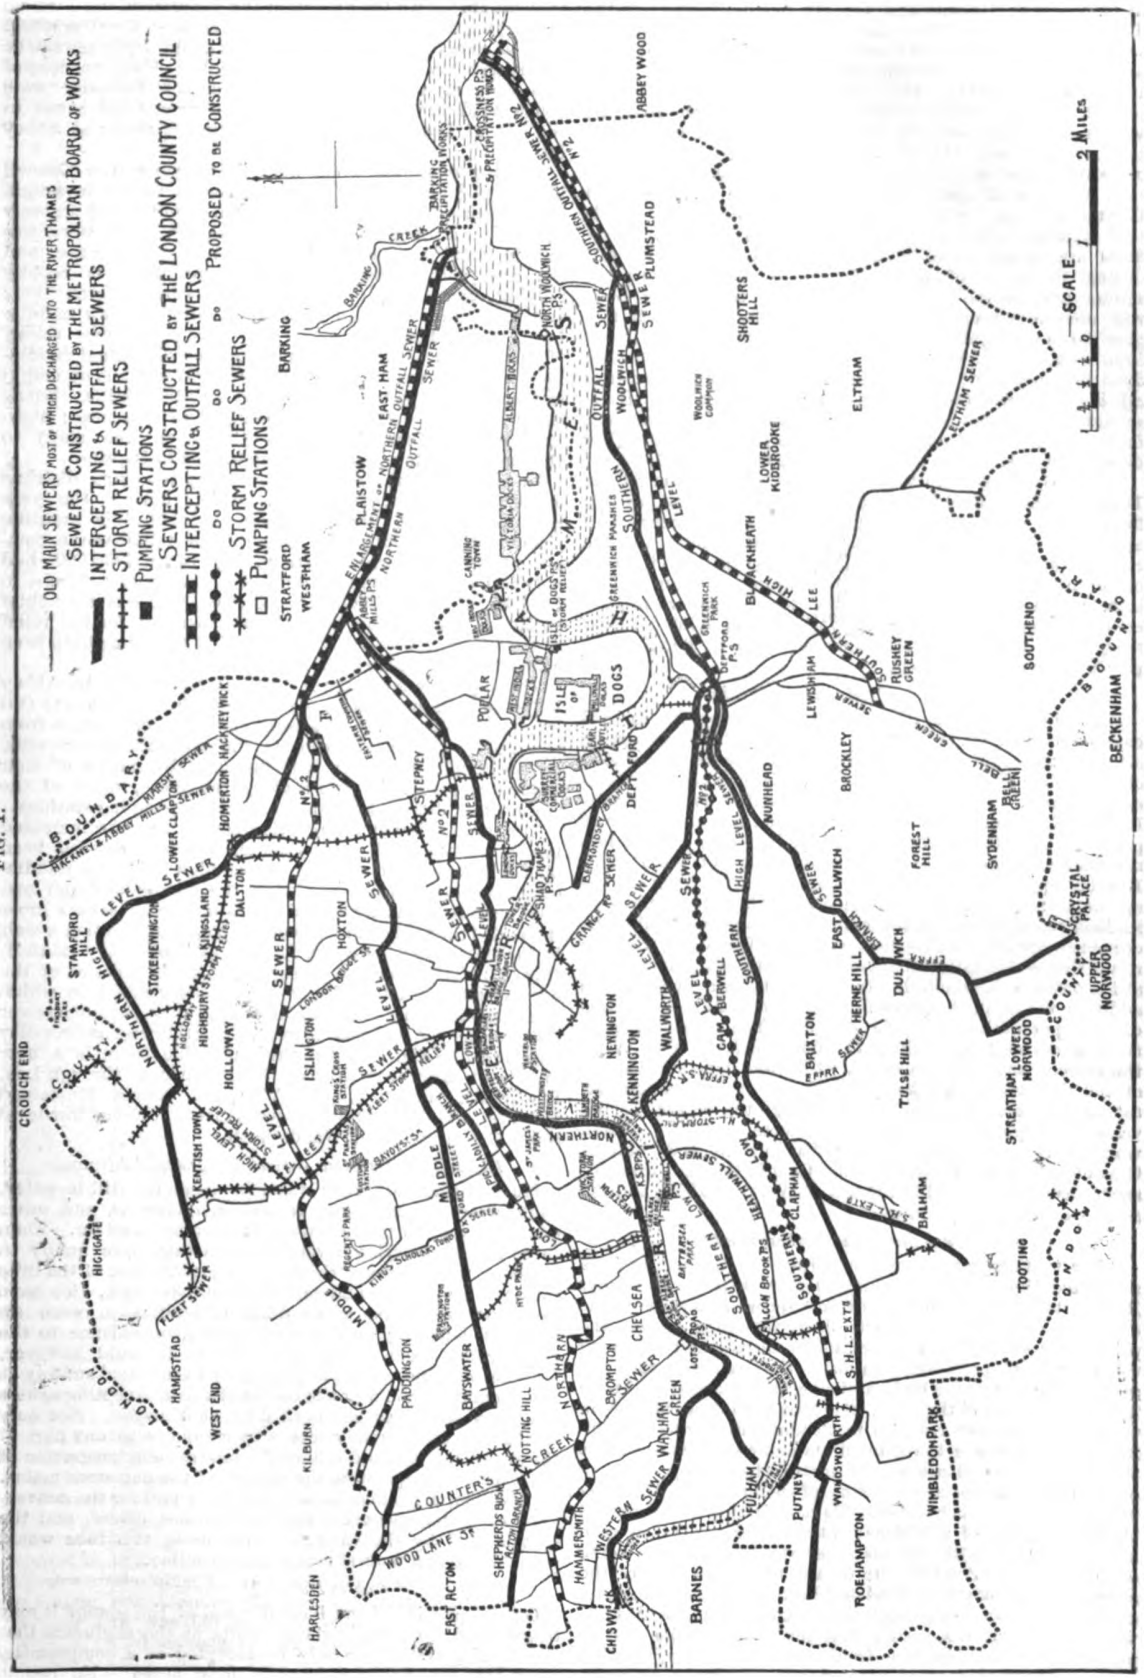

FIG. 1.

Map showing the various sewers and pumping stations in London. Old Ford, so often alluded to in the article, is not on the map; it is at F, just south-east of the spot where the northern high-level and new and old middle-level intercepting sewers meet.

at Crossness or Barking, and the old one delivering into the Thames as before. The chamber thus formed is divided longitudinally by a dwarf wall or weir (see Fig. 2). The storm water, pouring through the new main sewer, cleared it to a large extent of the normal sewage flowing to the outfall, but the rising water soon overflowed the dividing weir and escaped through the old relief sewer directly to the river, these old sewers discharging storm water on either side within the metropolitan area. This practice, which still maintains, was considered by the Royal Commission on Metropolitan Sewage Discharge (1884) the weakest point in the system. The storm overflows are incapable of dealing with exceptional rainfall during the time of high tide. The new intercepting sewers and provision for storm water now being built will doubtless remedy this evil. Ill fares it with any poor flusher caught by one of these sudden spates if far from a manhole. Warned by the roar of the approaching flood he must wade through the rising water to where a life-rail is fixed across the entrance of some branch sewer. Here, should his Davy lamp happen to get extinguished, he clings for dear life in total darkness until the storm abates. (For details of the sewerage system see Note G and Fig. 1.)

Difficulties arose with the old sewers used as storm reliefs. These only being able to discharge into the river at low tide flooded the surrounding district when a storm occurred at any other time. The inadequate provision made for the removal of this water was emphasised by the great increase of building causing the rainfall to find its way more rapidly into the sewers than before. The Board therefore in 1879 embarked upon additional relief works costing £708,000, and these were completed from time to time as floodings of property showed their need.

Construction of Precipitation Works.

Following soon after the opening of the system in 1864 complaints were made by those navigating the river and by others of the condition of the reaches in the neighbourhood of and below the outfall, which led to a protracted Government inquiry. This inquiry was held in 1869 by the late Sir Robert Rawlinson, but the charges were considered not proven. Complaints still continued to be made, and at last the City Corporation as sanitary authority of the Port of London approached the Home Secretary, resulting in the appointment of a Royal Commission in 1882. This Commission in 1884 reported against the existing practice of turning the crude sewage into the river at Barking and Crossness, with the result that precipitation channels were built over a large area at the outfalls, in which the sludge was thrown down by the addition of 1 grain of proto-sulphate of iron and of 4 grains of lime per gallon of crude sewage. The construction of these works at Barking alone in 1887 cost £473,000. After the effluent had been drawn off, which was done at all states of the tide, the sludge was pumped into tank steamers and taken out to sea to be discharged through the bottom of the vessel by means of specially constructed valves. These works were finally completed at Barking in 1889 and at Crossness in 1891 by the London County Council, who had succeeded the Metropolitan Board of Works in 1888; and the same system continues in use.

Additional Sewers and other Works.

After taking over the responsibility the Council in 1889 appointed the late Sir Benjamin Baker with Sir Alexander Binnie, its engineer, to inquire and report generally on the efficiency of the system, particularly regarding sewage disposal, with a view to the prevention of disease and to freeing the river from pollution. In brief they reported that the general features of the main drainage, they thought, had been unalterably fixed in the past; also that a want of capacity in the main sewers had resulted in floodings during heavy rainfall, at which times the diluted sewage was discharged into the river in the heart of the metropolis. They were of opinion that a certain amount of pollution in the river was inevitable at such times. To remedy this they proposed the construction of additional intercepting sewers on each side of the river with various other works, the whole being estimated at £2,250,000. In regard to the disposal of the sewage it was considered advisable to give the existing precipitation works a fair trial before constructing additional works at the outfalls, seeing that the river for the past 50 years had never been free from sewage pollution, but that practically little inconvenience had occurred. It was, however, thought that, with the growth of the population, the question of carrying the outfalls to a point lower down the river would have to be entertained, but in no case could crude sewage be discharged into the river. (See Note H.) Such portions of this work as were considered of urgent necessity were commenced in 1891, consisting of a new relief sewer in the Isle of Dogs, with additional pumping power at Abbey Mills.

Nothing more was done until 1899, when the Council instructed Sir Alexander Binnie to make a further investigation. He reported that large additional works were urgently required at a probable cost of £3,000,000. This work was put in hand in 1901; much of it is now in use, and the rest, with considerable additional work, is rapidly nearing completion. These works were:—North side: two outfall sewers, Old Ford to Barking; a new middle-level sewer, Paddington to Old Ford; low-level sewer, Hammersmith to Abbey Mills; extension of original middle-level sewer to Scrubbs-lane, Willesden (Wood-lane on map); and additional pumping machinery at Abbey Mills. South side: low-level outfall sewer, Deptford to Crossness; high-level sewer, Catford (Rushey Green on the map) to Crossness, and low-level sewer, Battersea to Deptford.

In 1903 the serious flooding of many low-lying districts owing to exceptional rainfall, which during the year amounted to 35 inches, again brought this question prominently forward, and though the relief works commenced in 1879, which were to cost some £708,000, had only just been completed, while others were in progress, in 1904 Mr. Maurice Fitzmaurice, C.M.G., who was then chief engineer, advised the Council to undertake further relief works at an estimated cost of £737,000. Some have been completed and others are still progressing.

The new low-level sewer from Hammersmith to Abbey Mills, and the new middle-level sewer from Kilburn to Old Ford, will relieve the old sewers of the normal output from the rapidly growing suburbs in the West and North-west. In addition to this they will intercept by means of weir chambers, placed at points along the route, much of the storm water flowing towards the riverside pumping stations.

The three original intercepting sewers are now increased to five on the north side—that is, a new sewer has been placed between, and parallel to, the high-level and middle-level sewers, and another between the middle-level and low-level sewers. The main and the storm-relief sewers cross these at right angles, and at certain points of junction a weir is placed to distribute the flow in case of heavy rainfall. (Fig. 2.) There are also, at several points of junction of the new system with the old, chambers constructed in which huge penstocks are fixed to divert the flow from one sewer into another for purposes of repair or otherwise as necessity may arise. (Fig. 3.) On the south side there is a new high-level sewer from Rushey Green (Catford), through Lee, Blackheath, Charlton, and Woolwich, across Plumstead Marshes, to the outfall at Crossness. Another low-level sewer is projected from Wandsworth.

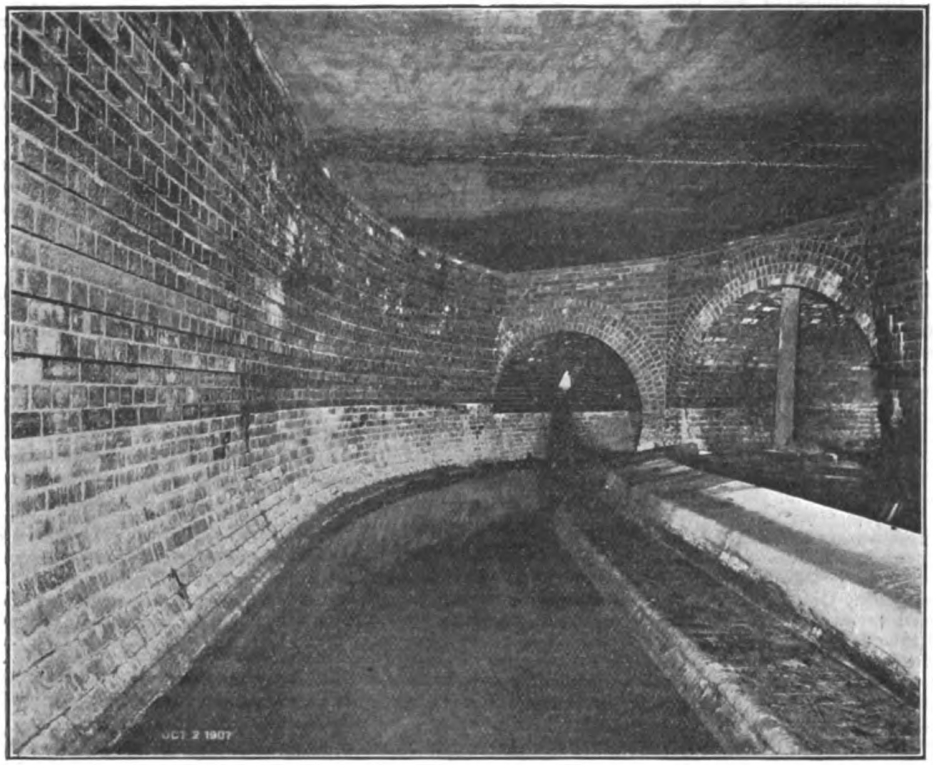
Difficulties Overcome.—Some Suggested Additions.

Much of this work is in districts abounding still in water, while water, electric, gas, telegraph, telephone, and other mains, as well as tube railways, have to be cared for. Then there are the varying levels of parts that have finally to coalesce, while many of the sewers are of the size of the tube railways themselves and of similar construction. To have overcome these and many other difficulties in such an extended and busy area with so little inconvenience to the public calls for our warmest admiration. It would, however, have been a welcome addition if a well-ventilated subway at a convenient depth over the course of the intercepting sewers had been added, as has been done at Aldwych. Not only would this afford ready access by manholes to any part of the sewer, but it would relieve the too frequent congestion of the streets consequent on the repairs of the numerous mains. In addition, a pneumatic tube might be laid for the conveyance of letters between the district post offices, and the rentals paid by the various bodies using this tube would probably yield a modest return on the outlay.

Public Health Questions.

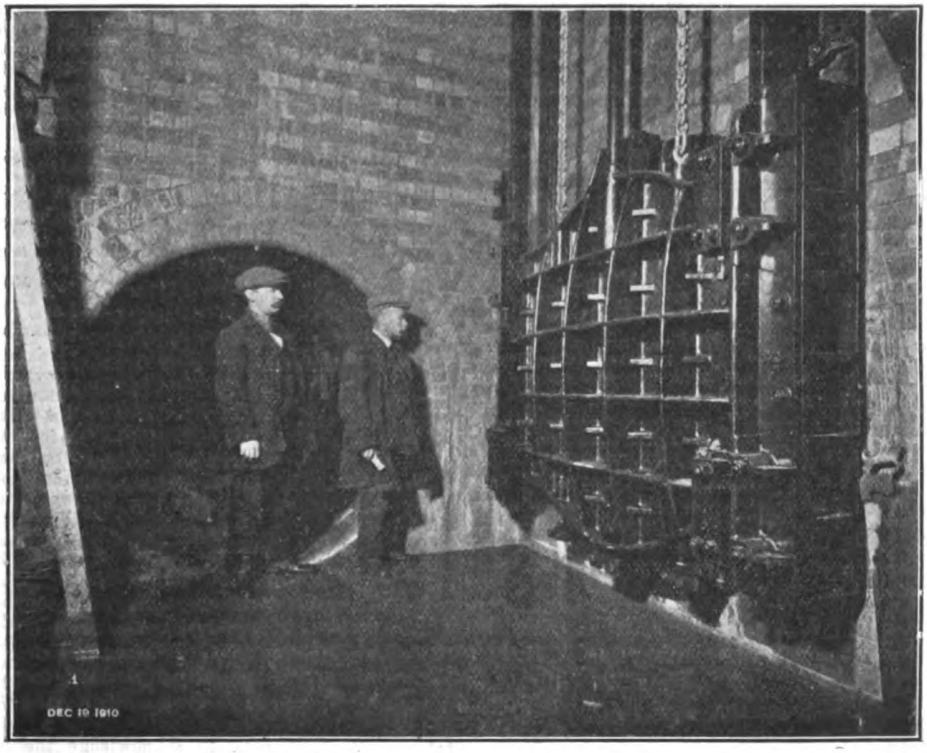
On the question of the final disposal of the sewage it may be gathered from the various reports of the engineers that the existing system can only be accepted as a compromise. With this every thoughtful man must agree. No people

FIG. 2.



Weir chamber in storm relief sewers.

FIG. 3.



Penstocks for diverting flow from one sewer to another.

have a right to pollute the pure waters of any river. Ruskin, in "A Crown of Wild Olives," on noticing this being done at the springs of the Wandle at Carshalton and Beddington, says: "I have never seen anything so ghastly in its inner tragic meaning ..... as the slow stealing of reckless, indolent, animal neglect over the sweetness of that English scene ..... than the insolent defiling of those streams by the human herds that drink of them." Speaking of the inhabitants he adds: "They have neither energy to cart it away nor decency enough to dig it into the ground, thus shed into the stream to diffuse what venom of it will float and melt far away in all places where God meant those waters to bring joy and health." It is certainly a primitive if not a barbarous expedient, though its avoidance is hedged about with difficulties. It may be taken as an axiom, however, that no outrage against any scheme of Nature is for long committed without a penalty.

How far sewage pollution affects the wholesomeness of fish drawn from a source subjected to such influence there has been, until quite recently, no definite record, saving in the case of oysters, mussels, and cockles, but it is well known that many people are unable to eat certain kinds of fish without considerable gastric disturbance. Some kinds of fish are notoriously dirty feeders. Suspicion has within the last few years fallen upon certain kinds of flat-fish—plaice, dabs, and flounders—the young of which frequent the shallow waters of the estuaries, where they feed upon shell-fish. Last year, owing to the character of an outbreak of typhoid fever at Bethnal Green and other of the poorer districts of London, the matter was made the subject of a more than usually exhaustive inquiry by the medical officers of the London County Council. The whole question is fully reported in an official publication by Sir Shirley Murphy, medical officer of health of the London County Council, which includes a report by Dr. W. H. Hamer on certain localised prevalences of typhoid fever in London in 1910. The association of a shortage in supply of small flat-fish at Billingsgate with a drop in the returns of typhoid cases is a significant matter, there being little sale for this fish when the price exceeds ½*d.* per pound. Owing to the hard nature of the food of these fish the usual practice may be omitted of gutting shortly after the catch. These small plaice are principally retailed as fried fish in the poorer districts, and if the cleaning is either omitted altogether by vendors or is carelessly performed the danger is obvious. The suspected supplies are chiefly derived from the northern grounds off the German coast, but they may come from other similar sources. The outbreaks of typhoid fever between 1908 and 1910 unquestionably originated from sewage pollution first affecting the shell-fish, and afterwards the fish and those who had partaken of them.

For many years ideas were prevalent that London sewage held a considerable manurial value, but such have been long since exploded. Its diluted condition and composite character render the many attempts made to secure the valuable nucleus abortive owing to excessive cost. The experiments of 1893 made at Barking for the bacteriological treatment of the sewage, conducted under the superintendence of Sir A. Binnie both by Mr. W. J. Dibden and afterwards by Dr. F. Clowes, are too well known to our readers to need description. (See London County Council Papers, 246, E. Stanford, Charing Cross, 2*d*.)

The fourth report of the Royal Commission on Sewage Disposal in 1904 furnishes the result of a biological examination of the water in the Thames taken from Barking and Crossness down towards the river mouth. The number of B. coli per cubic centimetre of water varied from 100 to 1000. An improvement was first noticeable at Purfleet 5 miles below Crossness, but not till Mucking was reached—15 miles lower down—was this very marked. Here the number varied from 1 to 10, but 5 miles lower down still (by the Chapman light not far from Leigh) it was only 50 per cent. of this amount.

Sewer Ventilation.

The difficult question of ventilation in this maze of sewers still leaves something to be desired. An ideal treatment would be a gradual and progressive purification from the moment the refuse enters the sewers, but the conditions present during its long passage to the outfall are such as to encourage putrefaction than rather to retard it. This is largely owing to the opposition of the public to all attempts made to ventilate the sewers. The absence of such ventilation, on an extended scale, is a principal cause of the nuisance complained of in the neighbourhood of the few existing ventilators. Aerating the stream of sewage by blowing into it jets of compressed or oxidated air at intervals during its passage might be of service. For instance, where the stream was sluggish it might serve the twofold purpose of accelerating the flow and of purifying the sewage at the same time. It would be a disappointment, however, if the effect produced was anything like that experienced at times in the neighbourhood of one of the patent sewage injectors when in action, but such questions are for the engineer.

The conditions of the sewers are to a large extent those of a long septic tank, in that much of the solid constituents, through the action of anaerobic bacteria, becomes liquefied and more easily dealt with at the outfall, though when there it will be more evil-smelling than when it entered the sewer. Mr. W. J. Dibden carried out some experiments at Barking with a view to improving the condition of the sewage by the injection of air with somewhat favourable results. Though the cost incurred did not warrant its application on a large scale, yet it might prove worthy of a trial in the sewers before putrefaction had commenced. Oxidation would arrest this process, but it is possible that the solid portions might be precipitated, in which case the flow, owing to the slight fall in the sewers, would not be sufficient to carry the sediment to the outfall. Against this possibility the idea of the injection of air as an aid to liquefaction of sewage was tried as far back as 1865 by Mr. Mechi at a sewage farm at Tiptree in Essex. The whole of the manure from certain stockyards was collected in an open septic tank holding 80,000 gallons; this was diluted with a definite proportion of water, and air was intermittently forced into the tank. Any kind of offal, including dead animals, was thrown in, and the whole fermenting mass quickly liquefied so that it could be pumped on to the land. The questions arising out of such processes can only be determined by those having practical experience.

Sewage Disposal a Serious Problem.

The principal lesson to be learned from all that has been set out is one of warning from the condition of London and the river in the middle of the last century. What are the conditions to-day? Large quantities of diluted sewage are still, in times of heavy rainfall, discharged into the stream in the heart of London. A combined total of 283,458,950 gallons of chemically treated liquid sewage is on an average turned into the Thames daily at Barking and Crossness, with the addition of from 7000 to 8000 tons of filth (sludge) which is daily carried out to sea. Think of it! The mind fails to form a just estimate of this huge polluted volume. London is, from its size, perforce the worst offender, but all round the coast, in our growing towns, in our health resorts, the same thing goes on, especially in our large cities situated on estuaries. For instance, to name a few:—

Belfast.—Six-sevenths of its crude sewage is discharged into the Lough.
Birkenhead and Liverpool.—The crude sewage is discharged at all states of the tide in the Mersey.
Bristol.—The bulk of the untreated sewage is discharged into the Avon at low tide.
Dublin.—The effluent from the precipitated sewage is turned into Dublin's beautiful bay.
Glasgow.—The effluent of the precipitated sewage is discharged into the Clyde at Dalmarnock and Dalmuir.
Hull.—The crude sewage is pumped into the Humber.
Southampton.—The sewage after partial subsidence is turned into the River Itchen on the ebb-tide.

In these towns alone in 1901 there was an aggregate population of 2,732,091. Surely such a condition of things cannot go on indefinitely, especially in view of the recent evidence of the effect produced by sewage-fed fish. Other fish than those caught in the North Sea form an article of diet. Many parts of our coast have been renowned for the flat-fish frequenting the bays and estuarian waters. Such facts as the foregoing demand serious consideration.

We conclude by expressing our best thanks for the courtesy shown us in this inquiry by the several officers of the London County Council to whom appeal has been made for information. Free use has been made of the published official reports connected with the main drainage of London, especially a very concise digest by the chief engineer, Mr. Maurice Fitzmaurice, while many well-known works of the past have been laid under contribution. Mr. Worth, the district engineer, kindly made arrangements for our representative to inspect the various works of the main drainage system. We also have to acknowledge the use of the

photograph for Fig. 3, lent by one of the contractors, Messrs. Griffiths and Co., of London Wall.

NOTES.

NOTE A. *The continual raising of the level of the ground.*—At the construction of the Victoria Embankment and the District Railway (1862-1870) the late Sir Benjamin Baker, the engineer of the railway, contributed some interesting records which confirm this view. At the City end as much as 24 feet of dust and ruins of ancient buildings were cut through; this varied in depth, but at Westminster it was 18 feet thick. At a depth of 8 to 16 feet below the present surface of the roadway a layer of peat was found 700 feet long and from 2 to 7 feet thick; also at Victoria Station a similar layer 200 feet long and 3 feet thick was met with at a depth of from 9 to 24 feet below the surface.

In making the excavations the gravel was generally found fairly dry to about the depth of the inverts of the adjoining sewers, but below that level large volumes of water existed.

Also in digging for the low-level sewer in the neighbourhood of West Ham peat was met with 12 to 14 feet thick, containing the remains of an ancient forest. This consisted of the stems of trees from 12 to 18 inches thick, having their roots in the clay. Below this layer was the old river gravel. Some leaden coffins were also found in West Ham Marsh.

NOTE B. *The former extent of the Thames at Westminster, &c.*—In an official record dated 1678 Sir C. Wren proposed important improvements in regard to "Ye new Sewers and Ye Backwater in St. Margaret's, Westminster"; and it is also well known that Birdcage Walk in St. James's Park had to be drained before constructing the aviary erected there for Charles II.'s pleasure. Stow, quoting Fitzstephen, refers to this backwater; he mentions a bridge near Whitehall over the Long ditch, "so called for that the same insulateth the City of Westminster." The late Rev. W. J. Loftie thought that "there is little doubt that in the days of Edward the Confessor there was a ford from Westminster to Lambeth." The water spreading over such a large tract of land about this point, it could not have been of any great depth. The ford would occupy the position of the old Horse-ferry; possibly Hungerford indicates a similar crossing.

It would have been much the same on the Lea. The water of the estuary, spreading over parts of Poplar and Canning Town as it did, would have made the lower reach by Stratford and Old Ford far more shallow than at present. This dangerous ford was superseded by the construction of the stone three-span bridge receiving the name of "the Bow" a short distance below the ford, built by Queen Maud, wife of Henry I. It was rebuilt in 1840. There might have been a ford across the Ravensbourne at Deptford, but this place gained its name from the Danes, being the deep fiord in which they anchored their ships when on the watch for plunder.

NOTE C. *Occurrence of floods.*—In 1236 the Thames overflowed, making Woolwich Marshes like a sea. Very many people were drowned, and much damage was done, Westminster Hall being flooded and people going into the Hall in boats. The same occurred in 1242, the river overflowing Lambeth hithe for a space of six miles, drowning many people and destroying houses and property.

Well on into the eighteenth century the Marshes left round Bermondsey, Lambeth, and St. George's Fields were uninhabited, save for the dwellers in a few squalid huts, some built on piles after the manner of lake dwellings.

NOTE D. *The Fleet River.*—The state of the Fleet River, as described by Swift in his "City Shower" about the middle of the eighteenth century, bears testimony to the little regard paid to enactments and to the neglected condition of the streets and water-ways at this time:—

> "Now from all parts the swelling kennels flow,
> To bear their trophies with them as they go;
> . . . .
> And in huge confluence joined at Snowhill ridge
> Fall from the conduit prone to Holborn Bridge;
> Sweepings from butchers' stalls, dung, guts, and blood,
> Drowned puppies, stinking sprats, all drenched in mud,
> Dead cats and turnip tops, come tumbling down the flood."

The more polished if less expressive line of Pope in the Dunciad bears a like testimony.

The Fleet, also called the River of the Wells, had its rise on the eastern side of Hampstead, and as a sewer has been diverted from its original course to drain Camden Town; then making its way through St. Pancras, it was joined farther on by a small branch from Clerkenwell. Reaching the Holborn Valley it absorbed the waters of the old Bourne, having its rise in Middle Row, and then by way of Farringdon-street into the Thames.

The main portion of the river was converted into a sewer in 1732 with the exception of a few sections, including one near the outlet, which last, at the building of Blackfriars-bridge in 1765, was carried out into the river in a culvert 18 feet wide and 12 feet high. The river was at one time navigable for some distance. As a sewer it drained a district covering an area of 14 square miles.

NOTE E. *Bermondsey.*—A description of this district is given by Dickens in "Oliver Twist," under the name of Jacob's Island.

NOTE F. *Details of the sewerage system: The outfall sewers.*—On the *north side* these outfall sewers run from Old Ford to Barking (see map), each measuring 9 feet over. They are connected with the high and mid-level intercepting sewers at Old Ford by gravitation, the contents of the low-level intercepting sewer being pumped into them lower down at Abbey Mills.

On the *north side* the high-level sewer commences at Hampstead, keeping on the higher ground as far as Stamford Hill, falling the whole way by gravitation through Clapton and Hackney to Old Ford; its length to this point, including branches, is 7 miles. It has a sharp fall of 50 feet or more to the mile at its commencement, which diminishes to 4 feet only near its termination, and is laid at a depth of from 20 to 26 feet, draining an area of about 8¼ square miles. It commences as a 4 ft. barrel, and is 9 ft. 6 in. by 12 ft. at its completion.

The mid-level sewer is laid at a depth of from 30 to 40 feet owing to its position on the lower slope of the hill; it measures 4 ft. 6 in. by 3 ft., increasing to a 9 ft. 6 in. by 12 ft. sewer on completion, and with branches it is about 13 miles long. Starting from Kensal Green it passes through Bayswater and along Oxford-street, where, near the British Museum, it receives a branch from Piccadilly; then by way of Old-street and Bethnal Green it goes to Old Ford, with a fall varying from 17½ to 2 feet per mile. It drains an area of 16¾ square miles. This is also a gravitation sewer.

The low-level sewer, with branches, is about 21 miles, increasing from 4 feet by 2 ft. 8 in. to a 10 ft. 3 in. barrel. Commencing at Chiswick, and passing through Walham Green, it receives a branch from Fulham and gravitates to a pumping station at Pimlico, where it is raised 18 feet; it is continued by the side of the river along the Embankment, through Limehouse, receiving branches from Hackney and the Isle of Dogs, Bow, and Bromley; it reaches Abbey Mills pumping station, where it is raised another 36 feet into the northern outfall on its way from Old Ford to Barking. It drains an area of 24 square miles.

On the south side the outfalls measure some 11 feet to 12 feet over-running from Deptford to Crossness. At Deptford the sewage from the low-level sewer is pumped up 18 feet into them. The other intercepting sewers connect to the outfalls by gravitation with the exception of the new sewer from Catford (Rushey Green on map), which runs by gravitation directly to Crossness, where it is lifted into the reservoir for treatment before discharging it into the river.

The sewage on the south side of the Thames is dealt with as follows:—The low-level sewer, 10¼ miles in length, starts in Putney with a 4 ft. by 2 ft. 8 in. sewer; keeping near the river, it passes through Wandsworth and Battersea to Vauxhall. It then runs near the Oval, Kennington, and turns in Camberwell New-road north-east, passing Walworth, near Albany-road, to the Old Kent road, from thence to New Cross and Deptford, where it passes into the pumping station by a 7 ft. by 7 ft. sewer. On its way it is joined by the Bermondsey branch sewer, 2¾ miles in length, the total area drained being 15½ square miles. The size of this branch sewer is a 5 ft. 6 in. barrel, and terminates at the pumping station in a 7 ft. by 7 ft. sewer.

At Deptford the sewage is lifted to a height of 18 feet, and discharges into two outfall sewers, each about 7½ miles long, and 11 feet 6 inches diameter, with a fall of 2 feet per mile. After taking various branch sewers in Greenwich, Woolwich, Plumstead, &c., these sewers discharge at Crossness, where the sewage is lifted some 20 feet by four beams and two vertical engines and pumps into precipitation channels, where it receives chemical treatment. The effluent eventually discharges over a weir into the Thames.

The southern high-level sewer commences at Balham in a 4 ft. by 2 ft. 8 in. sewer, it runs along Balham High-road to Clapham-road, where it increases in size to 4 ft. 6 in. by 3 ft. At this point it is joined by the Putney to Clapham extension sewer, commencing at Roehampton-lane as a 4 ft. 6 in. by 3 ft. sewer, and ending in a 9 ft. by 6 ft. sewer. From Landor-road, at its junction with Clapham-road, the combined sewage from the two branches mentioned above is carried in a 5 ft. barrel sewer through Brixton and Camberwell on to Deptford Broadway, where it ends in a 10 ft. 6 in. by 10 ft. 6 in. sewer. Near this point it discharges into the southern outfall sewer already mentioned. The total length of these sewers is 15¼ miles, and the area drained some 8½ square miles.

In addition to these, there is a high-level sewer from Catford, commencing in a 10 ft. barrel, increasing in size to a 11 ft. 6 in. barrel, which passes along Blackheath, Charlton, Woolwich, Plumstead, and thence in embankment to Crossness, where it discharges direct into the precipitation channels without the necessity of pumping, and is treated along with the other sewage already mentioned.

Other sewers known as the Effra branches, 7¼ miles in length, start from the Crown Hill and the Crystal Palace, and commencing in 4 ft. by 2 ft. 8 in. and 3 ft. by 2 ft. sewers respectively. These branch sewers join a 6 ft. barrel sewer in Park-road, West Dulwich, whence it flows through Dulwich and Peckham to New Cross and Deptford, and joins the southern high level sewer near the Broadway, ending in a 10 ft. 6 in. by 10 ft. 6 in. sewer, being connected into the southern outfall sewer, and thence to Crossness.

The total amount of sewage treated at Crossness annually is about 49,000,000,000 gallons, of which 281,000,000 reaches the reservoirs without pumping. 174,000 gallons of sewage can be raised per minute to a height of 20 feet at this pumping station.

The foregoing includes some of the recent additions:—There are 11 pumping stations, five of which are continuously employed in lifting the sewage from one level to another. The total indicated horse-power of these five stations combined is from 5000 to 6000. They are situated as follows (see map): Western pumping station at Pimlico; Abbey Mills; North Woolwich; Deptford; Crossness. The Western and North Woolwich stations can also be used for pumping storm water directly into the river. In addition to the above there are six other stations for discharging storm water into the river situated as follows (see map): Lots-road, Chelsea; King's Scholar's Pond, North west of Vauxhall Bridge; the Isle of Dogs; Falcon Brook, Vauxhall; Heathwall, Nine Elms; and Shad Thames. With the exception of the Isle of Dogs station, the motive power is gas, the total indicated being 4000 to 5000 horse-power

NOTE H. *Treatment of sewage.*—The London County Council, with a view to future necessities, has secured some 500 or 600 acres of land in the neighbourhood of the outfalls, to enable it to further develop the present system of treatment, though such treatment would do little more than keep pace with the increase of the population and keep matters at their present level. The storm overflows, however, continue to deliver diluted sewage into the river in the heart of London.

WORTHING HOSPITAL.—In spite of the very strong appeal that was made last year for increased subscriptions, the accounts of the Worthing Hospital, it was stated at the annual meeting on August 25th, showed a deficit of £267, or only £9 less than in the previous year. This is considered very disappointing, particularly as with the opening of the new out-patients' department, which is in course of erection, the expenses must necessarily increase. Unless the institution receives a good deal more support the position will become exceedingly serious. The number of in-patients during the year increased to 312 from 278 the year before, and the out-patients showed a slight decrease, this being probably due to the stricter inquiry that was made into the circumstances of applicants.

THE INTERNATIONAL EXHIBITION OF HYGIENE AT DRESDEN.

BY FLEET-SURGEON W. E. HOME, R N.[1]

(*Concluded from p. 548.*)

THE popular section of this exhibition, albeit so extensive and so carefully planned, is after all but a tiny part of the magnificent whole. The other sections and the pavilions of foreign nations were too many and too vast for me to visit them all in the few days I had. And of the exhibits one did admire one can only mention here a very few. A book recounting the recent advances in medicine, and apparently prepared by the Prussian Government for this exhibition, was attached to tables by a chain, and was everywhere in evidence. Each had a thick marker fixed in it, inclining it to open on the smallest provocation at the page which explained the neighbouring exhibits. I had been honoured a year ago by being asked to join the committee of the Naval and Military division, so after looking at the English Section, which owes so much to the indefatigable work of Mr. H. W. and Mrs. Armit, I went over to that division first.

Naval and Military Division.

The exhibits were most interesting and were attractively displayed in large halls. There was a section of the sick bay of a German battleship, very nice and light, the only wood used being the side pieces of the beds; the cabin of a fleet-surgeon, with neat little racks for his service books, and a mosquito-net diaphragm to fit in the window to keep out mosquitoes and prevent malaria. Perhaps the most surprising exhibit here was one in the Army Section indicating that there had been some anxiety about the frequency of tetanus after gunshot wounds. Investigations were made, and it occurred to somebody to examine the felt used as a wad over the explosive in the rifle cartridge; tetanus bacilli were found in it, and thereafter the felt was sterilised before the wads were cut. Could the principles of the Red Cross be more faithfully observed? There is a great Red Cross display, and Russia and Japan also show Red Cross exhibits.

Infectious Diseases.

Here is the pavilion of infectious diseases. It begins with a model of the Institute for the Study of Infectious Diseases in Berlin, with its many stables for beasts and runs for poultry; next there is a bacteriological laboratory equipment, with cages for small animals, various incubators and sterilisers, and apparatus for making culture media and preparing serums. Then follow animal plagues—e.g., swine fever; a picture of a sick pig, the methods of taking blood for examination, protective inoculation and the withdrawal of the protective serum (from the distal end of the caudal appendage), post-mortem appearances, and the microscopic pathology. The insects which convey diseases are displayed—the tiny glossina palpalis and the various ticks, and next, two rooms of bacterial and blood investigations. There is a large picture on the wall showing a man with hay fever; beside it the rye whose pollen is the most virulent cause of the disease (1-30,000th of a grain an effective dose). The swelling and vascular dilatation produced on an arm by subcutaneous injection are also pictured. Here is a collection of the cellular proteins of particular bacilli, shown by the University of Michigan; also the arrangements required for growing the bacilli in the huge quantities necessary. My attention was arrested by a bottle containing a tablespoonful of "the proteid poison from white of egg," which I had hitherto credited with but a doubtful objective existence. In the "immunity" room was an opsonin laboratory, and exhibits explaining the Wassermann reaction and salvarsan, and the applications of the deviation of complement to medico-legal work.

Cholera, plague, typhoid fever, and various other of the epidemic diseases have each a room, with maps to show the distribution and diagrams of the course of individual epidemics; the bacillus, in picture and in many cultures, and the lesions are also shown. I must mention the great collection of rodents, carriers of plague, shown by the Health Institute of Hamburg—rats, ground squirrel, wood rat, tarabagan—repeated to some extent in both the Japanese and English sections. In the small-pox room is a chart to show that of the few cases that did appear in Germany in the last few years, one quarter occurred in visitors from other countries; and another graphically displays that England and Belgium, which do not revaccinate systematically, have not really lost small-pox as have Sweden, Norway, Denmark, and Germany, which do.

Tropical Diseases.

The Section of Tropical Diseases was full of instruction. The malarial parasites, under the microscope and in pictures, in the blood and in course of development in the mosquito, were most copiously illustrated; also the prevention of malaria by curtains, boots, gloves, helmets. The fall of malaria in Italy since the serving out of quinine began is shown, and a similar curve appears in the Hungarian Section. Intestinal parasites and their development are exhibited; also the Leishman-Donovan bodies and sleeping sickness, its clinical and laboratory pathology, its epidemiology, and prevention are demonstrated. The whole exhibit, so complete and so clearly arranged, does credit to its president, Professor Nocht, and his able assistants in the Hamburg School of Tropical Medicine. There are, too, models of hospitals in the tropics, and the very attractive exhibit of the Wellcome Laboratories at Khartoum must on no account be missed.

Statistics of the World.

There is a room in which are displayed the statistics of the world. One could not say how far the figures noted were rigidly comparable, but from the curves which are shown deaths from tuberculosis appear to have decreased in the last 30 years most in Prussia, then in the German Empire, in Denmark, England, and Scotland; little improvement is noted in Ireland, Austria, or France. Here also are diagrams showing from the figures of the latest available census the distribution with regard to age and sex of the populations of many countries. There is a striking increase of the population under 10 in Spain, and a marked upspringing under 20 and under 10 in Bulgaria, Servia, Italy, Japan, and Egypt. This high increase in recent years is less noticeable in England and Scotland, and sadly deficient in South Australia and New Zealand. I am unable to give figures as photographing, sketching, or copying is forbidden in the exhibition. Another rather interesting set of tables mentioned in the catalogue I failed to see. They indicate for various towns the improvement in the vital statistics and the coincident expenditures on their public health services.

Tuberculosis and Venereal Disease.

Near this is the section for the care of the teeth, and beyond that of venereal diseases, with models of barracks which have sometimes been built for prostitutes, as well as a model examination room for them. The effects of venereal disease are shown by charts and wax models, syphilis insontium is also dealt with, how it occurs and may be prevented, and there are quantities of White Cross literature. The public opinion of Germany appears equally concerned in putting down venereal disease and tuberculosis. So great having been Germany's success against small-pox who will deny the possibility of its triumphing over these others also? In a wooden house in the grounds is a "Wandermuseum" of tuberculosis—the travelling caravan exhibits. Their success has been such that Dr. Mollow, in Bulgaria, has copied the idea and used it with great effect against malaria. So far as I can judge, the first principle on which they insist is that where there is no dust there is little danger of infection. The consumptive is taught to be very careful himself, and then they trust to exalt resistance by ensuring good nutrition, by impressing the need for extreme care of the teeth and showing people which are the most nourishing foods. They do not insist, as we do, on the open window, which one German medical officer of health considered impossible because of the rigour of their winter climate.

Other Pavilions.

I can only mention some of the other pavilions: the historical, showing the hygiene of Assyrians, Jews, Romans,

[1] The first section of this article was also written by Fleet-Surgeon Home.

and savage nations, is delightful; housing—warming of buildings and lighting, laundry machinery, furniture, basins and baths of all sorts, ventilation apparatus; rescue arrangements against drowning and accidents in mines; transport, including one of the wagons seen on German railways for carrying living fish in tanks; industrial diseases, with the clothing and exhaust fans employed to prevent anthrax; workmen's insurance, showing in great detail the working of the insurance laws; model dwellings—in this pavilion I was much struck by the compactness and small size of the German cooking stove.

Of the pavilions of other nations the Chinese is the most ornamental; the quantity of lacquer that met the eye had a sumptuous effect, and the beauty of the embroideries, that subserved the great cause of hygiene because they were bed-quilts, was most marked. Here was the famous soya bean with the old sauce, soy, and milk, oil, biscuits, jam, Italian pastes, and a cheese all made out of it. The Russian pavilion is the largest. Here, as in the French pavilion, great stress is laid on vaccination. The Hungarian Section is strong on the care of children. There is in the centre a great relief model of Hungary which shows the trouble they must have with malaria. The colour scheme and patterns of decoration have the beauty and individuality that anyone would expect who had ever been in Budapest. Fuji dominates as one enters the Japanese pavilion. Vaccination again is prominently set forth, and the cause and management of beri-beri. The foods of the nation are shown (1) as grown; (2) as in trade; and (3) as cooked, in little dishes. The work done by children in the schools is shown and there are two beautiful cases of their toys. The Austrian section is large and notable for its many rooms, each displaying the sanitary equipment or curative advantages of a single town. The city of Amsterdam is brave enough to be responsible for a single but admirable pavilion; its best exhibit is in the statistical room of the general exhibition.

The English Section.

The English section is in a different position altogether from the others, which are established by their respective Governments, while ours had to depend on private subscription. It is full of instructive exhibits, which have severely taxed the skill of Mr. Armit to display in the limited space available; but he has succeeded magnificently, and is making the collection all the more useful by his daily lecture at 3 P.M. The invaluable assistance he has had from Mrs. Armit was recognised by Professor Dr. Renk, the second president of the exhibition, when publicly opening the section. Their only other assistant is Miss Wright, who has come to demonstrate the Marylebone Dispensary's exhibit of its methods for the protection of infant life. The section, thanks to the help of the Board of Education, is very strong on the school side. Tropical medicine is particularly well shown, and the case of wax models of cancer, syphilis, and skin diseases, shown by Dr. G. Stopford Taylor and Dr. R. W. McKenna of Liverpool, attracts so much attention that brass rails were being put round it when I left to keep the glass from being always broken by people leaning on it.

In conclusion, I can only add, in case anyone fears that the sight-seeing would be altogether too strenuous, that quiet rooms may be hired, behind the Japanese pavilion, for 1*s.* an hour of an afternoon, and a long chair on the grass for 6*d.*, which things show a deal of consideration on the part of the administration, and give the sightseer an opportunity to reflect peaceably on the wonders seen.

THE BRITISH MEDICAL MAN ABROAD.

(*Concluded from page 657.*)

CANADA.

THE possession of British diplomas and degrees will in many cases entitle the holders to practise in Canada after having obtained a licence from the provincial medical boards and paid certain fees. It is hoped that a general principle of reciprocity will soon prevail.

Ontario.—Registration by the Council of the College of Physicians and Surgeons of Ontario is necessary, and it is optional for the Council to admit to registration all persons who are duly authorised to practise medicine, surgery, and midwifery in the United Kingdom and Ireland upon terms which the Council may deep expedient. The British medical man desiring to practise in Ontario should make full inquiries and ascertain his exact position beforehand, or he may be sadly disappointed.

Quebec.—Practitioners must be licensed and registered by the Provincial Board, which may license without examination holders of medical qualifications from British universities or corporations.

New Brunswick.—Practitioners in New Brunswick must be registered by the Medical Council of the province. A candidate for registration (1) must pass an examination in English, arithmetic, algebra, geometry, Latin, elementary mechanics, elementary chemistry, history, geography, and two of the following languages, Greek, French, and German, unless he has already matriculated at some College in the United Kingdom, Canada, United States of America, or Europe, or holds a first-class teacher's licence from the Board of Education of New Brunswick; (2) he must afterwards have studied for four years and attended some university or college or school of medicine for four sessions of not less than six months each and have attended lectures on anatomy, pharmacy, &c.; (3) he must have attended the general practice of a hospital for 12 months; (4) he must have obtained a degree in the above subjects from a university, college, or school requiring such four years' course of study or must have passed an examination in them before the examiners in New Brunswick; and (5) he must be over 21 years of age. Every candidate for registration as a practitioner, whether or not he has a degree or diploma, must pass an examination. A fee of $10 is required and medical practitioners are liable to an annual fee of from $1.

Nova Scotia.—Registration and a licence from the Provincial Medical Board are required, which admits to the privileges of practice, upon payment of the registration fee, all persons who are duly registered by the General Medical Council of Great Britain. The fee is $30.

Prince Edward Island.—No one can practise medicine, surgery, or midwifery in Prince Edward Island unless registered or licensed by the Council of the Medical Society of Prince Edward Island. The Council admits to the register any person who is duly registered by the General Medical Council of Great Britain.

British Columbia—No person may practise medicine, surgery, or midwifery in British Columbia unless registered by the College of Physicians and Surgeons of British Columbia. The Council admits to the register any person "who shall produce from any college or school of medicine and surgery, requiring a four years' course of study, a diploma of qualification," on proof of identification and on passing an examination as to his competency. The fee for registration appears to be rather indefinite, as we learn that it "must not exceed $100." Licences to practise are issued to women.

Manitoba.—Registration by the Council of the College of Physicians and Surgeons of Manitoba is necessary, and applicants for registration must be members of an incorporated medical body in Canada giving similar privileges to persons incorporated in Manitoba. Application should be made to the Council by British medical men desiring to practise in the province. The fee is $75. Licences to practise are issued to women upon the same terms as men.

Alberta.—Medical practitioners must be registered by the Council of the "College of Physicians and Surgeons of the Province of Alberta." The Council admits to the register anyone who (1) produces a diploma of qualification from any college or school of medicine and surgery which exacts for such diplomas attendance on at least a four years' course of lectures of at least six months each; (2) gives proof of identification; (3) passes before them a satisfactory examination appertaining to the profession of medicine and his fitness and capacity to practise medicine, surgery, and midwifery; and (4) pays $50, and another $50 for registration.

Saskatchewan—No one may practise in Saskatchewan unless registered (fee $50) by the Council of the "College of Physicians and Surgeons of the Province of Saskatchewan." The Council admits to the register anyone who produces a diploma of qualification from any college or school of medicine and surgery recognised by the Council, which requires attendance at a four years' course of lectures, and who passes an examination (fee $50) before the Council.

AUSTRALIA.

Legally qualified British medical men can practise in all parts of Australia. Proof of registration by the General

Medical Council of Great Britain must be submitted to the medical board of the particular State selected when a certificate to practise is granted. The medical man with British qualifications who desires to practise in Australia must communicate with the medical board as soon as he intends to settle, so that he may regularise his position from the beginning.

NEW ZEALAND.

Registration in the colony of New Zealand is obtained by the legally qualified British practitioner on producing his proof of registration by the General Medical Council of Great Britain and on paying a fee of £1 5*s*.

BRITISH SOUTH AFRICA.

The position of the legally qualified British practitioner in South Africa is much the same whichever colony he proposes to practise in.

Cape Colony.—No person may practise in Cape Colony as a medical practitioner without a licence signed by the Colonial Secretary of the province and the recommendation of the Colonial Medical Council is required. The fee for the licence is £5 and women are eligible for the licence. Applications should be made to the Colonial Medical Council at Cape Town.

Natal.—Here also application for a licence to practise medicine in the colony must be made to the Colonial Secretary of the province. The application will be granted upon the approval of the Natal Medical Council.

Southern Rhodesia.—The admission fee for the practice of medicine in Rhodesia is £5, and application for the licence should be made to the Chief Secretary, Salisbury, Rhodesia. It would be well also to write to the Secretary of the British South Africa Company, London Wall, E.C. In *North-Western Rhodesia* the fee is also £5.

Transvaal and the Orange River Colony.—The Transvaal Medical Council (Pretoria) and the Medical and Pharmacy Council of the Orange River Colony, Bloemfontein, grant a licence to practise on payment of £10 and £7 10*s*. respectively. Proof of registration by the General Medical Council of Great Britain must be supplied.

THE COLONIAL MEDICAL SERVICE.

In the following Colonies and Protectorates there are medical departments regulated from the Colonial Office:—British Guiana, Jamaica, Trinidad, Windward Islands, Leeward Islands, British Honduras, Fiji, Sierra Leone, Gambia, Gold Coast, Northern and Southern Nigeria, East Africa and Uganda Protectorates, Nyasaland, Somaliland, Ceylon, Straits Settlements, the Federated Malay States, Hong-Kong, Mauritius, Seychelles, Cyprus, Gibraltar, St. Helena, and the Falkland Islands. In Ceylon, Jamaica, and Mauritius vacancies are almost always filled locally by the appointment of qualified native candidates. As a rule, officers are required on appointment to undergo a three months' course of instruction at the London or Liverpool School of Tropical Medicine, and to obtain a certificate of proficiency before taking up their appointment. It is for the East and West African Colonies and Protectorates that medical officers are chiefly required. The majority of the West Indian appointments involve medical charge of a district, including, as a rule, the care of a hospital, poor-house, asylum, or other institution, and free attendance on the aged and children. Passage money on first appointment, and leave of absence on half-pay (in addition to the ordinary annual vacation on full-pay, not exceeding three months in two years), are granted only in the cases specified in the Colonial Regulations. Leave on half-pay is not granted before the completion of six years' service, except on the ground of illness or urgent private affairs. With regard to pension, medical officers are usually on the same footing as other Government servants; but in cases where private practice is allowed the rule is that they are not usually entitled to pension. In Ceylon, Straits Settlements, the Federated Malay States, Hong-Kong, and Mauritius all permanent Government servants are called upon to contribute 4 per cent. of their salaries towards the pensions of the widows and orphans of public officers.

British Guiana.—There are 40 appointments. Candidates must have held for at least six months a resident medical appointment in some public institution. Officers are appointed on two years' probation as assistant medical officers, and are paid a salary at the rate of £300 per annum with quarters, without the right to private practice. The permanent staff, to which officers may be appointed at the expiration of the probationary period, include the following appointments: Surgeon-general, £900, with travelling expenses and consulting practice; medical inspector, £800, with travelling expenses and private practice; 3 medical officers at £600 to £700; 10 medical officers at £560 to £600; 11 medical officers at £400 to £500; and 3 medical officers at £400. Medical officers appointed to districts receive travelling allowances varying with the nature of the district. They are also allowed private practice. Medical officers attached to public institutions are, in general, allowed free quarters. A deduction of 4 per cent. is made from their salaries for the payment of the premiums on an insurance of the officer's life for the benefit of his widow or orphans. The Governor has the power to appoint private practitioners to perform the duties of medical districts on temporary agreements, and in recent cases vacant appointments have been filled in this way, but it is not proposed to make such appointments in future.

Jamaica.—The appointments number 54 and are mainly district appointments, private practice being allowed; the salary paid by Government varies from £100 to £250 per annum. Newcomers are in some cases attached for a while to the public hospital in Kingston and given an allowance at the rate of £200 per annum, but not permitted to undertake private practice. Some medical officers receive a varying capitation allowance for attendance on immigrants. All medical officers are obliged to subscribe at the rate of 4 per cent. on their salaries towards the pensions of officers' widows and orphans.

Trinidad and Tobago.—In Trinidad and Tobago there are 35 appointments. Under the terms of the Ordinance regulating the medical service officers are appointed in the first instance on two years' probation as supernumeraries. They receive a salary of £250 per annum, with furnished quarters, and are usually attached to the Government hospital; the salary assigned to the district appointments, to which they are promoted as vacancies occur, is £300, which is increased to £400 and upwards by various allowances for horse, house, or otherwise. These posts carry the right to private practice. After every five years' service an officer is given an additional personal allowance at the rate of £50 per annum. All officers are required to contribute 4 per cent. of their salaries for the provision of widows' and orphans' pensions. In a few districts a system has been introduced by which the work is performed by private practitioners under temporary contracts.

Windward Islands (Grenada, St. Lucia, St. Vincent).—The 22 appointments are, with few exceptions, district appointments with the right to private practice attached; the salaries paid by Government vary from £250 to £400, with allowances in certain cases. The Governor has the power to transfer a medical officer from one island to another at his discretion. The appointments are not pensionable.

Leeward Islands (Antigua, St. Christopher and Nevis, Dominica, Montserrat, Virgin Islands).—The 25 appointments are of the same nature as in the Windward Islands. An officer when first sent out is not appointed to a particular island, but to the service of the Leeward Islands, with a salary of £250, and the Governor decides as to the district which is to be allotted to him. He is liable to be transferred at the Governor's discretion to any medical district in the Leeward Islands, and in certain districts may be required to perform magisterial duties. The medical officers receive fees for successful vaccinations, post-mortem examinations, attendance and giving evidence at courts of justice, certificates of lunacy, and, in the larger islands, for burial certificates. They are also, as a rule, allowed private practice.

British Honduras.—There are five medical appointments (besides the principal post of colonial surgeon). One of the medical officers is paid $1458 a year, two are also district commissioners and receive $1944 for the combined posts of medical officer and district commissioner, and one receives $750 a year, and is entitled to private practice, but not to pension. Unless they already possess a diploma of public health, medical officers are liable to be required before they join the colony to undergo a course of instruction at a laboratory of public health or analogous institution. The dollar equals about 4*s*. 2*d*.

Fiji.—The Government medial officers receive a salary of

£300, rising by annual increments of £25 to £500, with free quarters, or a house allowance of £50. In some districts a medical officer is also a magistrate with a combined salary of £500, rising to £600. They are allowed private practice, so far as is consistent with the proper discharge of their duty to the Government, but in most districts the private practice is very small. They are required either to take charge of hospitals or of districts, at the discretion of the authorities. The posts are pensionable. There are at present 15 medical officers, in addition to a chief medical officer (£700 a year, rising to £800).

Ceylon.—The principal civil medical officer receives £1250, rising by annual increments of £50 to £1400 per annum. There are an assistant principal civil medical officer on £750 by annual increments of £50 to £850, and a medical superintendent of lunatic asylum on £600–£800. The registrar of the Medical College, Colombo, and the director of the Bacteriological Institute receives £450–£600; the medical superintendent of the General Hospital, Colombo, £600–£800. There are nine provincial surgeons (Rs. 6000–Rs 8400), 30 first grade medical officers (Rs. 3600–Rs. 5400), 34 second grade (Rs. 1800–Rs. 3000), and 70 third grade (Rs. 1200–Rs. 1800). Private practice is allowed to the subordinate officers, but the colonial surgeons may take only consultation practice. The medical service of Ceylon is mainly recruited from among gentlemen born in the island, but possessing British diplomas.

Straits Settlements.—Two house surgeons in the General Hospital, Singapore, and two in the General Hospital, Penang, on £300, with free quarters. There are about 20 subordinate posts in the medical department, with salaries varying from £300 (rising to £360) to £780 (rising to £900). Some of these posts have free quarters attached, and the holders of some are allowed private practice within limits. The salary of the principal civil medical officer is £1000.

Federated Malay States.—Appointments are graded as follows: Principal medical officer, £1200; senior medical officer, Perak, £900, by annual increments of £20 to £1020; senior medical officer, Selangor, £780, by annual increments of £20 to £900; eight medical officers, Grade I., £600, by £20 annually to £720, with free unfurnished quarters; 13 medical officers, Grade II., £420, by £15 annually to £600, with free unfurnished quarters; house surgeons £300, rising to £420, with free furnished quarters without private practice. A medical officer is attached to the regiment of Malay States Guides, his salary being £360 to £480. The two senior medical officers and the two Grade I. medical officers in charge of Negri Sembilan and Pahang are allowed consulting practice only. Other medical officers are prohibited from private practice except in very special cases where the Resident General is satisfied that, owing to the absence of private practitioners, it is absolutely necessary to allow the Government medical officer to attend to private patients. The posts of medical officer, Grade II., in the Federated Malay States and the corresponding appointments in the Straits Settlements are filled by the promotion of officers who have entered the service as house surgeons.

Hong-Kong.—Principal civil medical officer, £800, rising to £1000. There are five medical officers, two health officers of the Port, and two medical officers of health, with salaries of £480 rising to £720. Most of these appointments are pensionable. Private practice is not allowed, and free quarters are only given in a few cases. The Government bacteriologist receives £480, rising to £720; and his assistant, £360, rising to £420. In Hong-Kong, officers whose salaries are fixed in sterling are paid locally in dollars, at a rate of exchange fixed monthly by the Government and based on the average exchange value of the dollar during the preceding month. When, however, the average exchange value for the month exceeds 2*s.*, sterling salaries are converted at 2*s.* to the dollar. In the Straits Settlements and Federated Malay States sterling salaries are converted at the Government rate of exchange, which is at present 2*s.* 4*d.* to the dollar. Vacancies in Hong-Kong are almost invariably filled by promotion or by transfer from other colonies.

Mauritius.—There is a headquarters staff, consisting of a director (Rs 10,000), an assistant director (Rs. 8000), two sanitary wardens (Rs. 6000), one assistant sanitary warden (Rs. 5000), an assistant medical officer, Port Louis (Rs. 5000) a police and prisons surgeon (Rs 6000), and a health officer (Rs. 5000). There is also a medical inspector attached to the Immigration Department. In the rural districts there are various medical officers, most of whom receive Rs 6000 a year and are not allowed private practice. Free quarters are not given in most cases. The service is mainly recruited locally. Officers in the service of Mauritius are required annually to contribute 2 per cent. of their salaries towards their pensions.

Seychelles.—There are four medical appointments. The Government medical officer receives Rs 4500. The assistant Government medical officers receive Rs. 3000. The holders of these latter appointments have free quarters. Private practice is allowed.

Gibraltar.—There is a surgeon of the Colonial Hospital receiving £275, £55 as medical officer of the civil prison and lunatic asylum, and horse allowance of £42, with private practice. There is also an assistant surgeon with a salary of £300 per annum, but without private practice, who is police surgeon, port surgeon, and surgeon to the Port Office without additional emoluments.

Cyprus.—There is a chief medical officer paid at the rate of £500 per annum, and three district medical officers paid at the rate of £275 per annum, all enjoying private practice (except the chief medical officer, who is allowed consulting practice only) and receiving 2*s.* per diem forage allowance; these are the only medical appointments in the island which are open to English candidates.

St. Helena.—The colonial surgeon at present receives £270 per annum, and £27 horse allowance. Private practice is allowed.

Falkland Islands.—There are two appointments, one of which is paid at the rate of £300 per annum, with £25 as health officer, and the other at the rate of £200 per annum, with £36 as deputy postmaster. The holder of the latter post is required to enter into an agreement with the West Falkland Medical Association, in accordance with which he renders professional services to the members of the association and their families, their employés, and their families, in return for £200 a year and certain payments by the employés. Private practice is allowed to both officers.

East Africa, Uganda, Nyasaland, and Somaliland Protectorates.—The salary of a medical officer on the permanent establishment in these Protectorates is £400 per annum, rising to £500 per annum by annual increments of £20. There are 14 appointments of this rank in the East Africa Protectorate, 11 in Uganda, seven in Nyasaland, and two in Somaliland. In the East Africa Protectorate there are certain special appointments—viz., a medical officer of health at Mombasa (£500 by £20 to £600) and two senior medical officers (£500 by £20 to £600). The salary attached to the appointment of principal medical officer in the East Africa Protectorate and in Uganda is £750 per annum, rising to £850 per annum by annual increments of £25, and £500 per annum, rising to £600 per annum by annual increments of £25, in the case of Nyasaland. Medical officers are permitted to take private practice on the understanding that they give precedence to their official duties. Free passages are provided to the Protectorates. Under the leave regulations officers are entitled to two months' leave on full pay every year, subject to the exigencies of the service, and are allowed to accumulate this leave up to six months—i.e., medical officers of the East Africa, Uganda, and Somaliland Protectorates who remain at their posts without intermission for 20 months are entitled to four months' leave; if for 25 months, to five months' leave; and if for 30 months, to six months' leave, but of such leave the first three months only are on full pay, the remainder being on three-fourths pay. In Nyasaland the amount of leave is the same, but the whole of the accumulated leave is on full pay. A vacancy occurring in the medical staffs of the East African Protectorates is at present usually filled by the absorption of one of the temporary medical officers whose appointments (at a salary of £400 a year) have been created in order to cope with the work in connexion with the extended investigation of sleeping sickness. There are seven of these temporary medical officers in Uganda, two in the East Africa Protectorate, and one in Nyasaland. A candidate for the East Africa and Uganda service will therefore in general be offered one of these temporary appointments in the first instance and will be considered for absorption, if he wishes, when an opportunity occurs, provided that his service is approved. Temporary medical officers are engaged for three years and free passages are provided.

All applicants for medical employment in these colonies must be between the ages of 23 and 35. (In the case of

East Africa, Uganda, Nyasaland, and Somaliland preference will be given to candidates who are over 25 years of age. (In the case of Fiji preference will be given to candidates who are under 30.) Preference will be given to those who have held hospital appointments as house physicians and house surgeons; testimonials to character and professional competence will be required, and every officer before being appointed will be medically examined by one of the consulting physicians of the Colonial Office: Sir Patrick Manson, 21, Queen Anne-street, Cavendish-square, London, W.; Dr. Hawtrey Benson, 57, Fitzwilliam-square, Dublin; and Lieutenant-Colonel J. Arnott, I.M.S., 8, Rothesay-place, Edinburgh.

Applications for medical employment in these colonies from persons in the United Kingdom must be addressed to the Assistant Private Secretary, Colonial Office, Downing-street, S.W.

West African Medical Staff.—The medical services of the West African Colonies and Protectorates, namely, the Gambia, Sierra Leone, the Gold Coast (including Ashanti and the Northern Territories), Southern Nigeria, and Northern Nigeria, form one service under the above name. All the medical officers for the service are selected by the Secretary of State for the Colonies, and are on one list for employment and promotion. Preference will be given to unmarried candidates. Married ones are not excluded, but it should be remembered that passages for wives and children are not provided by the Government, and that houses for them are rarely available. Officers should not take their wives out with them until they have acquired experience of the local conditions, and have obtained the sanction of the Governor.

The grades and emoluments of officers of the staff are as follows:—

Principal Medical Officer.—The principal medical officers receive salary as follows: In Northern Nigeria and Southern Nigeria, £1000 a year, rising by annual increments of £50 to £1200 a year, with a duty allowance [1] at the rate of £200 a year. In the Gold Coast £1000 a year, without increments, but with a duty allowance at the rate of £200 a year. In Sierra Leone, £800 a year, rising by annual increments of £50 to £1000 a year, with a duty allowance at the rate of £160 a year. There is no principal medical officer in the Gambia.

Deputy Principal Medical Officer.—There are three appointments of this grade, in Northern Nigeria, Southern Nigeria, and the Gold Coast respectively. Salary at the rate of £800 a year, rising by annual increments of £25 to £900 a year, is attached to these appointments, together with a duty allowance at the rate of £160 a year.

Senior Sanitary Officer.—There are four appointments of this grade, one each for Northern Nigeria, Southern Nigeria, and the Gold Coast, and one for Sierra Leone and the Gambia. Salary at the rate of £800 a year, rising by annual increments of £25 to £900 a year, is attached to these appointments, together with a duty allowance at the rate of £160 a year.

Provincial Medical Officer.—There are four appointments bearing this title, two in Southern Nigeria and two in the Gold Coast, with salary at the rate of £700 a year, rising by annual increments of £25 to £800 a year, and duty allowance at the rate of £140 a year.

Senior Medical Officer.—There are eleven appointments of this grade, with salary at the rate of £600 a year, rising by annual increments of £25 to £700 a year, and a duty allowance at the rate of £120 a year.

Junior Sanitary Officer.—There are four appointments of this grade, with salary at the rate of £600 a year, rising by annual increments of £25 to £700 a year, and a duty allowance at the rate of £120 a year.

Medical Officer.—The salary attached to this grade is at the rate of £400 a year, rising by annual increments of £20 to £500 a year. There is no duty allowance. Medical officers who have served for five years and are recommended for a higher rate of salary are required to take a special course of study for three months. If they obtain satisfactory certificates at the end of the course they are placed, on completing six years' service, on a scale of salary at the rate of £525 a year, rising by annual increments of £25 to £600 a year.

Every candidate selected for appointment will, unless the Secretary of State decides otherwise, be required to undergo a course of instruction for two or three months either at the London School of Tropical Medicine, Royal Victoria and Albert Docks, E., or at the Liverpool School of Tropical Medicine at University College, Liverpool. The cost of the tuition fees, board, and residence during such instruction, amounting to a maximum of £48 8*s.* 10*d.*, for three months, will be borne by the Government in the case of the London school; at Liverpool the cost of tuition will be borne by the Government, but candidates must make their own arrangements for board and lodging; an allowance of £2 a week will be paid to them monthly in arrear for this purpose.

The ordinary tour of residential service is one year, followed by leave with full pay during the voyages to and from England, and for four or two months clear in England, according as the officer is returning for further service in West Africa or not. Free passages are given to all officers who are granted leave, and free passage is also given on first appointment, subject to the officer signing an agreement under which he is liable to refund its cost if he relinquishes his appointment for any other reason than physical or mental infirmity, or is removed for misconduct, within three years from the date of his arrival.

All officers of the staff, except principal medical officers, deputy principal medical officers, and sanitary officers, are allowed to take private practice, provided that it does not interfere with the faithful and efficient performance of their official duties, but it is within the power of the Governor to withdraw or suspend the privilege in such places and for such periods as he may consider desirable. It should, however, be noted that private practice does not exist at the majority of stations.

[1] A duty allowance is payable to the holder of the appointment to which it is attached only while he is actually performing its duties, and during his absence or incapacity it is paid, at the discretion of the Governor, to the officer performing them for the time being. A duty allowance is not a pensionable emolument.

OPENING OF THE LONDON MEDICAL SCHOOLS.

WINTER SESSION 1911-12.

St. Bartholomew's Hospital.—The opening of the session will be celebrated by the Old Students' Dinner, which will be held in the Great Hall of the Hospital on Oct. 2nd at 6.30 P.M. for 7 P.M., Mr. W. H. H. Jessop in the chair. Tickets (£1 1*s.*) can be obtained from the honorary secretary, Mr. H. J. Waring, 37, Wimpole-street, London, W., or at the door.

Charing Cross Hospital.—The session will be opened on Oct. 2nd, at 3 P.M., by the annual distribution of prizes to the students in the out-patients' hall of the hospital. The dinner of the past and present students will take place on the evening of the same day.

St. George's Hospital.—The session will begin on Oct. 2nd, at 3 P.M., when Dr. Henry A. Miers, F.R.S., Principal of the University of London, will distribute the prizes and deliver the inaugural oration in the large lecture theatre of the Medical School. The subject of the oration will be "Lucidity." The annual dinner will take place at Princes Restaurant on the same evening, at 6.30 P.M. for 7 P.M. The chair will be occupied by Sir Isambard Owen, consulting physician to the hospital.

Guy's Hospital.—The session will open on Oct. 2nd. The opening meeting of the Hospital Medical School will take the form of a conversazione given by the Pupils' Physical Society, to take place at 8.45 P.M.; all present and past Guy's men are cordially invited to be present. The conversazione will be preceded by a dinner at 7.15 P.M. in the college dining-room. Tickets (price 3*s.* 6*d.*) can be obtained from the honorary secretaries of the Physical Society.

King's College Hospital.—The session will open on Oct. 5th, and the annual dinner will be held on Oct. 2nd, at 6.30 for 7 P.M., at the Waldorf Hotel, Aldwych, W.C., when Dr. Arthur Nicholson will preside. The secretary of the dinner committee is Dr. H. J. M. Playfair, 7, Upper Brook-street, London, W.

London Hospital.—The session will begin on Tuesday, Oct. 3rd, when a reception of old students will be held in the College Library at 3 P.M. Dr. James Mackenzie (the lecturer on Cardiac Research to the College) will deliver the "Schorstein" lecture at 4 P.M. The second lecture will be delivered on Wednesday, Oct. 4th, at the same hour; subject: "Auricular Fibrillation." The old students' dinner will be held at the Hotel Cecil on the Tuesday evening at 7.30 P.M.

St. Mary's Hospital.—The winter session will commence on

Oct. 2nd, when the prizes and awards for the sessions 1910–11 will be presented in the Library at 3 P.M. by the Right Hon. Lord Justice Fletcher Moulton. The annual dinner of past and present students will be held at the Grand Hall, Princes Restaurant, on Oct. 3rd, at 7 P.M., Mr. A. T. Norton, C.B., F.R.C.S., consulting surgeon to the hospital, in the chair.

Middlesex Hospital.—The session will open on Oct. 2nd, at 3 P.M., when Dr. Comyns Berkeley will give an introductory address, after which the prizes gained during the previous year will be distributed by Commendatore Marconi, D.Sc. Oxon., LL.D. The annual dinner of the past and present students and their friends will take place at the Trocadéro on the same evening, at 7 o'clock, when Dr. Frank J. Wethered will preside.

St. Thomas's Hospital Medical School.—The session will be opened on Oct. 3rd by the annual prize-giving. The annual dinner will be held on the same evening at the Hotel Cecil, Mr. G. H. Makins in the chair.

University College Hospital.—The session will be opened on Oct. 2nd, at 3.30 P.M., when the Dean's report on the progress of the medical school will be read, the medals and prizes distributed, and an introductory address delivered by Sir William Ramsay, K.C.B., LL.D., Ph.D., P.R.S. The chair will be occupied by Sir John Rose Bradford, K.C.M.G., F.R.S. The annual old students' dinner will be held on Oct. 2nd, at 7 o'clock, at the Imperial Restaurant, when Sir William Allchin will preside.

Westminster Hospital.—The session will begin on Oct. 2nd, and the annual dinner will take place on Oct. 5th, at the Waldorf Hotel. Dr. Dudley W. Carmalt-Jones, 78, Wimpole-street, London, W., is the secretary of the dinner committee.

London (Royal Free Hospital) School of Medicine for Women.—The session will begin on Oct. 2nd, when Sir Henry Butlin, President of the Royal College of Surgeons of England, will deliver the inaugural address at 4 P.M. Mrs. E. Garrett Anderson, M.D., president of the school, will preside.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

Metropolitan Borough of Paddington.—The decrease of population in most of the metropolitan boroughs, revealed by the preliminary Census report for 1911, will naturally entail considerable revision of mortality statistics. In Paddington the population in 1901 was 143,976. The method adopted in the Public Health Department resulted in an estimate for 1910 of 152,396, or 608 less than the total arrived at by the Registrar-General's formula. The 1911 Census, however, has given a total of 142,576—an actual decrease of 1400 since 1901. On these data the corrected birth-rate for 1910, reckoned at 19·83, becomes 21·18, and the net death-rate 12·58 instead of 11·78. Dr. R. Dudfield gives special prominence to statistics of infantile mortality in the borough. The infant death-rate has continued to fall, and it is claimed that no inconsiderable proportion of the reduction has been due to causes other than the absence of epidemics of infantile diarrhœa during the last five years. This claim is partly based on tabular statements of the mortality of infants in each quarter of the year during the past 20 years, which show that the diminution, though much more conspicuous in the third quarter, is still marked in the first, second, and fourth. In a very instructive appendix on "Mortality of Young Children" Dr. Dudfield has analysed the records of deaths of children under 5 from 1891 to 1910, and presents a series of tables that illustrate the changes which have taken place in the sex and age mortalities during that period, and particularly in the probability of survival of males and females at the end of each year of life up to 5. The latter show that the improvement in the chances of survival has by no means been limited to the infants under one year, but is to be traced also at each succeeding age. Dr. Dudfield refers to the administrative arrangements which result in the general duty of protecting the health of the child passing out of the hands of the sanitary authority, to a large extent, when the child goes to school. In his view "the child should be under the care of the health authority during his school life as he is at other ages, and questions affecting his health should be given the first place, and not be secondary to educational progress as they appear to be now." In regard to notification of births, the report urges an amendment of the law which will do away with the necessity for the present dual system by requiring registration of births by the parent to be effected within five days. Alternatively he would place on the medical officer of health the duty of securing the official registration of the birth after receipt of notification from the parent. Out of 170 deaths certified as due to tuberculosis, 127 were pulmonary. Of these 127 deaths, 57 occurred in institutions, 35 being in Poor-law institutions; 38 of the 127 were deaths of persons who had first been reported to the medical officer of health as suffering from phthisis during the year, while other 37 had been previously so reported. 610 cases of phthisis were brought to the notice of the medical officer of health during 1910 through the tuberculosis dispensary, Poor-law, and other sources; 645 "survivors" were known to the department at the beginning of the year. The action taken in regard to these cases is largely determined by coöperation between the voluntary work of the dispensary and the home visiting by the women inspectors of the council. 1513 persons living in Paddington have presented themselves for treatment or diagnosis at the dispensary during the last two years, of whom 503 were found to present no sign of tuberculosis. The inspection of houses let in lodgings for the purpose of securing cleanliness and compliance with the borough by-laws is an important part of the sanitary work detailed in this report. Out of 17,864 houses in Paddington there are 1320 on the register as let in lodgings. New by-laws were prepared during the year to take advantage of the additional powers in regard to working-class lodgings which have been conferred on local authorities by the Housing and Town Planning Act of 1909. The report has several interesting references to food inspection and adulteration. In connexion with the latter Dr. Dudfield refers to the anomaly that while articles sold as "British wines" may be either non-alcoholic (preserved by salicylates) or alcoholic (17–23 per cent. of proof spirit) no indication of the variety supplied is given to the purchaser. Representations on the subject were made to the Local Government Board.

City of Cardiff.—During Dr. E. Walford's tenure of office the sanitary condition of the city of Cardiff has greatly improved, and its public health organisation has enormously developed. His report for 1910, like its predecessors, illustrates the magnitude and variety of the matters which are dealt with in the sanitary department of a great city. Among these we may refer to the system for the inspection of meat and foods, which is well organised in Cardiff and carried out by a veterinary surgeon and three food inspectors. All the slaughtering in the city is carried on at the municipal slaughter-houses and there is no difficulty in securing an efficient inspection of slaughtered animals. Most of the meat destroyed as unfit for food is surrendered voluntarily by the owner, and the inspectors have directions not to take into court any butcher in possession of tuberculous meat who has notified the fact to the proper authority as soon as he could reasonably be expected to be aware of it. On detection of diseased meat by the inspectors, the butcher or slaughterer is required either to surrender the carcass immediately or to give notice to the chief inspector that he desires the carcass to be detained for further examination. The general system pursued has been arranged between the local butchers' association and the health committee, and the particulars of diseased meat given in the report suggest that it is found satisfactory and efficient in practice. Dr. Walford draws special attention to the condition of bakehouses. He considers that additional powers should be available to require the provision of thermometers, and the fixing of a standard maximum temperature; the provision of flues to ovens and furnaces; a minimum height for the bakehouse; compulsory provision of lavatory accommodation, and of covered metal boxes for bakehouse refuse. These suggestions will receive general endorsement from those who are familiar with the unsatisfactory conditions under which bread is frequently prepared. Rooms have now been fitted at the City Hall for a weekly "consultation of infants," attended by Dr. Elizabeth Elder and the health visitors, which is being very largely used by mothers. Dr. Walford considers that this "consultation" has greatly increased

the practical utility of the Notification of Births Act and the Midwives Act, and that definite medical instruction given on these occasions will yield better results than the alternative of an incomplete system of home visitation by health visitors supplemented by leaflets of instruction. A training centre for midwives has been established at the University College, to which the Cardiff city council and the Glamorgan county council are contributors, with the privilege of nominating women for free studentships. There are 121 certified midwives in Cardiff who probably attended the majority of the 4822 births during 1910. During the year the number of official records of the midwife sending for medical help for the mother was 144—a figure which is small when compared with those in several other large towns. A small outbreak of scarlet fever traceable to a particular milk-supply occurred at the end of the year, but the inquiry made at the suspected farm did not lead to any conclusive evidence being obtained of the occurrence of infection of human origin. It is noteworthy that three deaths occurred among 33 cases, as usually milk-borne scarlet fever exhibits a low fatality rate. Dr. E. Fairfield Thomas contributes to the report a useful account of the municipal tuberculosis dispensary, to which is added a series of charts stated to be good illustrations of the spread of tuberculosis by contact. Without for a moment denying this method of spread, it may be pointed out that by an identical exposition the spread of blue eyes or red hair by contact could be easily shown. And statements, apparently received many years after the event, that infants under two years died from "phthisis" can have very little value as evidence that these children were tuberculous.

County Borough of Swansea.—The misfortune that the introduction of large schemes frequently stops the progress of smaller schemes with the same object has been experienced in Swansea, where a project for the provision of a municipal sanatorium for the treatment of phthisis has been dropped in view of the proposal to erect sanatoriums as part of the Welsh national memorial to King Edward VII.—a project the future of which in its turn is seriously affected by the National Insurance Bill. Dr. D. J. Morgan reports on an additional proposal to provide temporary chalets for phthisical cases, which, however, needed joint action between the town council and the board of guardians and appears to have been found impracticable. Swansea adopted voluntary notification of phthisis during 1910, the fee payable being only 1*s.* From June to the end of the year only 16 notifications were received. Dr. Morgan presses on his authority the need for a bacteriological laboratory under a bacteriologist giving his whole time to the work with suitable assistance, to be established for joint use by the municipal authorities and general hospital, and to be available, without charge, to all local medical practitioners for reports on material submitted, and, if necessary, for original research. Proposals of this kind will probably be made in many places in connexion with the provisions of the National Insurance Bill should these be found to enable local health committees to contribute to bacteriological laboratories, and the officer who has succeeded Dr. Morgan, on the appointment of the latter to the post of medical officer of health of Glamorgan county, may find much advantage from the efforts already made by his predecessor to demonstrate the practical utility of such a proposal. Cerebro-spinal fever was a notifiable disease in Swansea in 1908, when 46 cases were reported. In 1909 there were 12 cases, and in 1910 only 5 cases, all of which, however, were fatal. As another matter of interest may be mentioned Dr. Morgan's efforts to induce the governing bodies of places of divine worship to provide separate drinking-vessels for individual communicants. The single communion cup is now in use in 15 places of worship. In reporting on his work as school medical officer, Dr. Morgan draws attention to observations which have convinced him that the nutrition and physical condition of children derived from the poorest parts of the town are actually better than those of children of the "middle classes" attending the elementary schools. Although they are more dirty, "their bodies are better covered with flesh, their flesh is much firmer, they are more muscular, they are far less anæmic, and they do not exhibit the neurotic or nervous tendency which is so often a characteristic result of our so-called civilisation. ..... The 'middle classes' have to keep up appearances, and this often means a lack of nourishing food."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 8250 births and 6473 deaths were registered during the week ending August 19th. The revised estimate of the population in these towns in the middle of this year is 16,157,797 persons. The annual rate of mortality in these towns, calculated on this revised estimate, which had increased from 11·8 to 18·6 per 1000 in the five preceding weeks, further rose to 20·9 per 1000 in the week under notice. During the first seven weeks of the current quarter the annual death-rate in these towns averaged 15·0 per 1000, while in London during the same period the mean annual death-rate was 14·4 per 1000. The recorded annual death-rates in the 77 towns during the week under notice ranged from 9·6 in King's Norton, 10·5 in Bournemouth, 11·1 in Hornsey and in Hastings, and 12·4 in Bury, to 29·5 in Rhondda, 31·5 in Wigan, 32·6 in Stoke-on-Trent, and 33·4 in Grimsby and in Bolton. The 6473 deaths from all causes during the week in the 77 towns exceeded the number recorded in the previous week by 703, and without exception was the highest number recorded in any week during the current year. These 6473 deaths from all causes included 2720 which were referred to the principal epidemic diseases, against numbers increasing from 268 to 2103 in the seven preceding weeks, and included no fewer than 2553 from infantile diarrhœa, 59 from measles, 46 from whooping-cough, 37 from diphtheria, 14 from scarlet fever, and 11 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases was equal to 8·8 per 1000, against 4·3 and 6·8 in the two preceding weeks. The deaths of infants under two years of age attributed to diarrhœal diseases in the 77 towns, which had increased from 70 to 1927 in the seven preceding weeks, further rose in the week under notice to 2553, and caused the highest annual rates of 15·1 in Stoke-on-Trent, 16·9 in Wigan, 17·0 in Bolton, 17·4 in Aston Manor, and 23·7 in Grimsby. The deaths referred to whooping-cough, which had increased from 43 to 60 in the five preceding weeks, fell again during the week to 46; 14 deaths were registered in London and its suburban districts, 4 in Liverpool, and 3 in Newcastle-on-Tyne. The fatal cases of measles numbered 59, and were 9 above the number returned in the previous week; 17 deaths were recorded in London and its suburban districts, 7 in Liverpool, 5 in Manchester, 4 in Nottingham, and 3 each in Stoke-on-Trent, in Bootle, and in Salford. The deaths from diphtheria, which had fallen from 42 to 24 in the three preceding weeks, rose again to 37 in the week under notice, and included 14 in London and its suburban districts, 3 in Coventry, and 2 each in Preston and in Bradford. The 14 deaths referred to scarlet fever were 9 below the number in the preceding week, and included 2 in London and its suburban districts, and 2 each in Birmingham, Coventry, and Liverpool. The deaths attributed to enteric fever, which had been 11, 8, and 19 in the three preceding weeks, fell to 11 during the week under notice, and included 2 in London and its suburban districts. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily increased from 982 to 1442 in the 18 preceding weeks, fell again to 1388 on Saturday, August 19th; 149 new cases of this disease were admitted to these hospitals during the week, against 209, 191, and 159 in the three previous weeks. These hospitals also contained at the end of the week 772 cases of diphtheria, 247 of whooping-cough, 231 of measles, and 42 of enteric fever, but not one of small-pox. The 1654 deaths from all causes in London during the week under notice showed an increase of 35 upon the number returned in the previous week, and included 97 which were referred to diseases of the respiratory system, against 91 and 90 in the two previous weeks. The deaths attributed to different forms of violence in the 77 towns, which had been 223 and 162 in the two preceding weeks, rose again to 184 in the week under notice, and 373 inquest cases were registered. The causes of 36, or 0·6 per cent., of the deaths registered in the 77 towns during the week under notice were not certified either by a registered medical practitioner or by a

coroner. All the causes of death were duly certified in London, Leeds, Bristol, West Ham, Bradford, Hull, Salford, and in 49 other smaller towns; the 36 uncertified causes of death included 6 in Birmingham, 4 in Liverpool, 3 in Manchester, 3 in Sheffield, and 2 each in Stoke-on-Trent and in St. Helens.

In 77 of the largest English towns 8073 births and 6568 deaths were registered during the week ending August 26th. The revised estimate of population of these towns in the middle of this year is 16,157,797 persons. The annual rate of mortality in these towns, calculated on this revised estimate, which had increased from 11·8 to 20·9 in the six preceding weeks, further rose to 21·2 in the week under notice. During the first eight weeks of the current quarter the annual death-rate in these towns averaged 15·8 per 1000, while in London during the same period the death-rate did not exceed 15·0 per 1000. The recorded annual death-rates in the 77 towns last week ranged from 9·8 in Hornsey, 11·3 in Handsworth (Staffs) and in Halifax, and 11·8 in Reading, to 33·9 in St. Helens, 35·2 in Smethwick, 37 9 in Stoke-on-Trent, and 38·2 in Rotherham. The 6568 deaths from all causes in the 77 towns last week exceeded the number recorded in the previous week by 95, and without exception was the highest number recorded in any week during the current year. The 6568 deaths from all causes included 2900 which were referred to the principal epidemic diseases, against numbers increasing from 268 to 2720 in the eight preceding weeks, and included no fewer than 2714 from infantile diarrhœa, 68 from whooping-cough, 54 from measles, 34 from diphtheria, 12 from scarlet fever, and 18 from enteric fever, and not one from small-pox. The mean annual death-rate from these epidemic diseases was equal to 9·4 per 1000, against 6·8 and 8·8 in the two preceding weeks. The deaths of infants under 2 years of age attributed to diarrhœal diseases in the 77 towns, which had increased from 70 to 2553 in the eight preceding weeks, further rose last week to 2714, and caused the highest annual rates of 15·3 in Bolton and in Hull, 15·8 in Rotherham, 17·6 in Burnley, 17·8 in St. Helens, 18·9 in Stoke-on-Trent, and 20·7 in Rhondda. The deaths referred to whooping-cough, which had been 60 and 46 in the two preceding weeks, rose again last week to 68; 14 deaths were registered in London and its suburban districts, 7 in Liverpool, and 7 in Leeds. The fatal cases of measles numbered 54 and were 5 fewer than the number returned in the preceding week; 13 deaths were recorded in London and its suburban districts, 9 in Liverpool, 7 in Manchester, 4 in Bolton, and 3 in Wolverhampton. The deaths from diphtheria, which had increased from 24 to 37 in the two preceding weeks, fell again to 34 last week, and included 15 in London and its suburban districts, 3 each in Liverpool and in Salford, and 2 each in Newcastle-on-Tyne and Bristol. The 12 deaths referred to scarlet fever were 2 below the number in the preceding week. No death was registered in London or in its suburban districts; 2 of the deaths occurred in Birmingham. The deaths attributed to enteric fever, which had been 8, 19, and 11 in the three preceding weeks, rose to 18 last week, and included 5 in London and its suburban towns, and 3 in Rhondda. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had increased from 982 to 1388 in the 19 preceding weeks, fell again to 1352 on Saturday last; 132 new cases of this disease were admitted to these hospitals during the week, against 191, 159, and 149 in the three previous weeks. These hospitals also contained at the end of last week 746 cases of diphtheria, 242 of whooping-cough, 194 of measles, and 48 of enteric fever, but not 1 of small-pox. The 1646 deaths from all causes in London last week showed a decrease of 6 from the number returned in the previous week, and included 85 which were referred to diseases of the respiratory system, against 90 and 97 in the two previous weeks. The deaths attributed to different forms of violence in the 77 towns, which had been 162 and 184 in the two preceding weeks, fell to 152 last week, and 326 inquest cases were registered. The causes of 39, or 0·6 per cent., of the deaths registered in the 77 towns during the week under notice were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified last week in Bristol, Nottingham, Manchester, Salford, Leeds, Hull, and Newcastle-upon-Tyne, and in 45 other smaller towns. The 39 uncertified causes of death last week included 5 in Liverpool and 4 each in Stoke-on-Trent and in Birmingham.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of this year, 816 births and 465 deaths were registered during the week ending August 19th. The annual rate of mortality in these towns, which had been equal to 13·8 and 14·4 in the two preceding weeks, fell to 14·2 in the week under notice, and was 0·2 below the mean rate in these towns during the first seven weeks of the current quarter, and was 6·7 per 1000 below the mean death-rate during the same period in the 77 large English towns. The annual death-rates in the Scotch towns in the week ranged from 8·7 in Perth and 9·6 in Aberdeen to 16·4 in Glasgow, and 18·7 in Greenock. The 465 deaths from all causes in the eight towns in the week under notice were 6 fewer than the number in the previous week, and included 99 which were referred to the principal epidemic diseases, against 62 and 99 in the two preceding weeks; of these 99 deaths, 78 resulted from diarrhœa, 6 from measles, 7 from whooping-cough, 3 from diphtheria, 4 from scarlet fever, and 1 from enteric fever. The mean annual death-rate from these epidemic diseases in the eight towns in week under notice was equal to 3·0 per 1000, the mean rate in the same period from the same diseases in the 77 English towns having been 8·8. The deaths from diarrhœa, which had been 33 and 70 in the two preceding weeks, further rose during the week to 78, and included 64 of infants under two years of age; 50 deaths occurred in Glasgow, 8 in Greenock, and 6 in Paisley. The 6 deaths referred to measles were 5 below the number in the previous week, and included 4 in Glasgow and 2 in Leith. The 7 fatal cases of whooping-cough were 2 below the number returned in the preceding week, and included 3 in Glasgow and 2 in Edinburgh. The 3 deaths attributed to diphtheria were 2 fewer than the number referred thereto in the preceding week. Of the 4 deaths from scarlet fever 3 were registered in Glasgow, where also the death from enteric fever occurred. The deaths referred to diseases of the respiratory system in the eight towns, which had been 32 and 39 in the two preceding weeks, fell to 29 during the week under notice, and were 9 below the number in the corresponding week of last year. Of the 465 deaths from all causes in the eight towns 129, or 28 per cent., were recorded in public institutions, and 13 were attributed to different forms of violence. The causes of 4, or 0·9 per cent., of the deaths in the eight towns were not specified or not certified; in the 77 English towns the proportion of uncertified causes of death during the week did not exceed 0·6 per cent.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of this year, 815 births and 509 deaths were registered during the week ending August 26th. The annual rate of mortality in these towns, which had been equal to 14·4 and 14·2 in the two preceding weeks, rose to 15·5 last week, and was 1·0 above the mean rate in these towns during the first eight weeks of the current quarter, but was 0·3 per 1000 below the mean death-rate during the same period in the 77 large English towns. The annual death-rates in the Scotch towns last week ranged from 10·2 in Perth and 12·4 in Edinburgh to 16·8 in Dundee and 17·3 in Aberdeen. The 509 deaths from all causes in the eight towns last week were 44 above the number in the previous week and included 114 which were referred to the principal epidemic diseases, against 99 in each of the two previous weeks; of these 114 deaths 88 resulted from diarrhœa, 4 from measles, 12 from whooping-cough, 5 from diphtheria, 4 from enteric fever, and 1 from scarlet fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 3·5 per 1000, the mean rate last week from the same diseases in the 77 English towns having been 9·4. The deaths from diarrhœa, which had been 70 and 78 in the two preceding weeks, rose last week to 88, and included 73 of infants under two years of age; 50 deaths occurred in Glasgow, 16 in Dundee, and 8 in Edinburgh. The 4 deaths referred to measles were 2 fewer than the number in the previous week, and included 3 in Glasgow and 1 in Leith. The 12 fatal cases of whooping-cough were 5

above the number returned in the preceding week, and included 6 in Glasgow and 2 in Edinburgh. The 5 deaths attributed to diphtheria were 2 more than the number in the preceding week; all 5 occurred in Glasgow. The 4 deaths from enteric fever showed an increase of 3 over the preceding number, and included 2 in Glasgow. The deaths referred to diseases of the respiratory system in the eight towns, which had been 39 and 29 in the two preceding weeks, rose to 41 last week, and were 8 below the number in the corresponding week of last year. Of the 509 deaths from all causes in the eight towns last week 157, or 31 per cent., were recorded in public institutions, and 27 were attributed to different forms of violence. The causes of 14, or 2·8 per cent., of the deaths in the eight towns last week were not specified or not certified; in the 77 English towns the proportion of uncertified causes of death during the week did not exceed 0·6 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 614 births and 427 deaths were registered during the week ending August 19th. The annual rate of mortality in these towns, which had been 16·4, 16·8, and 17·1 in the three preceding weeks, rose to 19·4 per 1000 in the week under notice. During the first seven weeks of the current quarter the annual death-rate in these towns averaged 16·8, whilst the mean rate during the same period did not exceed 15·0 per 1000 in the 77 English towns, and was equal to 14·4 in the eight Scotch towns. The annual death-rates in the week under notice was equal to 25·1 in Dublin (against 19·1 in London), 18·8 in Belfast, 12·9 in Cork, 16·6 in Londonderry, 10·9 in Limerick, and 22·8 in Waterford; whilst in the 16 smallest of these Irish towns the mean annual death-rate did not exceed 12·4 per 1000. The 427 deaths from all causes in the 22 Irish towns during the week under notice showed an increase of 50 over the number returned in the previous week, and included 114 which were referred to the principal epidemic diseases, against 83 and 117 in the two preceding weeks; of these 114 deaths, 104 resulted from diarrhœal diseases, 3 from enteric fever, 3 from whooping-cough, 3 from diphtheria, and 1 from measles, but not any from small-pox or scarlet fever. The 114 deaths from the principal epidemic diseases were equal to an annual death-rate of 5·2 per 1000; the mean rate from the same diseases in the 77 English towns was equal to 8·8 per 1000, whilst in the eight Scotch towns it was 3·0. The deaths attributed to diarrhœal diseases, which had been 66 and 106 in the two preceding weeks, fell to 104 in the week under notice and included 93 of infants under two years of age; 56 deaths were registered in Dublin, 30 in Belfast, and 3 each in Cork, Londonderry, Waterford, and Portadown. The 3 deaths from whooping-cough were 1 in excess of the number in the previous week, and were all registered in Dublin. Of the 3 deaths from enteric fever, 2 occurred in Dublin and 1 in Belfast. The deaths from diphtheria occurred in Dublin, Belfast, and Dundalk, and the death from measles occurred in Newtownards. The deaths referred to diseases of the respiratory system in the 22 towns, which had been 20 and 38 in the two preceding weeks, rose during the week under notice to 39. Of the 427 deaths from all causes in the 22 town districts 123, or 29 per cent., occurred in public institutions, and 16 deaths were attributed to different forms of violence. The causes of 14, or 3·3 per cent., of the deaths registered in the 22 towns were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes of death during the week under notice did not exceed 0·6 per cent. in the 77 large English towns, and was equal to 0·9 in the eight Scotch towns.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 623 births and 426 deaths were registered during the week ending August 26th. The annual rate of mortality in these towns, which had been 16·8, 17·1, and 19·4 in the three preceding weeks, fell to 19·3 per 1000 in the week under notice. During the first eight weeks of the current quarter the annual death-rate in these towns averaged 17·1, whilst the mean rate during the same period was 15·8 per 1000 in the 77 English towns, and was equal to 14·5 in the eight Scotch towns. The annual death-rate last week was equal to 20·1 in Dublin (against 19·0 in London), 29·7 in Belfast, 25·9 in Cork, 25·6 in Londonderry, 17·7 in Limerick, and 32·3 in Waterford; whilst in the 16 smallest of these towns the mean annual death-rate was 21·6 per 1000. The 426 deaths from all causes in the 22 Irish towns showed a decline of 1 from the number returned in the previous week and, included 133 which were referred to the principal epidemic diseases, against 117 and 114 in the two preceding weeks; of these 133 deaths, 112 resulted from diarrhœal diseases, 8 from whooping-cough, 5 from diphtheria, 4 from enteric fever, 3 from measles, and 1 from scarlet fever, but not any from small-pox. These 133 deaths from the principal epidemic diseases were equal to an annual death-rate of 6·1 per 1000. The mean rate from the same diseases in the 77 English towns was equal to 9·4 per 1000, while in the eight Scotch towns it was 3·5. The deaths attributed to diarrhœal diseases, which had been 106 and 104 in the two preceding weeks, rose to 112 last week, and included 93 of infants under two years of age. Forty-eight deaths were registered in Dublin, 33 in Belfast, 7 in Newtownards, 6 in Cork, and 5 in Limerick. The 8 deaths from whooping-cough showed an increase of 5, and included 6 in Dublin. The 5 deaths from diphtheria were 2 more than the preceding number, and were all registered in Dublin. The 4 deaths from enteric fever showed an increase of 1, and included 2 in Belfast. The 3 deaths from measles were 2 more than the number recorded in the preceding week, and included 2 in Newtownards. The deaths referred to diseases of the respiratory system in the 22 towns, which had been 38 and 39 in the two preceding weeks, fell last week to 30. Of the 426 deaths from all causes in the 22 town districts last week, 111, or 24 per cent., occurred in public institutions, and 11 deaths were attributed to different forms of violence. The causes of 16, or 3·8 per cent., of the deaths in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified deaths during the week under notice did not exceed 0·6 per cent. in the 77 large English towns, and was equal to 2·8 per cent. in the eight Scotch towns.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Surgeon George Oswald Morrell Dickenson has been promoted to the rank of Staff-Surgeon.

The following appointments are announced:—Staff-Surgeons: P. T. Sutcliffe to the *Pembroke*, additional, for the *Falmouth*, and to the *Falmouth*, on commissioning; W. E. Gribbell to the *Defiance*; F. E. Anly to the *Sappho* for voyage out to Port Said and to the *Philomel* on recommissioning. Surgeons: A. D. C. Cummins and G. Carlisle to the *Victory*, additional, for disposal; L. C. Rowan-Robinson to Gibraltar Hospital; A. S. Bradley to the *Excellent*, additional, for the *Grafton*; A. C. W. Newport to the *Royal Arthur*.

ROYAL ARMY MEDICAL CORPS.

The name of Major Langford N. LLoyd, D S.O., is as now described, and not as stated in the Gazette of August 4th, 1911.

Lieutenant-Colonel Samuel R. Wills retires on retired pay (dated August 30th, 1911).

The undermentioned Lieutenants to be Captains (dated August 4th, 1911):—John James, Alfred C. H. Suhr, John E. Ellcome, Gerald J. Keane, Harold H. Blake, Robert M. Dickson, Frank Worthington, Frederick H. Bradley, Alexander L. Stevenson, Bernard Varvill, Joseph W. Houston, Arthur Shepherd, Wilfred J. Dunn, Frank B. Dalgliesh, Malcolm Leckie, Spencer G. Walker, Charles E. L. Harding, Falkiner M. Hewson, Arthur L. Foster, Claude M. Rigby, Alan G. Wells Alexander E. G. Fraser, Walter H S. Burney, Thomas S Eves, Leo Murphy, Arthur H. T. Davis, John S. McCombe, William J. Tobin, Campbell McQueen, and Robert O'Kelly.

The undermentioned to be Lieutenants (on probation) (dated July 28th, 1911):—Basil Hamilton Hebden Spence, William Balfour Laird, Douglas Walter Bruce, Herbert Stuart Blackmore, Edward Spencer Calthrop, Leonard Buckley, Lieutenant Francis Robert Bradley Skrimshire (from the 4th Battalion, The Hampshire Regiment), Richard Trevor Vivian, Thomas Edward Osmond, Ernest Cotton

Deane, Stanley Parkinson Sykes, Robert Davidson, Edward George Huxley Cowen, Edward Bruce Allnutt, James May Elliott, Harry Campbell Todd, Maurice Drummond, Alexander Gillilan Johnson MacIlwaine, William Stewart, Frank Stuart Tamplin, Ivor Robert Hudleston, Arthur Stanley Heale, Arthur John Ormsby Wigmore, Henry James Gordon Wells, and Lieutenant William Leckie Webster (from the Royal Army Medical Corps, Special Reserve).

The under-mentioned Lieutenants (on probation) are seconded under the provisions of Article 300, Royal Warrant for Pay and Promotion, 1909 (dated July 28th, 1911): William B. Laird, Francis R. B. Skrimshire, Thomas E. Osmond, Edward B. Allnutt, and Harry C. Todd.

Lieutenant-Colonel H. L. Battersby has been appointed to medical charge at Ipswich. Lieutenant-Colonel T. W. O'H. Hamilton, C.M.G., is retiring on half-pay. Major J. S. Gallie has joined for duty in the London District. Major T. H. J. C. Goodwin has been granted four months' leave. Captain G. Petit has been granted three months' leave. Captain T. W. Browne and Captain C. Kelly have been granted extensions of leave. Lieutenant-Colonel L. T. M. Nash, commanding the Station Hospital at Karachi, has arrived home on leave of absence. Major F. W. Begbie, surgical specialist at Colchester, has been appointed Commandant of the Royal Army Medical Corps Camp of Instruction at Tidworth Park, Salisbury Plain. Major G. B. Carter, from the Curragh Camp, Kildare, has taken over charge of the Military Hospital at Rangoon. Major H. B. G. Walton has been transferred from Bareilly Cantonment to the Station Hospital at Mussoorie. Captain J. H. Duguid, from Limerick, has taken up duty at Tipperary. Captain H. V. Bagshaw has been transferred from Halifax to Lichfield for duty at the Military Hospital. Captain A. C. Osburn, on completion of duty at the Military Hospital, Bedford, has been posted to Colchester. Captain M. O. Wilson, from Ambala Cantonment, has been appointed to Gharial. Captain E. W. Siberry has arrived home on leave of absence from South Africa. The following officers, on completion of their course of instruction at the Royal Army Medical College, London, have been posted for duty to the Eastern Command: Captains A. E. B. Wood, J. B. Meldon, J. M. M Crawford, C. Bramhall, T. S. Dudding, R. H. MacNicol, W. Waley, M. D. Ahern, and C. J. Wyatt. Lieutenant M. J. Williamson, from Cardiff, has been appointed to Tidworth, Salisbury Plain. Lieutenant O. W. McSheehy has been transferred from Exeter to Devonport. Lieutenant A. T. J. McCreery, on completion of a course of instruction in Indian sanitation at Poona, has been appointed to the Station Hospital at Khandalla. Lieutenant C. H. O'Rorke, from Lucknow, has joined the Station Hospital at Chakrata.

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions:—To be Colonel: Lieutenant-Colonel John Smyth (dated June 7th, 1911). To be Captains: Lieutenants James William Barnett and Madan Lal Puri (dated March 8th, 1911).

The King has also approved of the retirement of Lieutenant-Colonel Alexander Milne (dated July 25th, 1911).

Lieutenant-Colonel E. H. Wright has been selected to officiate as Principal of the Madras Medical College. Major T. H. Foulkes has been granted leave of absence home from India for one year. Major E. M. Illington has taken up duty at Waltair as district medical and sanitary officer of Vizagapatam. The services of Major P. P. Atal have been placed at the disposal of His Excellency the Commander-in-Chief by the Government of India. Major R. H. Elliot has arrived home from India on six months' combined leave of absence. Captain W. A. Justice has been appointed to officiate as Sanitary Commissioner of Madras Presidency during the absence on deputation of Lieutenant-Colonel H. Thompson. Captain C. A. F. Hingston has taken up duty as Ophthalmic Surgeon at the Medical College Hospital, Madras, during the absence on leave of Major R. H. Elliot. Captain M. F. Reaney has been appointed a Civil Surgeon of the Second Class by the Government of India. Captain T. G. N. Stokes, sanitary commissioner of the Central Provinces, has been granted six months' leave of absence home from India. The services of Captain F. C. Fraser have been replaced at the disposal of His Excellency the Commander-in-Chief by the Government of India. Captain E. O. Thurston has been appointed to officiate as Professor of Anatomy at the Medical College, Calcutta, and Surgeon to the College Hospital during the absence on leave of Major C. R. Stevens. Captain J. W. H. Babington has been granted general leave for one year. Captain G. S. Husband has been appointed to the medical charge of the 9th Bhopal Infantry at Fyzabad. Captain F. H. Stewart has been appointed to the medical charge of the 74th Punjabis at Lucknow. Captain H. C. Buckley has been detailed for plague duty in the Punjab. Captain C. H. Fielding has been appointed to the medical charge of the 17th Infantry at Manipore. Lieutenant K. K. Mukerji has been permanently transferred to Kohat.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant James O. Hamilton is confirmed in his rank.

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd Northumbrian Field Ambulance: To be Captains: Lieutenant D. V. Haig (dated July 30th), Lieutenant D. L. Fisher (dated July 31st), and Lieutenant G. G. Farquhar (dated August 1st).

1st Northern General Hospital: Captain W. E. M. Ede resigns his commission (dated August 19th).

Attached to Units other than Medical Units.—Captain G. Wilson to be Major (dated May 1st), and Captain A. Hilton to be Major (dated July 12th).

For Attachment to Units other than Medical Units.—S. L. Brimblecombe to be Lieutenant (dated May 11th), and Lieutenant P. Moxey, from 3rd South Midland Field Ambulance, to be Lieutenant (dated August 21st).

DEATHS IN THE SERVICES.

Deputy Surgeon-General John Jones, formerly of the Indian Medical Service, on August 8th, at his residence, 231, Cromwell-road, London, S.W., aged 81 years. He obtained the qualification of M.R.C.S. Eng. in 1853 and that of M.R.C.P. Lond. in 1860; he also graduated as M.D. at the University of St. Andrews in 1856. He entered the Bengal Medical Service as assistant surgeon on Feb. 20th, 1856, and a year later served during the Indian Mutiny with the Delhi Field Force after the capture of Delhi, taking part in the actions of Narnoul and Karkarala, the capture of Bareilly, the operations in Oude, and the action of Mehndee (medal). He was promoted surgeon on Feb. 20th, 1868; surgeon-major on July 1st, 1873; brigade surgeon on April 1st, 1882; and retired with the rank of deputy surgeon-general on Jan. 17th, 1885. He was for some time surgeon superintendent of the Bengal Presidency General Hospital.

Deputy Surgeon-General Robert Walter Clifton, formerly of the Army Medical Staff, on August 16th, at 15, Auriol-road, West Kensington, London, W., aged 75 years. He became qualified as M.R.C.S. Eng. in 1857, and joined the army as assistant surgeon in September of the same year. In 1860–61 he served in the China war, and was present at the action of Sinho and the capture of the Taku Forts (medal with clasp). He was promoted to surgeon on August 31st, 1872; to surgeon-major on March 1st, 1873; to brigade surgeon on Jan. 2nd, 1883; to deputy surgeon-general on June 21st, 1887; and retired with the rank of deputy surgeon-general on April 11th, 1889. During the latter period of his service he was principal medical officer of the Curragh Brigade.

Lieutenant-Colonel James Scanlan, formerly of the Army Medical Staff, on August 12th, at Kerswell, Broadclyst, Devon, aged 64 years. He studied medicine at the University of Glasgow, where he graduated as M.B. and C.M. in 1868. Entering the army in October of that year he was promoted surgeon in March, 1873, and surgeon-major in October, 1880, retiring with the rank of lieutenant-colonel in October, 1888. He served in India and also in the South African war in 1881.

EXETER CITY ASYLUM.—At the last meeting of the Exeter city council it was reported that for the year ended March 31st last the city asylum had been so managed that its working expenses were all paid, and a sum of £1203 had been placed towards the interest and sinking fund.

"Audi alteram partem."

A QUESTION IN EUGENICS.

To the Editor of THE LANCET.

SIR,—Since you invite an expression of opinion upon this subject from the profession at large permit me to signify my unqualified endorsement of the sensible and humane position assumed by Dr. Robert Jones in THE LANCET of August 12th, p. 472. The problem of the survival of the unfit is one the gravity of which increases *pari passu* with the advances of civilisation. In more primitive communities the unfit individual tends to be eliminated by the rigour of the conditions of existence; under milder conditions of upbringing he survives to the detriment of the race. From the point of view of physical and moral hardihood there can be little doubt that it is possible to over-civilise and to render the conditions of life too easy.

Since the degenerate has increased and is increasing, how, then, are we to deal with him so as to put some curb upon his further multiplication? Are we to revert to more Spartan conditions of upbringing and so let Nature solve the problem for us? Are we to promote the euthanasia of the hopelessly unfit? Are we so to mutilate them as to render them incapable of propagating their unfitness? Or are we to deal with them as we do at present, trusting that the gradual amelioration of the race may by-and-by reduce their proportion? The full discussion of these problems would require not a letter but a volume. There is much to be said for the first and fourth propositions, and, startling as it may sound, even something for the second, more particularly in the case of the graver forms of idiocy. It is generally recognised that the State has the right to kill, but it is repugnant to every instinct of common justice and humanity to maintain that it has the right to mutilate. The degenerate child did not ask to be born. He is a responsibility and an encumbrance, and may possibly be a danger, but that is no reason why, of a man, we should make him nothing. Life under such conditions is not worth living. Better, far better, a merciful death than so hideous a fate.

Few physiologists will deny that there is an inseparable and deep-rooted connexion between the integrity of the generative functions and those of the mind. Alike mentally and physically, the eunuch is lazy, apathetic, and nerveless. Should he develop activities they are for the most part monstrous and abnormal. He is outside the pale of humanity; and the knowledge that he is not as other men so reacts upon his nature as to render him inhuman. Overpowered by despair and by the ever-present sense of degradation, he is either goaded into madness with Attis, or into fiendish atrocities with the diabolical Agha Muhammad. More commonly, however, he sinks into that condition of nullity which is the doom of the vast majority of his miserable brotherhood. The exceptions of Narses and Origen serve merely to emphasise the rule. And so also with minor degrees of sexual imperfection, such as those produced by vasectomy. I recall the case of a cryptorchid, which may serve as an illustration. The man was not impotent, though his sexual appetite was of the smallest. He belonged to the educated classes, but was one of the most unintellectual of mankind. He shunned general society; was a wretched conversationalist; read nothing except the newspaper; and was seemingly incapable of responding to any mental stimuli higher than those of present need or prospective amusement. He was entirely self-centred, lukewarm in his affections, without consideration for others, neglectful of business, and destitute of any serious object in life.

The madman in his lucid intervals, and the epileptic in the intervals of his epilepsy, may be persons of sound sense, or possibly even of genius. To take the first instances that occur to me, the poet Cowper and Charles and Mary Lamb were all subject to attacks of mental derangement. Once admit the principle of sterilisation for mental disease, and I echo the pertinent query of Dr. Robert Jones, Where are you going to draw the line? Had these persons been sterilised when they first showed signs of insanity they would almost certainly have been reduced to the average level of intelligence, if not beneath it. As none of them married or had issue posterity would have been none the better; but who shall dare to say that literature would have been none the worse? Before mutilating a child or an adolescent at the instance of some crack-brained exponent of eugenics, it might be well to pause and consider whether we are not abolishing a possible genius. It might be well also to remember that England is neither in Switzerland nor in Indiana, and that her system of jurisprudence differs somewhat from that of those enlightened quarters of the globe.

From the point of view of professional ethics I cannot too strongly express my opinion that all operations whose sole aim and object is the production of sterility are utterly indefensible. It is the duty of the practitioner to do that which is best for his patient individually, not that which is worst for his patient, even though it be supposed by some to be for the advantage of the race. The case of the degenerate is pitiable enough already. What right has he to render it more so? It is his duty to remember alike what is due to his patient and to himself. The surgeon is supposed to be a gentleman—a man not merely of humanity but of culture and refinement; and he owes it to himself so to support that character that the public may recognise and respect it. Surely it is nothing short of an insult to propose to such an one that he should degrade himself to the level of a sow-gelder or a Chinese knifer!

I am, Sir, yours faithfully,

BRYAN CHARLES WALLER, M.D., F.R.C.S. Edin.,
Sometime Lecturer on Pathology in the School of Medicine, Edinburgh.

Kirkby Lonsdale, August 15th, 1911.

To the Editor of THE LANCET.

SIR,—In my opinion the letters of Dr. Robert Jones and Dr. C. T. Ewart in THE LANCET of August 12th clearly and ably placed before your readers the two sides of the question whether a father who has an epileptic son has the right to have him sterilised to prevent the propagation of the epileptiform species, and would a surgeon be morally and legally justified in doing the operation. To my mind the question is purely a moral one, and its answer will solely depend upon the moral standard of the father and the surgeon, as well as the moral standard of the State to whose laws they are both subject. Hence, it will no doubt interest your readers if I state my views on the question raised as a father and a physician and surgeon who is a member of the Catholic Church.

If I had an epileptic son I would not as a Catholic have him sterilised to prevent the reproduction of epileptiform offspring. I cannot at present point to any specific Catholic dogma on the subject, for I presume the question has not been discussed by Catholic theologians, but I base my opinion on the spirit and letter of Catholic teaching in the following analogous case. If a Catholic husband should ask his spiritual adviser if he would be justified in using artificial means to prevent conception because his wife was in delicate health and she had been told by her medical attendant that if she had a child it might not survive its birth, or if it did survive it would be an unfit on account of inherited weakness either of disease or of constitution and would not live long, or were its life prolonged it would be a burden to the parents and to the State; the answer of the spiritual adviser would be that under no circumstances whatever, not even to prevent the reproduction of the unfit, was it lawful to use artificial means to prevent the propagation of the human race. The husband and wife would be counselled to practise continence until a healthy child could be born, and if the conditions were such that the birth of a healthy child was an impossibility, then they could either be always continent or bear the burden of a weak offspring, the former course being the one that they would be advised to adopt. From this answer it can be logically argued that a Catholic father would not be morally justified in having his epileptic son sterilised to prevent the reproduction of degenerate species. The course that the Catholic father would adopt would be to use every possible moral means to prevent his epileptic son from marrying, and the father's efforts in this direction would be earnestly and strenuously supported by the son's spiritual adviser. It will also be evident from the answer that a Catholic surgeon would

not be justified in doing the operation, just as no Catholic physician or surgeon is justified in conniving at the practice of race-suicide by telling a patient, who may consult him on the subject, how the thing is done.

From the point of view of a sociologist it seems to me that the crux of the question raised lies in the pertinent query of Dr. Robert Jones: What is to be the limit of sterilisation to prevent the reproduction of the unfit? If we sterilise to prevent the propagation of epilepsy and thus improve the race, why not sterilise to prevent the reproduction of the mentally degenerate and the physically defective, the child with inborn tendencies to all forms of wickedness and criminality, and the child with inherited weakness whether of disease or of constitution? I am afraid that if this were done we would have to sterilise the major part of the human race. Then who would be the final arbiter in sterilisation, and would the father, when it was found that one child was unfit, submit himself to be sterilised to prevent more unfits? It is to be noted that Dr. Ewart, either unwittingly or wittingly, did not allude to this vital point of the limitation of sterilisation.

There is just one other point I would wish to place before your readers, and it was no doubt in the mind of Dr. Robert Jones when he wrote that sterilisation would not possibly improve the moral and mental qualities of the race, for the presence of human weakness was a moral appeal to the strong and served a useful purpose in the moral development of any people. While I am aware of the difference between the prevention by physical means of the birth of the unfit for the good of the race and the destruction of the unfit by the same means and for the same object, there is a dangerously narrow border-line between the two, and transition from the one act to the other would be easy. The arguments that could be urged for the one act could be urged with equal logic and force for the other. To destroy the unfit for the physical good of the race would be a complete reversal of the hands of the clock of civilisation, for it would reduce man to the ethical level of the brute. In my opinion, the lion or the tiger, which seems to have no control over its vicious impulses and devours weaker animals for its own preservation and for the joys and pleasures of its life, would have as high an ethical standard as that of the man who would destroy the unfit for what would be practically his own ease and comfort, and to avoid the practice of self-denial and the control of his inherent selfish and lustful desires for the satiations of a luxurious life. As a matter of fact, the ethics of the brute would be higher than those of man, for in its case the question of self-preservation is involved in its destruction of weaker animals, and the brute does not kill or even acquiesce in the destruction of its own unfit, but, on the contrary, it will guard and protect its young, whether fit or unfit, even to the point of sacrificing its own life.

I cannot conclude without thanking Dr. Robert Jones for his luminous and closely reasoned letter. The value of his opinion lies in the fact that it is the opinion of a distinguished alienist whose sound judgment is based on mature experience in the observation and treatment of mental disease. His opinion on this question is, I am quite sure, the opinion of every Christian father and every Christian physician and surgeon in the civilised world.

I am, Sir, yours faithfully,

THOMAS COLVIN, M.D., M.S. Glasg., J.P.

Glasgow, August 25th, 1911.

THE CURIOUS HISTORY OF A SWALLOWED PIN.

To the Editor of THE LANCET.

SIR,—I was much interested in reading the case related by Dr. Wilfred Balgarnie in THE LANCET of August 19th, p. 500, under the above title. It reminded me of a somewhat similar circumstance which occurred during my practice in Paris towards 1862 or 1863, and I fancy that, being at that time your "own correspondent," I may have referred to it in one of my weekly letters.

In the Rue de Matignon, Faubourg St. Honoré, where I lived, I had a neighbour, a Hungarian, who was a working glover. One morning the glover's wife brought into my consulting-room a screaming baby boy of the crawling age—i.e., 18 months old. The mother, evidently in great anxiety, told me that whenever moved or carried about the poor baby began screaming until again replaced in its cradle. On the child being stripped I found it well nourished and undisturbed by palpation, excepting in one spot a little below the sternum. Here very slight pressure on one particular point induced a fit of screeching which indicated a definite localised trouble. On passing the finger very gently over the tender place I distinctly felt a point which was slightly movable and which was evidently the source of the pain. I at once made a slight incision through the integuments, when to my surprise a little black point protruded from the wound. This, with a pair of small forceps, I drew out very gently, and to my astonishment I withdrew a small bundle of about 2 inches long, quite black, which I ascertained to be a needle wrapped up in thread. This was at once recognised by the mother as a glover's needle which the child must have swallowed while crawling about the floor, and which had worked its way outwards through the coats of the stomach. The operation over, the child fell fast asleep and recovered in two or three days after parting with this dangerous encumbrance. My wife, who had taken possession of the child during the operation, perfectly remembers this incident which occurred about 50 years ago.

I am, Sir, yours faithfully,

Worthing, August 20th, 1911. I. D. CHEPMELL.

*** We do not see any reference to the episode in Dr. Chepmell's interesting letters while he was our valued correspondent in Paris. Dr. Balgarnie writes that the scar at the great curvature of the stomach was situated 1½ in. from the pylorus, and not 4½ in., as printed.—ED. L.

SOME POINTS IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—Whilst enclosing a copy of my annual report, I should like to observe that the perplexities connected with the treatment of pulmonary tuberculosis seem to increase as the years roll on. Personally, I am inclined to think that there are so many differences of opinion amongst authorities because a large number of persons who treat this disease take no precautions to discover whether the disease is active or not. The only method of which I am aware for ascertaining whether the disease is still active or not is to take the rectal temperature before rising in the morning, and if it is not as low as 36·5° C. (97·7° F.) assume that the morbid processes are still progressing; in arriving at an estimate of the patient's condition very little attention should be given to the patient's remarks about improvement or otherwise, for, as a rule, when the disease is easily curable the subjective symptoms are not marked. From a careful study of the previous histories of these cases I have been forced to the conclusion that chronic fibroid phthisis is the product of exercise taken at a period when the temperature is slightly raised—that is to say, when the products of the tubercle bacillus are of low virulence. If the fever be greater than this, the subjective symptoms will also be considerable, and night sweats will usually be occurring; if exercise be persisted in, a chronic fibroid phthisis will not, as a rule, be produced, but a large amount of caseous material; these cases may either proceed to a galloping consumption, or the disease may become arrested, leaving the patient in a crippled condition, the amount of crippling being directly proportionate to the antecedent damage. Fibroid destruction of a lung, following upon pleurisy, would seem to be due to an irritant of low virulence acting over a long period. Now if it be granted that all so-called idiopathic pleurisies are tubercular, it is not fair to assume that all cases of pleurisy will develop into what is generally understood by the term pulmonary tuberculosis. I suppose a very large number of these cases go on to complete and natural cure. I would suggest, however, in cases of pleurisy of this kind, that the patients be kept in bed until their temperatures reach 36·5° C. (97·7° F.) before rising in the morning. This method would, I am sure, prevent the development of a large number of serious cases. Of course in the event of such treatment not being successful, recourse might then be made to tuberculin

or sanatorium treatment—or both—as the judgment of the practitioner might decide.

Compared with the temperature taken before rising, temperatures taken at other times in the day are comparatively unimportant. The first thing to be done, therefore, in treating a case suspected to be suffering from pulmonary tuberculosis, is to put the patient in bed and then find out the rectal temperature before rising in the morning. In April, 1909, I published an article on "Graduated Rest in the Treatment of Pulmonary Tuberculosis," in which I advocated the strict resting and seclusion of all early cases. I was not then referring to what are ordinarily understood by febrile cases, which have been rested in all properly conducted sanatoriums since the days of Dettweiler. The treatment by means of the production of an artificial pneumothorax all tends in the same direction, though I imagine that when possible it will be preferable for patients to lie quietly in bed, apart from their relatives, for a week or ten days, to, at some later period, going to the risk and trouble of an artificial pneumothorax, which may have to be kept in operation for a period of years.

I am afraid that at the present time there is a good deal of indiscriminate administration of tuberculin, and this is often done without taking a rectal temperature before rising in the morning. If such a temperature were taken the variations noted would surprise a good many who administer tuberculin without this precaution. I may say, in passing, that after very considerable experience I have never known a case of pulmonary tuberculosis do really well in which the rectal temperature before rising did not approximate to 36·5° C. (97·7° F.). Of course, I am quite aware that a considerable number of patients who have a temperature of this kind are by no means cured; these are, as a rule, chronic cases in which the disease has existed for some considerable time (often for years).

Furthermore, there is always some disadvantage in treating patients with the hair of the dog that bit them, insomuch that if benefit follows reactions after suitable doses, how long are we to continue giving these patients a little more of the disease, and how far are we justified in working up the disease to fresh activity? Latterly I have been administering tuberculin in such doses that no reaction is produced except, perhaps, at the seat of injection. As time only will show what effect this method will produce, I am unable to state further than that in some cases the appetite is improved and there is a more progressive gain in weight. I have no doubt that in the majority of us, any tubercle we may acquire is not ordinarily cured by means of a violent reaction. I have seen great benefit follow violent reactions due both to tuberculin and to the natural disease. Unfortunately, in both cases I have more often seen harm follow.

I have tried giving continuous inhalations of carbolic acid, but so far I have not been able to obtain the results sometimes claimed for this method of treatment. So far as I can gather, the first lot of successful cases published by Dr. Lees referred to early cases and not mixed infections; latterly I have noticed that this method has been claimed as being specially useful in mixed infections. I have seen very little evidence of this, but have found that a respirator worn without any drug being used produces benefit when cold east and north-east winds have caused irritation of the air-passages; in this case the inhaler acts as an extra piece of trachea or of mouth, as the case may be. Really incipient cases generally tend to improve markedly if they cease from their employment only.

I put forward tentatively the following propositions in the hope that they may be of assistance to others, who, like myself, are daily worried by the numerous cures put forward both by the profession and by the lay public. 1. That everyone in an industrial community, by the time he reaches 20 years, has suffered from tuberculosis. 2. That the majority of persons get well without symptoms—that is, without reactions. 3. That a proportion get well after well-marked symptoms—that is, after pronounced reactions. 4. That, relative to the whole number of cases, a few of the patients recover after being looked upon as hopeless. The enormous number of actual cases of this disease accounts for so many of this class of case cropping up. 5. That in early cases it is usually impossible to tell when activity has ceased unless a rectal temperature be taken before rising. 6. That the disease tends to cure itself. Upon this factor is founded the rationale of treatment by tuberculin. 7. That in treating tuberculosis of the lung the effect on surgical tuberculosis of tuberculin must not be too much given in evidence. 8. That from the onset of hæmoptysis or pleurisy years may elapse, during which time the patient may walk about either in perfect health or in apparent perfect health.

Early cases of pulmonary tuberculosis may be benefited by the judicious use of tuberculin, and many advanced cases may perhaps be prevented from occurring, but if the duration of the disease before many patients at present elect to come to a sanatorium be considered it will appear that a very considerable number of years must elapse before the precise value of this treatment can be ascertained. One thing, however, seems to me quite clear, and that is that no treatment can be considered as worth while which does not tend to produce a temperature of 36·5° C. (97·7° F.) before rising in the morning.

Finally, as a warning, I would remark that the restoration to permanent working capacity of patients of the kind that at present come to this sanatorium, using every method of treatment that has been suggested, is very difficult.

I am, Sir, yours faithfully,

EDWARD E. PREST.

Ayrshire Sanatorium, New Cumnock, August 21st, 1911.

THE SCIENTIFIC PRINCIPLES OF INHALATION.

To the Editor of THE LANCET.

SIR,—In the LANCET of May 21st, 1892, the Scientific Principles of Inhalation were submitted to your readers, and the state of knowledge on that subject was fairly considered. Dr. Baxter, in his report as medical officer of the Privy Council, had stated that "it was well-nigh impossible to obtain an atmosphere containing a given percentage of the vapour," and it seemed from his experiments upon the action of certain disinfectants on vaccine lymph that practically no effect was obtained by them in their action as vapours. As it seems probable that some attention is going to be given to this subject I venture to refer to the communication you were so good as to publish in THE LANCET nearly 20 years ago. The observations made by Dr. Piesse and Mr. Johnston were published in the *Medical Press and Circular* on June 11th, 1885. When I directed the attention of the late Sir Richard Quain to the very unsatisfactory class of agents described in the British Pharmacopœia under the general title of "Vapores" he decided that they must be excluded from the new edition which was near publication. Let us hope that the time has come when the therapeutic value of vapours when properly prepared and administered is going to be studied and turned to use in the treatment of a large class of maladies.

I am, Sir, yours faithfully,

August 25th, 1911. ROBERT LEE.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Death-rate and the Strikes.

THE deplorable state of affairs consequent on the strike, with the practical cessation of nearly all work for more than a fortnight, led to a considerable increase in the death-rate of the city, as reported at the meeting of the health committee held on August 24th. Owing to the strike of the corporation scavengers, the dirty condition of the streets and the accumulation of refuse from the ash-pits and middens became a public danger. The death-rate of the city for the preceding week was 27·1 per 1000, as compared with 16·5 per 1000 in the corresponding week of last year. Of 390 deaths, zymotic diseases claimed 285 victims, of whom 191 were under 12 months. The deaths in the corresponding week of last year from infantile diarrhœa were 27, as compared with 157 last week. Probably the hot summer with its prolonged drought was responsible in a measure for a proportion of this high death rate. The medical officer of health, in reply to the question of how Liverpool compared with other cities in England where strikes had occurred, replied that there was a very wide range in the death-rate, but he was afraid that the

greatest injury had been done where strikes and labour disturbances prevailed. The carriage of sterilised milk supplied by the corporation for the use of infants of the poorer class had been seriously interfered with. The city presented the appearance of a besieged city with its barricaded shop windows. This precaution was adopted as many shops, especially in the lower parts of the city, were looted by the hooliganism which disgraced the city. The strikers are acquitted of taking part in this ruffianly conduct.

English Cholera in Mid-Cheshire.

The Northwich urban and rural areas are suffering from an epidemic of English cholera, or summer diarrhœa, the medical officer of health estimating the cases at fully 500, chiefly children under 18 months. The deaths have numbered 50 The outbreak is attributed to the long spell of hot weather, with the attendant contamination of milk and other food-supplies and interference with drainage. The medical officer of health has advised the boiling of all milk consumed by children, and regards flies as a fruitful cause of spread of infection.

August 29th.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENT.)

Serious Accident to a Bristol Surgeon.

Dr. H. G. Kyle, one of the surgeons to the Bristol General Hospital, met with a serious accident while travelling through Shropshire on a motor cycle. The exact reason for his fall is not known, but the resulting injuries to the head and right shoulder are very severe, and his condition gives cause for grave anxiety. Dr. Kyle has a wide circle of friends in Bristol, and they are receiving information daily from his relatives who are staying with him at the house to which he was taken after his fall.

A Plague of Crickets.

During the hot weather the Bristol health committee was confronted by an unusual problem. Robertson-road, Eastville, was for several weeks swarming with crickets. The centre of attraction appears to have been a heap of refuse deposited by the authorities at the neighbouring workhouse, but the houses in this and other streets were freely invaded by hosts of insects. Various insecticides were tried; carbolic acid and lime were ineffective, and petrol, which was more efficacious, was too costly for wholesale use. Fortunately, the end of the trouble came when the hot weather passed; but while it lasted the people of the district were put to very serious inconvenience.

The Bristol Guardians and Hospital Accommodation.

The Bristol board of guardians is at present much exercised as to the means of providing adequate hospital accommodation. A scheme for demolition of existing premises on a large scale with erection of a new building has been passed, but it is being opposed by a strong minority, who plead for a smaller and more economical change in view of the present uncertain state of Poor-law affairs. This difference of opinion has been productive of many debates, some of them more conspicuous for heat than light. There is no doubt that it is a very serious matter, for the scheme which has received the sanction of the majority is a costly one. It is an interesting fact that one part of the doomed premises at Fishponds was built in the eighteenth century as a prison, and was used for years for the incarceration of prisoners of war.

Medical Practitioners and Public Servants.

At the last meeting of the Bristol board of guardians a letter was read from the guardians of the Merthyr Tydvil Union enclosing a copy of a resolution adopted by them as follows:—

That this board, being of opinion that it is better to pay for the prevention of disease rather than for the cure of same, believes that the time has now arrived when the medical practitioners of this country should become public servants. That copies of this resolution be sent to the President of the Local Government Board, local Members of Parliament, and to all boards of guardians in the country.

The Bristol guardians, after a slight discussion, dropped the matter.

Rural and Urban School Children.

The school medical officer of Wilts (Dr. R. H. Bremridge), in his annual report for 1910, which has been recently issued, states that the rural children are superior to the urban children in every physical characteristic of which he had taken notes, the rural standard of cleanliness is better, and the advantage of the rural over the urban area in the matter of height and weight was demonstrated.

The Royal Albert Hospital, Devonport.

At a special meeting of the governors of the Royal Albert Hospital it was decided to realise stock value £1083 and to devote the proceeds to the general maintenance fund. It was stated that, under the most careful management, the expenditure had for many years exceeded the income by about £800 per annum, and the present adverse balance against the hospital was £2640.

The Water-supply of Ilsington (Devon).

A Local Government Board inquiry was recently held at Ilsington into an application of the Newton Abbot rural district council for sanction to borrow £4900 for the purpose of water-supply.

Spotted Fever in the West of England.

At the last meeting of the Holsworthy (Devon) rural district council the medical officer of health (Mr. W. G. Gray) reported eight additional cases of "spotted fever," with three deaths. He asked the council to provide shelters and isolation accommodation, but this was not granted, and the matter was adjourned for a fortnight. There is a feeling of great dissatisfaction at the attitude of the Holsworthy rural district council in not supporting their medical officer of health, whose action has been warmly commended by the Local Government Board inspector (Dr. R. J. Reece), and also by the medical officer of health of Devon (Mr. G. Adkins). The local press has made several strong comments upon the council, and the *Western Morning News* urges the interference of the Local Government Board. The Tavistock (Devon) rural district council, owing to two cases of spotted fever having occurred in its area, and acting upon the advice of its medical officer of health (Mr. C. C. Brodrick), decided to provide isolation accommodation for the district and to make the disease notifiable.

Sanitary Inspectors and the Local Government Board.

At the last meeting of the Redruth (Cornwall) rural district council it was reported that the Local Government Board had refused to sanction the appointment of a certain sanitary inspector for a portion of the district. The Local Government Board stated that its inspector (Dr. S. W. Wheaton) had informed the Board of the unsatisfactory state of the district, and it was not willing for such a state of things to continue. The Board therefore urged the council to appoint a qualified sanitary inspector for the whole district, and to give him an adequate salary.

Death of William Steer Riding, B.A. Lond., M.D. Edin., M.R.C.S Eng., L.S.A.

Dr. William Steer Riding died at his residence, "Stamlands," Buckerell, Devon, on August 19th, in his seventy-sixth year. Dr. Riding, who graduated as M.D. at Edinburgh University in 1857, had at one time an extensive practice in London, where he resided at Endsleigh-gardens, Euston-square. He retired from active work about 20 years ago and took up his residence at Buckerell, near Honiton. He was very popular in the district, and the poor have lost in him a good friend. He leaves a son and two daughters to mourn their loss.

August 29th.

WALES.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Consumption in Newport.

FOR several years past the Newport board of guardians has had special accommodation for consumptive patients. A large house, apart from the workhouse and in its own grounds, has been utilised for the special treatment of these cases, and by the erection of huts as many as 37 patients can be accommodated at one time. The corporation has erected a wooden pavilion in the grounds of the isolation hospital for the accommodation of ten patients, and in his annual report for 1910 the medical officer of health, Dr. J. Howard-Jones, states that during the year there were treated in this pavilion

102 patients. Unfortunately, as in previous years, the majority of the patients were in an advanced stage of the disease. Some had not sought advice until their chances of recovery had become imperilled, while others, though under medical treatment, had not been informed until a late period of the nature of their ailment. Notwithstanding this drawback, Dr. Howard-Jones considers that the results attained by the segregation of cases in an infectious stage fully justify the cost entailed. As a rule, each patient stays in the institution for one month; in exceptional cases for a longer period. On returning home they are encouraged to keep in touch with the medical officer of health. They are visited in their homes and are urged to carry out the lessons inculcated during their stay in the sanatorium.

The Nursing Arrangements in Dolgelly Workhouse.

At a recent meeting of the Dolgelly board of guardians Mr. Hugh Williams, Poor-law inspector of the Local Government Board, urged very strongly the appointment of a trained nurse for the workhouse infirmary. At present, he said, only about 20 per cent. of the workhouses of the country were unprovided with trained assistance. The rate of pauperism depended upon the way the Poor Laws were administered, and there was no doubt that if the amount of sickness could be reduced by proper nursing a considerable saving would be effected in the cost of relief. The medical officer, Mr. John Jones, endorsed the recommendation and stated that the patients then in the infirmary required careful and skilled attention. The proposal was opposed by several members of the board, apparently on financial grounds, though one guardian openly avowed that he had no faith in doctors or nurses, and stated, in all seriousness and as an unanswerable argument, that there were several cases in which patients had died after being nursed. In the end decision on the question was postponed for two months.

West Wales Joint Asylum.

The dispute which has been going on for many years past between the county authorities of Cardigan, Carmarthen, and Pembroke, with respect to certain charges connected with the asylum belonging to those bodies, has at last been brought to a satisfactory termination. Many improvements, including arrangements for proper classification, are now rendered possible, and suitable additions to the asylum buildings will lessen the existing overcrowded state of the institution, in which the number of inmates on March 31st last was 687. In his recently issued annual report the medical superintendent, Dr. John Richards, refers to the importance of keeping under surveillance patients discharged as recovered. He suggests that they should be medically supervised and, when necessary, monetarily assisted for several months after leaving the institution. One male patient died during 1910 at the age of 106. He had been an inmate of the asylum from the date of its opening in 1865.

The Rhondda Health Report.

The population of the Rhondda urban district at the last census was 152,798, an increase of 39,063 upon that recorded in 1901. There are now only 18 county boroughs and one urban district, that of Willesden, with populations exceeding that in the Rhondda valleys. In his annual report for 1910 the medical officer of health, Dr. J. D. Jenkins, refers at length to the infantile mortality, which has always been high in the district, averaging in the past ten years 178 per 1000 births. In 1909 it was 129 per 1000 and 136 in 1910. During these two years two health visitors have been employed in the district. It appears, however, that their work was restricted to one portion of the district in which the infantile mortality rate in 1910 was 142 per 1000, while in the remaining portion of about the same population the rate was only 130 per 1000. The death-rate from diarrhœa, which was 0·29 per 1000 in England and Wales in 1910, was 0·83 per 1000 in the Rhondda, and of those who died from this cause over 80 per cent. were under one year old. As the Rhondda is essentially a water-carriage locality, and as there is no storing of household refuse in the immediate vicinity of dwellings, it is necessary to seek for some cause of this prevalence of diarrhœa other than that which is to be found in the northern counties—namely, privies and dustbins. It appears, however, that although there is a daily removal of refuse from the dwellings in the Rhondda, it is carted to huge mounds at no great distance, and Dr. Jenkins states that these "tips" afford a suitable breeding-ground for flies, an excessive number being noticeable in the houses nearest to the accumulated refuse. He asserts that the abolition of the "tips" will be instrumental in reducing the death-rate in the locality concerned, and especially so amongst young children. There are no less than 200 loads of refuse to be dealt with daily, only about one-tenth of which is disposed of in the destructor erected in 1900. Power has been sought, however, to purchase land and to erect destructors in four different parts of the district, and also to use the existing tramways to convey the refuse to the destructors. The erection of these destructors is without doubt the most urgent matter claiming the attention of the council. The staff of six sanitary inspectors, which has not been augmented for 12 years, and which has only been increased by one since the time when the population of the district was half that of the present time, appears quite inadequate for the proper carrying out of the duties imposed by the Local Government Board. Dr. Jenkins states that among the subjects which have to be neglected owing to the insufficiency of his staff are the inspection of meat and food supplies, measures specially aimed at the prevention of pulmonary tuberculosis, inspection of the gathering grounds of the many different areas of water-supply, and the sanitary administration of workshops and workplaces.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Proposed New Nursing Home for Edinburgh.

THE executive committee of the proposed new nursing home for Edinburgh has acquired a block of three houses in Chalmers-street, Edinburgh, as the site of the new home. Of the £10,000 required a sum of £8640 8*s.* 11*d.* has now been subscribed. The home, it is expected, will be self-supporting.

Voluntary Health Visitors of the City of Edinburgh.

The work of the voluntary health visitors in connexion with the Public Health Department of the city of Edinburgh continues to maintain the satisfactory level of efficiency which was reached in the first years after the initiation of the scheme. The medical officer of health, in his report for 1910, announces a reduction in the rate of infantile mortality from 113 in 1909 to 103 in 1910, and states: "There can be little doubt that, in addition to the general improved sanitary condition of the city, much of this result has been obtained through the sustained efforts on the part of the large body of voluntary lady health visitors who for some years past have dealt with this whole question in a manner which can only be characterised as thorough in every detail." The Notification of Births Act gives to the public health department knowledge of the birth of a child within 36 hours, and in the cases where notices come from homes where no paid medical man has been in attendance visitation of the infants is undertaken. As soon as possible after receipt of the notification the official lady health visitor pays an initial visit, and then passes on slips with the information to the secretaries of the voluntary visitors. The secretaries receive the notices each week, distribute the cases to the captains of the various areas, and the captains in turn distribute them to the individual visitors. The visitors are required to visit fortnightly—and much oftener in case of illness—while after each fortnightly visit a report of the condition of the child has to be made out on a printed form and given in to the public health department. In the end of 1910 there were 267 ladies engaged in the work and 1249 infants were under visitation. The total number visited during the year was 2395. During the winter of 1909–1910 three sets of five lectures were delivered to the visitors, the subjects being "Infant Life," by Dr. Beatrice Russell; "Infection," by Dr. John Thomson; and "Some Methods of Charity," by Mrs. George Kerr, honorary secretary of the City of Edinburgh Charity Organisation Society. The visitors attending the lectures were charged 2*s.* 6*d.* for each set, and this charge more than covered the expenses of the lectures, including the lecturers' fees. Voluntary health visiting, as carried on in Edinburgh, is a demonstration of how satisfactory and efficient such

work may be if well organised. The object the visitors have set before them is to reduce the rate of infantile mortality in Edinburgh to the lowest possible figure.

Glasgow Western Infirmary Extensions.

An important addition to the buildings of the Western Infirmary, Glasgow, is to be formally opened by Sir James Barr, on Oct. 13th. The addition comprises a clinical laboratory erected at a cost of £5000, given some time ago by an anonymous donor. The laboratory will be not only of great service educationally, but will, it is confidently hoped, prove of much assistance in the curative work of the infirmary. Its equipment has formed the subject of the fullest possible inquiry, including visits to several of the best-known continental hospitals. A further extension scheme is on foot for the hospital, and one which is urgently required. This scheme aims at the construction of a reception ward with operating theatres overhead. This building will fill up the gap between the main building and the new wing, and from the point of view of administration alone the linking-up of these buildings will be of considerable convenience. Apart from this consideration, a commodious reception-room is urgently needed. The sum aimed at to cover the expense of the further extensions is £80,000, and while a considerable proportion has already been subscribed, fully £20,000 more are required to complete the cost of the scheme.

Leanchoil Hospital, Forres.

At a recent meeting of the managers of the Leanchoil Hospital, Forres, it was intimated that a legacy of £1000, free of legacy duty, had been left by the late Mr. George Cunningham of Forres, to found a bed to be called "The George Cunningham Bed."

New Infirmary, Perth.

On the afternoon of Saturday, August 26th, in the presence of a distinguished and representative company, the memorial stone of the new infirmary for the county and city of Perth, which is in course of erection at Tullylumb, Perth, was laid by Mrs. C. A. Murrey, Taymount, wife of the chairman of the institution. In the new infirmary there will be 120 beds, and of the sum required, which is estimated at £36,190, £33,022 have been subscribed, leaving £3168 to be raised. It is also proposed to erect and endow a children's ward, as the city and county's memorial to the late King Edward, the cost estimated at £2000.

August 29th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Old Age Pensions in Ireland.

THE recent annual report of the Local Government Board on the working of old age pensions makes sad reading. From the date of the Act coming into operation until July 1st, 1911, the total number of appeals received by the Local Government Board actually numbered 49,190. It is deplorable to find, as pointed out in this report, a tendency on the part of almost every small landholder in Ireland, on reaching the age of 70 years, to transfer his farm to some member of his family and then claim a pension as a matter of course. The fact is, in Ireland the Old Age Pensions Act has totally undermined the independence of a large number of people, and to-day there are thousands in receipt of pensions in Ireland who neither need nor deserve them. Again, in this report it is shown that many representations from boards of guardians have been made to the Local Government Board, complaining of their being unable to recover any part of the cost of the maintenance of an old age pensioner who temporarily seeks medical relief in a workhouse infirmary, and urging that Section 6 of the Act should be amended so as to enable them to draw the pension during the pensioner's stay in the institution. It is clear from the report of the Local Government Board that the Old Age Pensions Act has raised problems in Ireland which will cause great trouble in the near future.

Death-rate of Dublin.

In the annual report of Sir Charles Cameron, medical officer of health of Dublin, the death-rate of Dublin is shown to be 10 per 1000 higher than the average of the great English cities, and practically double that of London. Moreover, it is high not only among the poorer classes, but among the professional and well-to-do middle-classes. The cause lies, doubtless, in the housing of the poor. There are 211 cases in which nine or more people are living in one room, nearly 4000 with six or more, and nearly 10,000 with four or more. It is obviously impossible to obtain health or decency under such conditions. The various housing schemes of Lord Iveagh, the Dublin corporation, and others have afforded little relief, since they cater for the artisan rather than for the labourer and the very poor. The city architect recently made the very proper suggestion that to cope with the housing question thoroughly all hope of making any scheme self-supporting must be abandoned. The return to the community must be looked for in the health of its citizens and not in money. The corporation, however, spends money lavishly at present in all its departments, and taxation is at its limit, so that it will not be easy to gain consent for an expensive housing scheme. In the meantime, much might be done by a rigid system of inspection of the tenement houses, with enforcement of the by-laws, where any default is shown.

Dispensary Medical Officers and the Insurance Bill.

A meeting of "dispensary doctors"—i.e., Poor-law district medical officers—was held in Dublin during the recent Public Health Congress, to consider the special menace to their interests by the National Insurance Bill. The proposal of the Irish Parliamentary Party—viz., to omit medical benefits from the scheme as applied to Ireland—is regarded as particularly dangerous to Poor-law medical officers. If sickness benefits are to be given without medical benefits the Health Committees will require medical certificates and other safeguards against malingering, and are likely to demand, as the Bill gives them power to do, such extra services connected therewith from the dispensary doctors. Resolutions were therefore passed that the Poor-law medical officers of each county should meet to discuss their position and prospects under the Bill, at a meeting to be held in Dublin early in October.

On August 17th a conference was held in the Engineers' Hall, Belfast, to which trade union and friendly society officials were invited, to make recommendations as to amendments necessary to render the Insurance Bill applicable to Ireland. The President of the Trades' Council occupied the chair at this conference, which was entirely composed of members of the Labour Party, as the invited representatives of the Friendly Societies were unable to attend. The meeting disclosed the opinions of the working classes, and the views were made public of a deputation from the Belfast Trades and Labour Council which had interviewed in London the Chancellor of the Exchequer and the Labour and Irish parties. The chairman said he had reason to reconsider the good opinion he originally formed as to the Bill, and he was coming to the conclusion that "all that was left of the fine scheme introduced in such glowing terms by Mr. Lloyd George—at any rate, so far as it applied to trades unionists in Ireland—was not worth fighting for. Further, he did not see why they should be expected to 'kow tow' to the Friendly Societies." A member of the deputation to London said that Mr. Redmond had told them that 75 per cent. of the people were against the medical benefits part of the Bill. The agricultural portions of the country were opposed to the medical benefits, which would be of value to only five counties in Ireland. When the Irish Party were asked if they could have that part of the Bill made applicable to Ulster alone they were told that that the matter would receive sympathetic consideration. Another speaker said Mr. Lloyd George told them he would be guided by the votes of the Irish Members, and that party was going to exclude Ireland from medical relief benefits and to maintain the present dispensary system in Ireland, though giving Englishmen the right to choose their own doctors—a somewhat strange attitude for the Irish Party to take. Finally, a resolution was put forward that Ireland should not be excluded from medical relief or unemployment benefit under the scheme, and that out-workers should not be excluded from the operation of the National Insurance measure; to which an amendment was offered "that while this meeting approves of certain of the privileges of the National Insurance scheme, it demands the withdrawal of the

present Bill as being unsuited to the workers." After a long discussion the conference, at which there was a large attendance, was adjourned until the next meeting of the Trades Council. On August 12th at a meeting in Thurles of the dispensary doctors of county Tipperary, resolutions were passed to the effect that if medical benefits were deleted, while sickness benefits were retained in the Insurance Bill as applied to Ireland, the dispensary doctors' medical work would be enormously increased without provision for proportionate remuneration. So far as Ireland is concerned, in dealing with the Insurance Bill next autumn Parliament may adopt one of three courses: (1) Decide that it will not apply to Ireland; (2) delete medical benefits; or (3) arrange that in Ireland the Bill be so altered as to make one part apply to the industrial centres and the other to the agricultural districts. Unquestionably the worst and most unworkable scheme would be the second.

Registration of Milk Purveyors.

At the Belfast summons court on August 21st a farmer in county Down, who daily brings milk into Belfast, was proceeded against for not being registered as a purveyor of milk under the Dairies, Cowsheds, and Milkshops Order, 1908. The defence put forward was that registration in Belfast was not required as this had been done in county Down; but the corporation, which prosecuted, contended that the registration of the vendor was required in the district in which the milk was sold—in this case Belfast. The corporation is rightly seeking to establish power of inspection over all milk-carts from which milk is sold in the city. Only about one-half of the dairymen residing outside the city who vend their milk in Belfast are registered with the corporation. The case was therefore a test one, and it is satisfactory to find that the magistrates convicted and also refused to state a case for the higher courts, although the legal adviser of the milk vendor said he would serve notice for a case.

Death of John Henry Harbison, M.B., B.Ch., B.A.O. Q.U.I.

Widespread regret is felt among the younger members of the medical profession in Belfast at the tragically sudden death of Dr. John Henry Harbison, demonstrator of physiology, in the Queen's University, Belfast. While on a visit to a brother in Liverpool he was attacked on August 12th with tonsillitis, to which he succumbed on August 14th. He was buried in Cookstown, county Tyrone, on August 16th. A native of Cookstown, Dr. Harbison received his early education at St. Patrick's Academy, Dungannon, and Blackrock College, Dublin. A distinguished intermediate exhibitioner, he entered Queen's College, Belfast, where he was a scholar, and graduated in 1910 as M.B. at the Queen's University, Belfast. He subsequently was house surgeon in the Mater Misericordiæ Hospital, and when his term of office there expired he was appointed demonstrator of physiology at Queen's College, Belfast—a post he held at the time of his decease. A man of exceptional ability, a hard worker, and with a very amiable character, Dr. Harbison was most popular with all who came in contact with him.

Death of Robert Chambers, L.R.C.P. Irel., L.R.C.S. Eng.

The death of Mr. Robert Chambers occurred at his residence, Westwood, Ravenhill Park, Belfast, on August 28th. Mr. Chambers, who was born in county Tyrone, studied in Dublin and Edinburgh. He settled in practice in London, where he was superintendent of the Marylebone Medical Mission, physician to the Church Army Training Homes and Shaftesbury Institution, and physician to the London Medical Mission. Mr. Chambers came to Belfast on his retirement from the active duties of his profession a couple of years ago. He was always deeply interested in religious work, and took a prominent part each year in the well-known Keswick Convention. He was devoted to floriculture, being an enthusiastic rose-grower. General sympathy is felt for his widow.

August 29th.

DEVON CHESS CHAMPIONSHIP.—Mr. Robert Dunstan, M.R.C.S., L.S.A., of Torquay, has won the Winter-Wood Cup, which will be presented to him at the annual meeting of the Devon County Chess Association.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A Period of Congresses.

AUGUST is the month of congresses. France has had four during the past few weeks. The French Association for the Advancement of Science, one of the most important of scientific congresses, held its annual meeting at Dijon. Medical subjects constitute one of its sections, and one which seldom lacks interesting communications, especially from provincial savants. For instance, this year M. de Janicot, chief of the laboratory at the Lyons Faculty of Medicine, dealt with the teaching of puericulture, which, according to him, should be entrusted to female teachers. Dr. Ziffel, a professor of the Medical School at Dijon, insisted on the point that no child should be admitted into any school until after it had undergone a medical examination. In the section of anthropology Dr. Marcel Baudouin presented a general classification of the human osseous lesions of the neolithic age. Finally, in the section of medical electricity M. Weill, M. Vincent, and M. Barre of Paris presented a communication on Electrical Examination in Diseases of the Ear. The members of the Congress attended the exhibition of medical electricity open at Dijon during the Congress.

The French Congress of Stomatology was opened in Paris on July 31st at the Faculty of Medicine in the Grand Amphitheatre before a numerous attendance of French and foreign medical men. M. Landouzy, Dean of the Faculty of Medicine, delegate of the Minister of Public Instruction and Fine Arts, presided over the first session and delivered a presidential address that was highly appreciated. The principal communications presented were those of M. Tellier (Lyons), on Pyorrhœa Alveolaris; of M. Bezo (Paris), on Classifications in Orthodontia; of M. Cruet on the Unity of Accidents of Dentition; of M. Caillon (Lyons), on the General Principles of Bucco-dental Prophylaxis; of M. Hallopeau, on the Local Treatment of Syphilides of the Tongue; of M. Béal (Lille), on Tetaniform Accidents of Dental origin; and of M. Rousseau-Decelle, on the Influence of Bucco-dental Irritations on the Production and Evolution of Dermatoses. M. Chaminade (Bordeaux) discussed the conclusions to be drawn from a statistical examination of 1000 chloroform anæsthesias and 1500 anæsthesias with ethyl chloride. On August 3rd a closing banquet was held, at which a large number of medical men were present.

About the same period the Twenty-first Congress of Alienists and Neurologists of the French-speaking countries opened at the Hôtel de Ville, Amiens, under the presidency of Dr. Deny, physician to the Salpêtrière, with delegates from the Ministries of the Interior, of War, and of Marine, and some 15 representatives of medical societies. The mayor welcomed the members and Dr. Deny responded, while M. Granier, Inspector-General of the Administrative Services, and delegate of the Minister of the Interior, extended the good wishes of the Government to the Congress. The first session was almost entirely devoted to a debate on the report of Dr. Maillart, physician to the Salpêtrière, who discussed the different kinds of psychopathic pains. Dr. Paugniez (Amiens) communicated a series of observations on suggestion by beauty, an influence which, without abolishing the mentality of the subject, exercises an external authority, giving rise to an idea capable of awaking other ideas associated with it, and ending even by determining actions which, if left to itself, the will of the subject would be incapable of accomplishing. He cited in support of his theory the influence of Agnes Sorel over Charles VII. From the time of her appearance at Court Charles VII. rose to the demands of his high position, comported himself with the confidence of a man defended by a talisman, and every year marked a victory. When Agnes Sorel died in 1440 the King forthwith fell back into a life of idleness and debauchery. M. Courtellemont presented a long communication on tumours of the pituitary body, which was discussed by M. Laignet, M. Lavastine, M. Paul Sainton, M. Meige, and M. Dide. M. Dupré and M. Lagre read a paper on the relations existing between hysteria and

mythomania. M. Meige gave vent to some admirable remarks on the correction of functional troubles of speech. The value of the testimony of the insane in the courts was the subject of a very interesting communication by M. Lalaime, physician in chief of the Insane Asylum of Maréville, near Nancy, the paper evoking considerable discussion, in which many took part. This important session closed with a visit to the interesting museum of Picardy and ancient Amiens. It was decided that the next Congress should be held at Easter, 1912, at Tunis, under the presidency of Dr. Mabille (La Rochelle), and that of 1913 under the presidency of M. Arnaud.

Death of Professor Dieulafoy.

French science, and particularly medical science, has sustained a severe loss in the death of the eminent Professor Dieulafoy, Commander of the Legion of Honour, and a Member of the Academy of Medicine, who passed away somewhat suddenly on August 16th. He was born at Toulouse in 1839. He was a pupil of Trousseau, and had a distinguished career both as resident in the hospital and on various hospital staffs. After occupying the chair of Clinical Medicine at the Hôpital-Necker he proceeded in 1896 to the Hôtel-Dieu, where he became successor to Trousseau. In 1909 he was associated with the tuberculosis service at the Hôpital-Laennec. He published a very valuable number of works, among which must especially be mentioned his "Manuel de Pathologie Interne," which has been translated into nearly every language. As a practitioner he was highly talented, and it was he who popularised, in 1869, the aspiration treatment of pleurisy. To an extraordinary intellectual capacity he joined an open mind on all points. Not only a savant, he was also a man of letters and a devotee of the arts, and a collector of modern paintings. His fine character and kindly qualities endeared him not only to his professional colleagues, but to all with whom he came into association.

August 28th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Cholera Epidemic.

THE Marquess Incontri, a young and aspiring member of the Chamber of Deputies, has given notice of the following interpellation to be addressed, on the reopening of Parliament, to the Minister of the Interior:—

> To be informed as to the reasons for which silence has been maintained on the true state of public health throughout the kingdom—silence which gives warrant to the grave apprehension entertained in foreign countries, and which, concurrently with official communications not in harmony with the truth, prevents the people, in their ignorance, from putting in practice the elementary rules, hygienic and prophylactic, indicated by circumstances.

This announcement gives voice to the dissatisfaction shared by Italians at the reticence of the Government during the prevalence of a disease which has already assumed an epidemic character, thus leaving to municipal or communal initiative what ought to be official procedure emanating from headquarters. The interpellation cannot be made till November next when the Chamber meets, but it may, in the meantime, have the effect of bringing home to the Government the duty of frankness, or, to put it plainly, of that moral courage, which was so culpably wanting last year, when the public were kept in the dark as to the presence of cholera on the Adriatic seaboard and were only apprised of the danger when the disease had already effected a landing at the ports of the Two Sicilies. Much has been made, as a motive for this reticence, of the dread of scaring away the foreign visitor or "paying guest," and the association for promoting the influx of that source of revenue has been blamed for inspiring the Government with its "policy of silence." But such, I am credibly informed, is not the fact, any more than it is a fact that the interests of the Exhibition still open in the capital, and not too largely frequented, are similarly responsible.

The late summer and the early autumn are not the season when foreign visitors are expected, and the silence in question, this year as last year, may in truth be set down to the traditional supineness of Latin officialdom when confronted with such visitations. To such lengths has that ill-inspired tradition gone that it was recently announced by the telegraphic agency under Government control that at Leghorn, for example, not a single case of cholera had occurred when, according to the Marquess Incontri, who is in close touch with that seaport, "the disease had for weeks been numbering victims daily," when (still according to that authority) "in all the centres of Tuscany, great and small, the presence of cholera was a theme of general conversation," when, in fact, villas and palatial residences were being abandoned as early as the first days of July! Another significant fact is vouched for by the Tuscan Deputy. "A recent official circular requires every householder to report any cholera case within 24 hours of its occurrence, at the same time charging the medical man not to pronounce or to write the terrible word! The inevitable consequence of all this is the imbroglio in which Italy has been involved with other Powers, whose suspicions of her sanitary state have deepened into something like conviction of the sinister reality, causing trouble for her at their ports, with suspension of all business, commercial and other, notably in the Argentine and the United States. Her rivals, moreover, in catering for the "paying guest" have been only too eager to utilise this "atmosphere of doubt and dread"—hotel-keeping Switzerland, for example, flaunting announcements in its bureaux that "subscriptions are gratefully acknowledged here for the cholera-stricken Italian centres," while at the same time assuring the arrivals that the fruit and vegetables supplied at the table do not come from Italy.

In the towns where cholera has effected a foothold, the authorities, in the absence of direct Government intervention, are left to their own, not always well-inspired, initiative, having to act in isolation, not in harmony with the neighbouring centres, some of them having to depend on the medico-military service only, which has not always the means or the *matériel* for efficacious action. A notable exception to this haphazard procedure is afforded by Leghorn, where the disease has been so prevalent and the panic so great that 30,000 of the population—all, in fact, who had the means—abandoned the city, but where the municipality and those of the citizens who remained exerted themselves nobly, substituting at their own expense pure water from without for the notoriously defective supply hitherto available, till the Government has at length intervened with the subsidy of 15,000 francs in aid of their operations. This subsidy—none too liberal—has been supplemented by the Minister of Marine, who, in addition to the "acqua potabile" imported from Massa and the Maremma, has embarked at Naples, from the pure source of the Serino, 250 tons of water. Such and similar measures have already reduced the mortality at Leghorn considerably, with the result that the fugitives are beginning to return. Genoa, too, and the neighbouring towns are showing the Government an example of what non-official energy can do, although the local conditions in some of these are of the worst imaginable. At Sori, for example, the water-supply has been so bad that during the drought it has to be drawn from a well, the water of which poisoned no fewer than 20 of those who drank it, and as many as 15 died!

The truth is that it is only on occasions of epidemics like this that the majority of Italian communities awake to the insanitary conditions under which they are content to live, while the lessons then inculcated, though taken to heart at the time, are soon forgotten on the disappearance of the visitant. Poverty, too, comes in to embarrass the authorities and often to frustrate their action. At Florence, happily immune from the epidemic, a quantity of fruit was impounded by sanitary order and carted away to a retired spot in the Cascine (the "Bois de Boulogne" of the City of Flowers). But the moment the coast was clear a number of fruit vendors picked up the more "plausible" looking of the peaches, apricots, or apples, washed them in the Arno close by, and disposed of them again! The incident shows with what adverse forces the public hygiene of Italy has to struggle, and explains how ineffective is the fight she makes in such disastrous visitations as the present.

August 27th.

THE BARNSTAPLE (DEVON) BOARD OF GUARDIANS AND THE NORTH DEVON INFIRMARY.—At the last meeting of the Barnstaple board of guardians it was decided to give a donation of £25 to the funds of the North Devon Infirmary.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Precautions against Cholera.

ON account of the threatening epidemic of cholera the Minister of Internal Affairs has ordered that the county magistrates shall provide in every town and village adequate accommodation for any cases that may occur. Persons coming from localities known to be infected are to be medically examined, and if they present suspicious symptoms they will be isolated for at least a fortnight. Villages which cannot afford to erect the necessary buildings from local funds will be helped by the State. In the event of an outbreak the maintenance of the patients and the wages and salaries of the nursing and administrative staff will also be provided at the expense of the State. Circulars have been sent to medical men inquiring whether they will in case of need undertake the treatment of cholera patients for a fee of 20 kronen daily with provision for their families in case of their death from the disease. Last week Dr. Gyula Bölcs, Ministerial Secretary, reported to the Minister of Public Health that all precautions against a possible invasion of cholera have been duly taken in this country, and that the sanitary authorities were in perfect readiness to deal with any cases that may occur.

Protection against Mosquito Bites.

The medical editor of the *Pesti Hirlap* has contributed to that journal an interesting article on the hygiene of holiday-making, in the course of which he deals with the prevention of mosquito bites. He recommends in the first place strong-smelling preparations for the hands and face, especially oil of lavender, oil of lemon, carbolated vaselin, vinegar, and turpentine. There is also tinctura pyrethri rosei, which has a very agreeable odour, does not stain the hands, and retains its active properties for four or five hours. Another very reliable preparation is "zacherlin," which is manufactured in Vienna. It is used as follows: 2 ounces of the powder are stirred up with a pint of alcohol, and the mixture is allowed to stand for one or two hours, after which it is filtered through blotting-paper, and the solution is then ready. This tincture, according to the observations of many medical men in Abbazia, keeps off the mosquitoes for a whole night.

The Average Lifetime of Hungarian Women.

The detailed statistical results of the last census were published at the end of last month, and the figures have been discussed by various medical men from different points of view. A noted Hungarian gynæcologist has examined the data available for comparing the duration of life of men and women respectively, and finds that women live longer than men. The average lifetime of Hungarian women, according to the census taken in 1880, was 42·5 years, but according to the last census it is now 51 years. In some parts of Hungary the improvement is still greater. For instance, in the Szckely district in Transylvania the average lifetime of a woman is 59·2 years. According to this gynæcologist the longer lifetime of women is due to their working less than men. The data of the present census show that there are now far fewer hysterical and nervous women than in former years. Insanity has also decreased slightly. These favourable results are chiefly due to the general prosperity of the country. Wages in Hungary have almost doubled during the last 10 or 20 years owing to the flourishing condition of agriculture, trade, and manufactures.

August 14th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Small-pox and Vaccination in the Province of Quebec.

SMALL-POX during the past few months has been very prevalent in most parts of the Province of Quebec. According to Dr. J. A. Beaudry, chief inspector of the Provincial Board of Health, there are at the present time many thousands of cases of small-pox in various districts in Quebec. For a period of 12 years, the same authority states, small-pox has been present to a greater or less extent in the province. The disease during this time has not exhibited itself in the form of a continuous epidemic, but has existed since 1899, each year in an almost uninterrupted fashion from November up to the month of May. One reason why the disease has not been brought under control is that it has been of a mild, and perhaps of a somewhat abnormal, type. Consequently the condition has not been diagnosed until a large number of persons have been infected, and not infrequently medical men themselves have diagnosed as chicken-pox cases which have really been true small-pox. But of all the reasons which may account for the continued existence and spread of small-pox in Quebec the neglect of vaccination is the chief. The occurrence of several cases of small-pox in Montreal and neighbourhood a few weeks ago brought matters to a crisis, and the Board of Health of the Province of Quebec took action under the powers conferred by Article 3875 of the Quebec Public Health Act. It issued an order that, in view of the increasing prevalence of small-pox throughout North America, as well as in the Province of Quebec, each municipal council of the province shall avail itself within five days of the receipt of this notice of the powers conferred on municipalities by the aforesaid article of the Public Health Act and of those given by Article 608 of the Municipal Code to adopt and enforce the necessary by-laws. These by-laws are sufficiently drastic to ensure general vaccination throughout the Province of Quebec if properly enforced. Although there seemed to be a considerable amount of opposition to obligatory vaccination in Montreal Dr. Beaudry is of the opinion that the antivaccinationists are not strong in the city. As is often the case elsewhere, they make up in noise for what they lack in numbers. Vaccination has not been prosecuted in a sufficiently strenuous manner, because small-pox hitherto has not been of a type virulent enough to constitute an imminent public danger. Indeed, familiarity with the disease has aroused the proverbial contempt. The results of enforced general vaccination in the province of Quebec will be instructive.

Filtration Plant for Montreal.

It is a year since preliminary steps were taken to provide Montreal with a filtration plant in order to ensure a pure water-supply. At first investigations were made as to the possibility of procuring water from the Laurentian lakes. It was finally decided to use raw river water as it was found that both lake and river water would require filtering and that it would be cheaper to filter the river than lake water, mainly because the city has already a plant in working order for the distribution of river water, while in order to obtain a supply from the lakes it would have to go to heavy expense and would nevertheless be compelled to employ filtration. The cost of the construction of a filtration system is estimated at £320,000. The land required for the purpose has been bought at Verdun, and tenders for construction work have been offered by four firms.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

City Owned Milk Stations of New York.

THE sum of £8000 has been appropriated this year by the city of New York for the maintenance of municipal milk stations, and the various milk-station organisations have formed an Association of Infants' Milk Stations. This association will avoid the duplication of effort and consequent waste of energy of former days, and afford a central office or clearing-house where close relations between the societies will be fostered, and whence information of value to each station and to the public will be disseminated. The Department of Health, which suggested this association, has admitted to it seven private organisations; in all 89 milk stations are represented. Up to now some 7000 infants have been regularly supplied with irreproachable milk. A physician is in attendance at each station, except where milk is sold by the glass at ½*d.*—less than cost—and gives free advice to mothers and prospective mothers. He is assisted by a nurse or matron, and visits are made to the homes of babies too sick to be brought to the station.

New York's Seaside Hospital for Babies.

Coney Island is said to be famed throughout Europe as a stupendously noisy and vulgar resort for New York's workers, and the idea of a home for sick babies amid such

surroundings is at first sight incongruous. The seaside hospital, however, is an immense success. It was formally opened on July 13th on land which, bought 30 years ago, is now worth £50,000. It stands ready for medical and surgical work, has diet-rooms, milk-rooms, irrigating-rooms, and all imaginable facilities required for treating the diseases of children, and a special fire-proof, isolated, fumigating plant for dealing with contagious disease. The building is constructed in such a manner that one section may be completely separated from the others, being independently heated and lighted, so that it may be run by itself if patients are not sufficiently numerous to fill a greater space. The hospital offers ideal conditions for the segregation and treatment of tuberculous cases, although not especially devised for that purpose. Accommodation is offered for 100 babies with their mothers. The hospital depends upon private charity, which, however, supports it bravely.

Industrial Welfare.

The American Iron and Steel Institute, one of the famous partners in the Steel "Trust," has begun an apparently serious attempt to revolutionise the condition of its labourers. Up to this time it has been the custom to work the men 14, and sometimes 24, hours a day, and to work for seven days in the week, relying upon the constant stream of immigration to keep the ranks filled. Now a beginning is made by ceasing work on Sunday and limiting the hours of daily toil to eight. A physician has been engaged to distribute literature among the 400,000 employees regarding the danger from the house-fly, the advantages of personal and domestic cleanliness, and other hygienic matters. It is believed that this movement will extend indefinitely, and will result in hospitals for those wounded in the course of their work, in the scientific regulation of drainage and so forth among the homes of the men, in the establishment of playgrounds and gymnasiums, and generally in the foundation of a state of unobtrusive paternalism on the part of the newly established "welfare committees."

Accident to Dr. G. G. Rambaud.

On August 2nd a high-powered car driven by Dr. Rambaud, director of the New York Pasteur Institute, and containing nine passengers, turned turtle, throwing out the occupants and injuring them all except a child of two years. Among the passengers was Mrs. Rambaud, formerly Mme. Gerville-Réache, the singer. Dr. Rambaud is at present in a Poughkeepsie hospital suffering from the effects of a perforated intestine, for which a laparotomy had to be done.

Cholera Scare Dissipated.

On August 4th the steamer *Madonna* reached New York from Providence, R.I., after remaining two days in quarantine under careful inspection with negative results. The *Madonna* came from Marseilles, Lisbon, and the Azores, and carried 63 steerage passengers. With this reassuring result the cholera scare may be said to be over, although there is some apprehension owing to the supposed presence of cholera-carriers in various parts of the country. Several supposed cases at the public hospitals turned out to be fright or hysteria, the relaxing effect of which upon the sphincters has been noted in previous scares.

Non-smokers' League.

The Non-smokers' Protective League of America, the latest organisation for the restraint of personal freedom, has been incorporated at Albany, N.Y. Its object is to prohibit the use of tobacco in all public places. One of the incorporators is Dr. Harvey W. Wiley, the Federal food and drug expert, who bids fair to forfeit much of his recently-earned popularity by this step. Many university presidents and professors appear in the list of incorporators.

A Diet Kitchen Association.

Special instruction for the "little mothers" who are in charge of young children is a feature of the summer work of the New York Kitchen Association and its nine branches. The physicians and nurses in charge give instruction in the preparation of milk, and similar matters, every morning to large audiences of the young guardians. On the recreation piers which jut out into the East and North (Hudson) rivers, other audiences of tenement house mothers with their children in their arms and clinging to their skirts listen to lectures on the construction of home-made fireless cookers, the preparation of ices without a freezer, and other hitherto undreamed-of mysteries. By these lectures it is hoped to attack the liquor problem at its root.

August 14th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Fouling of Water-supplies by Natives.

THE national habit of fouling and misusing the supplies of water in India is a matter of astonishment to all sanitarians who visit the country or are permanently engaged in sanitary work; not only do the people persist in their habits in spite of all warnings, but they claim for them a sacerdotal authority which, whether true or false, is none the less disastrous to public health. The sources furnishing drinking water are the rivers, lakes (natural and artificial), streams, tanks, and wells, and all these sources are fouled systematically; that most sacred river, the Ganges, is a vast sewer receiving the sewage of all the sewered towns on its banks, whether by underground or surface conduits, and also dead bodies more or less burnt according to the means of the survivors. The bodies of children are not burnt, and those of persons who have died from epidemic or contagious diseases are hurried by night to the river in order to avoid the attentions of the health inspector. The funeral dirge of the dead as the body is carried to the river may be heard in the small hours by people who sleep in hot weather on the flat roofs of houses. The resident engineer of Cawnpore city had occasion to visit Bhugwat Ghat, the most popular bathing place, on a public holiday. About 200 people of all ages and of both sexes were in the river, and a few yards above the ghat, and in the current flowing to the bathers, was a cholera corpse stranded on a small sandbank. The body had not been burnt, except on the lips with a hot ember, and it was in process of dissection by adjutant (scavenger) birds, which always begin their work by attacking the intestines, the contents of which were carried among the bathers. The latter all washed their mouths and drank of the water, and many carried home pots filled with it for domestic consumption. Others would walk home in their wet clothes even on cold mornings. All this is done in obedience to religious injunction. Hindus have a curious and widespread belief that flowing water purifies itself. The engineer above mentioned found a dhobi washing clothes in the Ganges on a convenient sandbank a few yards below the outfall of a Cawnpore sewer. The reason the man gave for choosing this spot was that the bank was convenient for drying, and that running water purifies itself. The engineer had occasion to inquire how far the sewage of the city could be traced down stream, using samples from above the sewers for comparison. Traces of sewage were found 18 miles below Cawnpore, although at the time only a small proportion of the sewage reached the river. Streams are fouled by every village they pass. The banks close to the stream are used as a public latrine, so that the people may make the special ablution that they say their religion prescribes. Contagion of various kinds may thus pass from village to village. A serious epidemic is generally followed by a pilgrimage to some shrine situated near some tank, river, or spring, and here the national habits come into play and are the cause of much anxiety and hard work among the public health and public work officials, who, to succeed, must combine much diplomacy with their science. There is nothing the Hindu is more jealous of than what he calls his religious customs.

Danger of Open Wells and Tanks.

Public wells are fouled continually from the time they are opened for use until the sickness of the users calls for cleansing. Popular tradition is again against the Hindu, for he believes that all drinking-water should "see the sun" which improves its quality, so his well is kept open; birds build in its crevices and trees grow by its edge, whose leaves drop into the water and decay. Fish and turtles are often put into the well with a view to improve the water, and as each user has his own rope and vessel, which, when not in use, are stored on the ground, the chances of contamination are numerous. It never occurs to the people that as the best water comes from the dark strata at the bottom of a new well, sunlight should not be admitted, and yet at the present time the corporation of Bombay meets with strong opposition from certain of the wealthy but half-educated citizens against the closing of wells, based upon religious grounds that ignore all reason and argument. In Bombay wells have been kept open with the certain risk of fouling, and with disastrous

results. The breeding of mosquitoes and the increase of malarial fever is greatest in the most densely populated wards of the city, where many of the old wells sunk in dwelling houses before the construction of the waterworks in 1859 are still in use. These wells are in a shaft common to every storey of the old houses, so that each flat can draw its own water. Such a well must, of course be kept open, and it furnishes a perfect breeding place for mosquitoes. Bombay has waterworks supplying at the rate of 32 gallons per head per day to the town, but, owing to lax control, the people have been bred in habits of wastefulness, so that the supply is never equal to the demand. Three-fourths of the population, belonging to the coolie class, never use more than 7½ gallons per day, but they will waste ten times that quantity if allowed. Waste has brought about an intermittent supply and the use of roof tanks for the storage of water. These tanks are closed and furnished with ball-cocks and lids. The admirable report on the causes of malaria in Bombay, recently prepared for the Government by Dr. C A. Bentley, has directed the attention of some of the citizens to their own premises. Many of them found that the lids of their roof tanks had been opened by the servants that the water might "see the sun," and the contents were found to be swarming with mosquito larvæ. This explained why the upper storeys, whose rents were highest, were infested with mosquitoes, while the lower rooms were comparatively free. Many villages and small communities depend for their water-supply on tanks, many of which, although their level may vary, are never dry at any season, and as each season's growth of water plants is followed by a deposit at the bottom of dead vegetation which is never cleaned out, impurities accumulate year by year. In addition there are the dejecta of fish and birds to be added, so that in spite of constant exposure to the sun the tank water is never pure. In the reservoirs of waterworks impurities chiefly of a vegetable kind accumulate. The new Vehar reservoir of Bombay was full in 1859, and was opened in 1860. In May, 1865, owing to deficient rainfall, the working level fell to 44 feet on the water tower gauge. The supply was at that time discoloured, thickened with vegetable matter, and offensive to taste and smell. The deaths registered in that month were 100 per cent. above the average. Forty-four feet of water had already been rendered impure by a very minute weed, one of the confervoid algæ, which in clear water seems to thrive at various depths, and on decaying gives off sulphuretted hydrogen. All permanent open bodies of water in India are invaded by plants, fish, birds, and crocodiles, and in many places the destruction of animal life in municipal reservoirs is strongly objected to on religious grounds by members of the municipal council. The choice of sources of supply for municipal waterworks has been rendered very difficult, for unless the catchment area is in a very sparsely populated district it is open to contamination. This often involves a long and expensive lead for the water.

Methods for Purifying Water.

India is a country in which the purification of supplies of potable water should be effected by chemical means rather than by the open sand filter; but here again popular apprehensions are on the lookout for "defilement," and modern systems, although in successful use in several places—notably at Betmangala, the source of supply of the Kolar gold-fields, where sulphate of alumina has practically abolished cholera—are objected to. The treatment of impure water at waterworks has been a good deal facilitated in America by an adaptation of the Venturi meter, by means of which the corrective, in liquid form, is introduced into the raw water main without the aid of a pump, and at a rate governed by the rate of flow, so that the proportion of corrective in relation to volume of water remains constant. This system is said to arrest deposits on the inner surface of the main, and the precipitate may be separated either in a settling tank or in one of the well-known pressure filters forming part of the main. When a natural head is available this arrangement offers a very cheap combination for a supply of drinking water. The popular idea regarding filtering sand was curiously illustrated in the municipal council of Cawnpore. A deputation of councillors waited on the construction engineer of the waterworks and informed him that, if possible, they would like the filtering sand to be taken from the Ganges as it contained particles that looked like silver, which made the water "more digestive." "Here," replied the engineer, "is a sample of sand straight from the river, and there is a second sample after 27 per cent. of mud has been washed out of it. You may now see the silvery particles with a lens; they are simply mica, which has no chemical affinity for water, but as the sand when cleansed is of a quality suited for filters it will be used to prepare the river water for your use." This explanation did not affect the popular belief, though the deputation returned to the municipal council with a satisfactory report. Among the schemes of primary education that at present are so much discussed in the Indian press there is no subject more deserving of attention than that of drinking-water and the care that should be taken to preserve it from fouling. If properly presented in primary schools it would certainly interest the pupils and would convey to them truths that would be of immediate and lifelong use.

Nastin B in Leprosy.

A report on Experiments with Nastin B on Leprosy, by Major S. Anderson, I.M.S., and Major L. Rogers, I.M.S., with notes by Colonel G. F. A. Harris, I.M.S., has just been issued in Calcutta. The report deals with the trial of the remedy at the Gobra Leper Asylum and the asylum at Purulia. The following are Major Anderson's conclusions: 1. All the cases treated improved in general health and gained in weight. 2. There was usually a marked local reaction in the nodules, or lepromata, and the general reaction was marked in many cases. In the nodular and mixed variety the commencement of improvement in a particular area was signalled by tingling or creeping sensations in the part. Treatment with intervals of rest is necessary; each case must be treated on its merits; and those patients who were most tolerant of nastin, and in whom no reaction occurred, undoubtedly showed the most improvement. 3 The improvement in the anæsthesia patches was generally marked; "all the cases showed an improvement in this respect." 4 Major Anderson's temperature charts show the action of the nastin. It is important to note that the injection of nastin was well borne so long as the air temperature did not exceed 100° F. He therefore recommends its use preferably in cold weather. He concludes by stating that "the nastin B treatment constitutes a real advance, and whilst it undoubtedly aborts the leprous processes in the same way as mercurials do in syphilis, and just as in syphilis one cannot say that the cure is permanent, so the same applies to nastin in leprosy." He considers nastin useful for prophylaxis and can immunise a patient so that he shall be no longer a danger to the community.

Malaria in Bombay.

Dr. C. A. Bentley, after investigating for two years the incidence of malaria in Bombay, has issued a valuable report. It shows an appalling prevalence of the disease, which is estimated at an annual pecuniary loss of 13 lakhs. He makes it clear that the island naturally is not very malarious, but that it is the highly developed portion of the island which is chiefly affected. Figures show that 75 per cent. of the breeding places of the anopheles are the wells and cisterns in and about houses. The Government of Bombay in a resolution says: (1) Measures should be directed against all mosquitoes, but the suppression or reduction of the species of anopheles that carry the disease must first be aimed at; (2) the measures must be so contrived and directed as to bring about not merely a mitigation of the disease, but the eradication of autochthonous malaria from the city; (3) the more rapidly the measures are carried into effect the greater will be the certainty of their complete success; (4) the main sources of infection are at present localised, but failing effective measures they may spread throughout the island. The responsibility for carrying into operation these measures devolves upon the municipal corporation of Bombay, and the Governor in Council trusts that the corporation will address itself to the task with energy and carry through the operations to success without delay. Dr. Bentley shows that, for an annual expenditure that may vary between two and five lakhs, Bombay could be completely freed from mosquitoes. The cost of measures directed against the malaria-carrier alone would not be much more than one lakh annually for the less infected wards, and the three worst infected wards could be adequately dealt with for half a lakh a year. The use of quinine as a prophylactic must not be neglected. It is to be trusted that the corporation will give early effect to this report.

August 8th.

Obituary.

GEORGE FIELDING BLANDFORD, M.A., M.D. OXON., F.R.C.P. LOND.,

LATE LECTURER ON PSYCHOLOGICAL MEDICINE AT ST. GEORGE'S HOSPITAL.

Dr. George Fielding Blandford, who died at his home in Tunbridge Wells on August 17th, was born on March 7th, 1829, at Hindon, Wiltshire, where his father, George Blandford, was a medical practitioner. He received his early education at Tonbridge School and went to Rugby, during the headmastership of Dr. Arnold, in 1841. Among those who entered Rugby in the same term were the late Professor F. J. A. Hort of Cambridge and Senator W. H. Waddington, Prime Minister of France under M. Grévy. In 1848 he matriculated at Wadham College, Oxford, where he took his B.A. degree in 1852, and at once entered on the study of medicine at St. George's Hospital. After proceeding to the M.A. degree in 1854 he qualified as L.S.A. in 1857, took the M.B. of Oxford in the same year, and became M.R.C.S. in 1858. In 1860 he was admitted a Member of the Royal College of Physicians of London. In 1867 he proceeded to the M.D. degree at Oxford, and in 1869 was elected a Fellow of the Royal College of Physicians.

Early in his professional career Dr. Blandford went for a short time to St. Luke's Hospital, Old-street, where he became acquainted with the late Dr. A. J. Sutherland, physician to the hospital and owner of the private asylum for male patients then known as Blacklands House, Chelsea, but later removed to Tooting under the name of Newlands House. Dr. Blandford went as resident medical officer to Blacklands House, an appointment at first intended to be merely temporary; but it was probably this appointment that determined his ultimate life work. In 1863 he entered on private practice, first in Clarges-street, but subsequently removing to Grosvenor-street, and then to Wimpole-street. He continued his connexion with Blacklands House (and its successor Newlands House) as visiting physician, and became physician also to Otto House, Kensington, a similar institution, under the same proprietorship, for ladies. These appointments he held until his retirement in 1909, so that his connexion with these institutions remained unbroken for about half a century. From 1874 to about 1895 Dr. Blandford was the principal proprietor of, and visiting physician to, Munster House Asylum at Fulham. This was ultimately closed and converted into a building estate, in consequence of the change in its surroundings by the extension of London making it no longer suitable for an asylum.

It will thus be seen how closely and importantly identified through his long career as a consultant physician Dr. Blandford was associated with psychological medicine, but he never allowed devotion to specialism to narrow his interests. While he was for many years lecturer on psychological medicine to St. George's Hospital Medical School, he served on the council of the Royal College of Physicians in 1887–8–9. In 1887 he attended the International Medical Congress at Washington, U.S.A., where he delivered the Address on Medicine on "The Treatment of Insane Patients." This address had been prepared for delivery to the Section on Mental Diseases, and he was altogether taken by surprise on finding that an address intended for an assembly of specialists was to be delivered before the Congress as a whole, but no one was more qualified than he to show how the developments and ramifications of a special subject must affect medicine generally. Dr. Blandford was a Fellow of the Royal Society of Medicine and had been vice-president of the Royal Medico-Chirurgical Society. He was also a past president of the Medico-Psychological Association of Great Britain and Ireland, and was president in 1894 of the Psychological Section of the British Medical Association, when he delivered an address on the "Prevention of Insanity." This address will be found in our columns and was recognised as an important pronouncement upon the development of neurotic affections attributable to the greater demands made by the requirements of modern life on the nervous system. The lecturer demonstrated that the exigencies of a complex civilisation, growing daily more complex, might result in the deterioration or exaggeration of certain faculties with a disturbance or complete overthrow of their proper balance, and urged that every effort should be made by attention to the important factor of heredity to prevent neuroses from becoming accentuated and intensified. Dr. Blandford stated that he had long been of opinion that insanity could be prevented chiefly by limiting the propagation of affected persons, and broadly gave it as his opinion that no man or woman should marry who has had an attack of insanity. From his personal observation he was inclined to adopt the view that the taint was transmitted through the female rather than through the male. He concluded his eloquent address by insisting upon the care that should be taken in the physical and mental nurture of children. At the time of his death he was president of the Society for the Relief of Widows and Orphans of Medical Men. In 1895 Dr. Blandford delivered the Lumleian lectures on "The Diagnosis, Prognosis, and Prophylaxis of Insanity" before the Royal College of Physicians of London. These lectures we published in full in THE LANCET. While the lecturer's discussion of insanity invaded the highest provinces of physiology, his remarks upon the tyranny of the examination system, which were received by his learned audience with uncompromising approbation, formed a most important part of the course. His words were not a sweeping indictment of modern educational methods in general, for he was mainly alluding to cases where there existed some predisposition to nervous breakdown. But he warned the College that while even the normal students are frequently overtried by the tests which the examination system may lay upon their intelligence, their temper, and their self restraint, to those who are mentally unstable such tests are positively dangerous. The gist of his advice was that where deficiency or instability was noted by parents or by medical advisers the optimistic view that the child may grow out of "it" must not be too readily followed. The words in which he delivered his message are as weighty to-day as they were then.

Of his contributions to medical literature, his text-book on "Insanity and its Treatment" passed through four English editions, the first in 1871, the last in 1892. An American edition also was published in Philadelphia in 1871, and in Germany a German translation by Dr. H. Kornfeldt. The value of this text-book was recognised on its first appearance, the practical parts of the volume being in particular written in a manner which made them very useful to busy practitioners. Dr. Blandford supplied a series of clear sketches of the actual varieties of insanity met with in practice which were at once more accurate and more comprehensive than any which had previously appeared in English manuals; while with regard to treatment, especially in relation to the all-important matter of feeding, he afforded useful guidance. His directions for the medical man in regard to legal complications which must arise in lunacy practice were admirable, as were his directions of the process of examining suspected lunatics.

He was also the author of the article, "Insanity," in Quain's Dictionary of Medicine; of those on the "Prevention of Insanity" and the "Prognosis of Insanity" in Tuke's Dictionary of Psychological Medicine; and of that on "Insanity" in the "Twentieth Century Practice of Medicine." He contributed also various lectures and papers on kindred subjects to our columns, the *Medical Times and Gazette*, *St. George's Hospital Reports*, the *Journal of Mental Science*, and the *Fortnightly Review*. In all his writings the same blend of academic learning and practical good sense, to which we have alluded above, was apparent. He was at one time also a contributor to the *Cornhill Magazine*, but many years ago he ceased contributing to general literature, which was considered by many a pity, as his classical education gave a cultivated turn to his tastes, and he had considerable literary gifts. His chief relaxation was sketching, which he took up somewhat late in life. In books, pictures, prints, and other objects of art he found continual pleasure, and he had the collectors' spirit which, though never indulged by him to an inordinate extent, found an outlet at different periods in accumulating old books and bindings, "Cruikshankiana," prints, etchings, and in particular a considerable collection of books and views relating to old London. He parted with these, however, in the autumn of 1909, when he retired from practice and went to Tunbridge Wells to spend the remainder

of his days. Dr. Blandford had been a member of the Athenæum for very many years.

When young, Dr. Blandford was active and athletic, accustomed to riding from his earliest years, a good cricketer, playing in both his school and college elevens, a footballer, and an oarsman. He took also an early part in the Volunteer movement, belonging for several years to the 2nd (South) Middlesex Regiment. But with the increase of professional work active occupations were given up, and for many years before his death he had led a quiet and sedentary life, which was, in fact, more and more forced upon him by rheumatism. Except for this condition, which had troubled him for years, though without incapacitating him, Dr. Blandford enjoyed remarkably good health from childhood up to the time of his last illness, which began in June last with severe general rheumatism, rendering him quite helpless, and which was complicated later by broncho-pneumonia and cardiac failure. He slowly improved after the first severe attack, and the week before his death was able to leave his bed, but he was sorely tried by the hot weather, so that his strength gave out and further cardiac attacks took place. The end came suddenly and unexpectedly.

Dr. Blandford married in 1864 Louisa, only daughter of the late Rev. George Holloway, by whom he had two sons and two daughters. His widow and all his children survive him.

Dr. Thomas Buzzard writes: "An uninterrupted friendship of some 48 years has been broken by the death of Fielding Blandford, with whom I became acquainted when he was resident medical officer at Blacklands House, Chelsea, and later was for long years more intimately associated, especially when, after his marriage, he lived in Grosvenor-street, a few doors from my house. A wise physician, eminently qualified by his quiet composure of manner and excellent judgment, to give most reassuring counsel in the branch of the profession which he distinguished, Blandford possessed besides qualities which endeared him to a large circle of friends. Perhaps a distinguishing quality in his practice as an alienist physician was his practicality. He appeared to know intuitively what were the best steps to be taken in the management of difficult and troublesome cases. Fully alive to, and regardful of, the progress of scientific medicine, to which he made no mean contributions, he was no less interested in art and music and literature. He originated, when in Grosvenor-street, a Shakespeare reading club, which used to meet periodically—mostly at his house—and which was a source of great pleasure during many years to my own and other families. The Grosvenor Musical Society, too, a gathering of amateur musicians which met alternately at the members' houses, was another institution of interest in which he took delight, and in which he was intimately associated with many now deceased whose names will be long remembered—the late Dr. Anstie, Sir J. Burdon-Sanderson, Sir J. Russell Reynolds, Lord Herschell (then a young barrister), Dr. C Bland Radcliffe, and others. In art Blandford took great interest. He was an early admirer of Whistler's work, of which, long before that artist attained celebrity, he acquired many specimens in the form of etchings. His delight, too, was in water-colour paintings, and he never failed to bring back from his travels in holiday time many sketches by his own brush. Blandford was a man upon whose sound judgment one could always rely—a staunch friend, genial in his nature and eminently companionable, as free from 'fads' as he ever was from any excitement in manner, so that his memory will always be associated, I think, in the recollection of those who enjoyed his friendship, with the idea of one who was always welcome, was never tedious, and who somehow brought with him an atmosphere of good fellowship, hopefulness, and repose."

FRANK PIERCE FOSTER, M.D. NEW YORK.

Dr. Frank P. Foster, for 31 years editor of the *New York Medical Journal* and *doyen* of the medical journalistic profession in America, died at Chadwick, N.J., on August 13th. Having suffered for the last three years, especially during 1911, from cancer of the throat, death came as a relief. Dr. Foster was born in Concord, N H., on Nov. 26th, 1841, of old New England stock, his mother being a niece of Daniel Webster, and received a thorough education at the public school of his native town. In the curriculum of the schools of New Hampshire at that time were included such studies as Latin and Greek; English was also taught thoroughly; and here Dr. Foster laid the foundation of his considerable philological knowledge. At the age of about 15 years he became a pupil of Dr. Lyman Gage, a physician of more than local celebrity, who introduced him to the study of botany, anatomy, and physiology. Thus prepared he entered the medical school of Harvard in 1857, taking his M.D. degree, however, in the College of Physicians and Surgeons, New York, in 1862. He then became an interne at the New York Hospital, where he remained for two years. He next joined as ship's surgeon a Pacific mail steamer, making a voyage through the Straits of Magellan to San Francisco. This left much time on his hands, of which he made good use by studying German, thus laying the foundation of that knowledge of the German language and literature which was subsequently so extended that in 1900 he was selected to edit, with Dr. E. Althaus, a revised edition of Adler's German and English Dictionary, which appeared in 1902. Returning *viâ* Panama in 1864, he became a contract surgeon in the United States Army, which position he held until the close of the Civil War, being for some time stationed in Baltimore. In 1865 he settled in New York, where he subsequently resided. At first he practised general medicine, but later took up as specialties dermatology, and afterwards obstetrics and gynæcology; an ingenious method of extracting the fœtus after transverse presentation now bears his name. In 1871 he introduced the manufacture of vaccine into America under the auspices of the New York Dispensary. Two years later, in 1873, he sojourned for half a year in London. Soon after his return to New York he was offered the chair of obstetrics at Yale University, which, however, he declined. During the "seventies" he held the position of librarian of the New York Hospital, a position eminently suited to his scholastic tastes.

On Jan. 1st, 1880, Dr. Foster assumed the editorship of the *New York Medical Journal*, founded in New York in 1865 by the late Surgeon-General William A. Hammond, United States Army. The *Journal* was then a monthly publication, as it had been since its foundation, and was so continued for three years, but in 1883 it became a weekly medical journal, which it has since continued to be. In July, 1900, the proprietorship of the *Journal* passed from D. Appleton and Company to the A. R. Elliott Publishing Company. In 1902 the *Journal* absorbed the *Philadelphia Medical Journal* and in 1906 the *Medical News*. In the early "eighties" Dr. Foster became editor of the well-known Encyclopædic Medical Dictionary which bears his name. It took 12 years to prepare and publish four massive volumes, and the work has been translated into seven languages. He was also the editor of a "Reference Handbook of Practical Therapeutics," in two volumes, and was on the editorial staff of the Standard Dictionary. Dr. Foster's knowledge of languages, both ancient and modern, was widely recognised during all these years. In the use of the English language he was conservative, preferring that our tongue should be left to the natural processes of evolution and not urged forcibly into novel paths by enthusiastic doctrinaires. When the American Medical Association decided upon a revision of the medical nomenclature Dr. Foster was chosen chairman of the commission and wrote the reports presented in 1909, 1910, and 1911. His editorial contributions to the *New York Medical Journal* were naturally very numerous, always excelling in their style and the correctness of their English; they referred to all branches of medicine as well as to other subjects of obvious interest to his readers. Under his wise and well-planned guidance the *Journal* acquired a leading place in American medical journalism.

Dr. Foster was also one of the 100 honorary members of the Medical Reserve Corps, United States Army, for his activities were varied and untiring. He was a strenuous supporter of the Academy of Medicine at the earliest times, when the meetings were held in the small chapel of the University of the City of New York, then situated in University-place, facing Washington-square. He also took an active part in the "code fight" in the Medical Society of the State of New York. He was a member of the Dermatological Society, which he helped to found, and of which, in later years, he became an honorary member.

Charitable in his judgment of others, willing to assist and help his friends, gladly giving from his great store of

knowledge, a master of the pen, he will be gratefully remembered by everyone who had the good fortune to become associated with him.

Mr. Kenneth W. Millican writes: "May I be permitted, as a former colleague of Dr. Foster on the *New York Medical Journal*, to add a few words of appreciation to the foregoing obituary notice? My acquaintance with Dr. Foster began at a meeting of the Mississippi Valley Medical Association at Louisville, Ky., in 1897, which resulted in his making me the offer early in 1898 to become associate editor with him of the *New York Medical Journal*, which was gladly accepted, the association continuing until 1904. I remember well the qualities as they emerged under my observation that made Dr. Foster such an admirable editor. I was first struck by his patience and gentleness when dealing with the results of inexperience in the work of the journal. He was never irritated at errors, nor did he content himself with merely pointing out the thing that was wrong and giving instruction for future guidance, but in the most patient manner he expounded the broad principles of journalism underlying the point in question. The next point was his devotion to accuracy, particularly in regard to references and to making detailed acknowledgment of anything taken from any other periodical or work. This, as he constantly insisted, was due, not only to oneself, lest one inadvertently made oneself responsible for the errors of others, and to the readers, that they might be able to fulfil the golden rule to 'verify references,' but even more to the author, who was entitled to the full credit for his work, and to the journal which was equally entitled to credit for giving it publicity. His carefulness in avoiding expressions in his own writings that might cause pain to others, and insisting on the elimination of such expressions from contributed matter, was, I am sure, widely appreciated throughout the medical profession of America. A 'pen dipped in gall' was to him an abomination. As time went on, one learnt further to appreciate his breadth of view, which led him on more than one occasion, in which subsequent events justified his judgment, to deprecate premature enthusiasm in the acceptance of novel discoveries or views, no matter how great the authority of those by whom they were sponsored. Still later one became impressed with his wide judgment of personalities in the medical profession, not only of America, but of Europe. He seemed to take a mental measure of the character and capacities of every medical man, writer or practitioner, who came into national or international prominence, and one which, so far as I was able to check it through personal acquaintance with the men in question, was nearly always correct. In like manner his estimate of the various medical periodicals, not only American but European, was keen and discriminating. I never knew him to resent honest criticism or to allow himself to be guided by bias or personal interest into unfair criticism of others. As to his scholarship, while it was undoubtedly wide, it was shown not so much in the detail he was able to carry in his memory as in his remarkable capacity for knowing instantly where to turn for such authentic information as existed on any conceivable subject, medical or otherwise, that might incidentally crop up. Dr. Foster was universally liked and respected, and he will be sincerely mourned throughout the medical profession of America."

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Otto Simon, chief surgeon of the Carlsruhe Hospital, from septic poisoning.—Dr. Albert Schinzinger, formerly extraordinary professor of surgery in Freiburg, aged 84 years. His published papers dealt chiefly with fractures and dislocations.—Dr. Paul Ziegler, *privat-docent* of surgery, in Munich.—Dr. E. Schwachten, of Berlin, chief railway surgeon of the Prussian and Hessian system.—Dr. A. Breglia, *privat-docent* of anatomy in the University of Naples.—Dr. W. Bailey, formerly professor of materia medica and therapeutics in the University of Louisville.—Dr. Henri Nicolas, formerly surgeon to the Marseilles Hospitals.—Dr. Mario Panizza, *privat-docent* of Medical Pathology in the University of Rome.—Dr. E. A. Lewis, formerly professor of anatomy in Long Island Medical College Hospital, Brooklyn.—Dr. Rava, professor of ophthalmology in the Sassari Medical School.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held in August the following candidates passed in the subjects indicated:—

Surgery.—A. E. L. Devonald (Sections I. and II.), St. George's Hospital; E. M. E. Hall (Section II.), Royal Free Hospital; G. W. B. James (Sections I. and II.), St. Mary's Hospital; J. S. H. Lewis (Section II.), University College Hospital; G. S. Richardson (Section I.), Leeds; and R. M. Wingent (Section II.), Guy's Hospital.

Medicine.—E. E. Allen (Section I.), Royal Free Hospital; G. W. B. James (Sections I. and II.), St. Mary's Hospital; R. Lamort, Bordeaux; F. G. Norbury (Section II.), Glasgow; and W. H. Watson (Section II.), Guy's Hospital.

Forensic Medicine.—A. E. L. Devonald, St. George's Hospital; G. W. B. James, St. Mary's Hospital; J. S. H. Lewis, University College Hospital; P. J. Montgomery, Middlesex Hospital; and W. H. Vincent, St. Mary's Hospital.

Midwifery.—L. K. Edmeades, Guy's Hospital; A. Fordham, University College Hospital; G. W. B. James, St. Mary's Hospital; and C. W. Jenner, London Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—A. E. L. Devonald, E. M. E. Hall, G. W. B. James, J. S. H. Lewis, and W. H. Watson.

FOREIGN UNIVERSITY INTELLIGENCE.—*Amiens:* Dr. Braillon has been appointed Professor of Clinical Medicine in succession to Dr. Bernard. Dr. Courtellement has been appointed Professor of Medical Pathology.—*Amsterdam:* Dr. F. S. Meijers has been recognised as *privat-docent* of Forensic Psychiatry.—*Angers:* Dr. Jurlais has been appointed Professor of Physiology.—*Basle:* Dr. Rudolf Stähelin of Berlin has been appointed Professor of Clinical Medicine in succession to Dr. D. Gerhardt.—*Budapest:* Dr. Körösi has been recognised as *privat-docent* of the Physiological Effect of Foods.—*Buenos Aires:* Dr. Marcelo Viñas has been appointed to the chair of Clinical Surgery.—*Florence:* Dr. Carlo Comba of Bologna has been appointed to the chair of Pædiatry, in succession to Dr. G. Mya, deceased.—*Genoa:* Dr. Augusto Ducrey of Pisa has been appointed to the chair of Dermatology, in succession to the late Dr. G. Profeta. Dr. Giuseppe Lanza of Palermo has been recognised as *privat-docent* of Pædiatry.—*Göttingen:* Dr. Reichenbach of Bonn has been appointed Professor of Hygiene and Director of the Hygiene Institute in succession to Professor E. von Esmarch, who is retiring.—*Heidelberg:* Dr. W. Gross has been recognised as *privat-docent* of Pathological Anatomy.—*Iurieff (Dorpat):* Dr. Liutkevich has been appointed Professor of Ophthalmology.—*Königsberg:* Dr. Harry Scholtz has been recognised as *privat-docent* of Medicine and Dr. W. Telemann as *privat-docent* of Medicine.—*Lemberg:* Dr. Julius Marischler, *privat-docent* of Medicine, has been granted the title of Extraordinary Professor, and Dr. Victor Felix Reis has been recognised as *privat-docent* of Ophthalmology.—*Modena:* Dr. Giuseppe Zagari of Sassari has been appointed to the chair of Clinical Medicine.—*Naples:* Dr. Aurelio Giovine has been recognised as *privat-docent* of Medical Pathology.—*New York:* Dr. John J. McPhee has been appointed to the chair of Neurology in the Post-Graduate School and Hospital.—*Padua:* Dr. Antonio Berti has been recognised as *privat-docent* of Physiology.—*Pavia:* Dr. Enrico Rossi of Naples has been recognised as *privat-docent* of Psychiatry.—*Poitiers:* Dr. Morichau-Beauchant has been appointed Professor of Medical Pathology in succession to the late Dr. Brossard.—*Rheims:* Dr. Bagnéris, *agrégé*, has been appointed Professor of Physics in succession to Dr. Chevy.—*Rome:* Dr. Giuseppe Noccioli has been recognised as *privat-docent* of Midwifery and Gynæcology. *Siena:* Dr. Antonio D'Ormea has been recognised as *privat-docent* of Psychiatry.—*St. Petersburg:* Dr. Redlish has been appointed Professor of Midwifery and Gynæcology in the Military Medical Academy, in succession to Dr. Rein.—*Vienna:* Dr. E. Pribram has been recognised as *privat-docent* of General and Experimental Pathology.

THE ROYAL SANITARY INSTITUTE.—The fifty-second course of lectures and demonstrations for sanitary officers which are held under the auspices of the Royal Sanitary Institute will commence on Monday, Sept. 18th, and will close on Friday, Dec. 1st. The lectures are for the most part given on Mondays, Wednesdays, and Fridays, but

an occasional lecture will be delivered on a Tuesday or a Thursday. The course is divided into two parts. The first part will consist of six lectures dealing with elementary physics and chemistry in relation to water, soil, air, ventilation, and meteorology. The second part will deal with meat and food inspection, including the taking of samples of water, food, and drugs for analysis. Among the lecturers will be Mr. A. Wellesley Harris, medical officer of health of Lewisham; Dr. E. Petronell Manby, medical inspector to the Local Government Board; Dr. J. Priestley, medical officer of health of Lambeth; and Dr. E. J. Steegmann. The inspections and demonstrations will be held mostly on Tuesday, Wednesday, and Saturday afternoons in September, October, and November, and will include visits to sewage works, disinfecting stations, municipal lodging-houses, dairies, and so forth. The lecture hour is 7 P.M. and the fee for the complete course is £3 3*s*. For the first part a charge of £2 12*s*. 6*d*. is made and for the second part £1 1*s*. Commencing on Oct. 6th, at 7 P.M., a course of lectures to assist school teachers and other students entering for examinations in hygiene in its bearing on school life, and for women health visitors and school nurses, will be held at the Royal Sanitary Institute and Parkes Museum. The lecturers will include Dr. Marion Hunter-Vaughan, Professor H. R. Kenwood, Dr. A. B. Kingsford, Dr. Eric Pritchard, and Dr. C. J. Thomas. The course will consist of 19 lectures and demonstrations and the fee is £1 1*s*. A course of practical training for meat inspectors will commence on Oct. 13th at 7 P.M. Full particulars of all these lectures can be obtained from the secretary of the institute, 90, Buckingham Palace-road, London, S.W.

UNIVERSITY OF LONDON, UNIVERSITY COLLEGE: DEPARTMENT OF APPLIED STATISTICS.—Application for admission to this department should be addressed to Professor Karl Pearson, University College, Gower-street, London, W.C. Professor Pearson, F.R.S., and Dr. David Heron, M.A., D.Sc., will meet students on Monday, Oct. 2nd, between the hours of 10 A.M. and 1 P.M. and 4 P.M. to 6 P.M. Lectures are given by Professor Pearson and Dr. Heron and laboratory work may be carried on in the Galton laboratory for national eugenics and in the biometric laboratory, which are both open daily from 9.30 to 5.30. A course of public lectures will also be given in the second term, full particulars of which will be announced later. Dr. Heron's lectures are given on Wednesdays and practical classes on Mondays between the hours of 4 P.M. and 5 P.M. on both days (fee: session, £6 6*s*.; term, £2 12*s*. 6*d*.) and consist of an introductory course on Statistics for those intending to take up social, medical, or eugenic problems. Professor Pearson's lectures are given on Tuesdays and Thursdays at 4 P.M. (fee: session, £6 6*s*.; term, £2 12*s*. 6*d*.), and are upon the General Theory of Statistics. This course lasts through the session, and students attending it are supposed to have had a preliminary training in mathematics. The course will discuss the whole modern theory of statistics, and illustrate its application to biometric and eugenic problems. Except under special conditions, students should be attending at the same time one or other of the laboratories for practical work. They will be taught on actual data to make statistical measurements and to calculate the various types of statistical coefficients; they will be shown the use of tables, mechanical calculators, and integrating mechanisms. The practical work will be performed on two days a week (fee: session, £3 8*s*.; term, £2 12*s*. 6*d*.). A fee, however, of £12 12*s*. per session admits to the laboratories on all days and to all lectures, as well as to the use of the library and material in the archives. Also students who come to the laboratories sufficiently trained to carry on research work of their own are admitted to the laboratories at a charge of £3 3*s*. per term, and are assisted in their investigations with material, instruments, and advice. The Galton Eugenics Laboratory contains a growing library on topics connected with eugenics, including Sir Francis Galton's own books; stored material bearing on social, physical, and hereditary conditions, including Sir Francis Galton's own anthropometric data; a collection of anthropometric and other instruments, chiefly from the Galton bequest; and an interesting historical collection of Galton portraits and other Galtoniana. There is a fine bronze bust of Sir Francis Galton by Sir George Frampton, R.A. The assistants in this laboratory are: David Heron, M.A., D.Sc., Galton research fellow; Ethel M. Elderton, Galton research scholar; Amy Barrington, computer; and Kathleen V. Ryley, assistant in pedigree-drafting. The biometric laboratory, which is assisted by a grant from the Worshipful Company of Drapers, possesses a good collection of calculating machines, integrating mechanisms, moment-finders, as well as a large series of statistical models, diagrams, and other apparatus; craniometric, anthropometric, and measuring instruments; microscopes, cameras, &c.; and a large collection of biometric and statistical memoirs. The assistants in this laboratory are: Julia Bell, M.A., Herbert G. Soper, M.A., Eveline Y. Thomson; and honorary assistant, P. F. Everitt, B.Sc., Benington student (in craniometry and anthropometry). The honorary secretary is H. Gertrude Jones.

Parliamentary Intelligence.[1]

HOUSE OF COMMONS.

WEDNESDAY, AUGUST 16TH.

Schools and Epidemics.

Mr. R. GWYNNE asked the President of the Board of Education whether his attention had been called to the spread of infectious disease, resulting in some cases in numerous deaths, consequent upon the delay in closing schools after an outbreak of disease; and whether he would consider the advisability of reverting to the former system, under which local managers were empowered to close the school upon the advice of a qualified medical practitioner.—Mr. RUNCIMAN said in reply: No such case has been brought to my notice. I shall be glad to make inquiries about any case to which the honourable Member will refer me. The answer to the last part of the question is in the negative.

Phthisis in the West of Scotland.

Mr. MACPHERSON asked the Lord Advocate whether Dr. Dittmar, Dr. Dewar, and Dr. McVail, medical inspectors of the Local Government Board, had now completed their investigations into the extent to which phthisis existed among the industrial communities in the West of Scotland; and, if so, when that report would be presented to Parliament.—Mr. URE answered: I understand that reports have been received in regard to certain localities and are now under consideration. It would be premature to make any announcement as to publication.

Post Office Medical Officers.

Sir DAVID BRYNMOR-JONES asked the President of the Board of Education whether it was the usual practice of the Board of Education to nominate for the purpose of the Elementary School Teachers (Superannuation) Act, 1898, and rules, the medical officers employed by the Post Office; and, if so, on what ground was this practice adopted.—Mr. RUNCIMAN wrote in reply: Yes; the medical officers employed by the Post Office are selected with a view to work of a character similar to that which is required of doctors nominated for the purpose of the Elementary School Teachers (Superannuation) Act, 1898. They are also conveniently distributed over the country. For these reasons it has been the usual practice of the Board, with the concurrence of the Post Office, to nominate them for the duties in question.

THURSDAY, AUGUST 17TH.

Alleged Cure for Consumption.

Mr. CHARLES BATHURST asked the President of the Local Government Board whether Dr. Kaye, medical officer of health to the West Riding county council, was requested by him to visit a maggot farm and inquire there into the alleged cure for consumption resulting from the inhalation of the substances from maggots found in putrefying meat; and, if so, what was the result of such inquiry.—Mr. BURNS replied: I have made no such request to Dr. Kaye.

Mr. BATHURST: Is the right honourable gentleman aware that it has been repeatedly stated at meetings of local authorities that he made that request?—Mr. BURNS: Yes, and I have just as repeatedly contradicted it.

Ambulance Arrangements at the Coronation.

Colonel YATE asked the Secretary of State for the Home Department whether, in view of the fact that the ambulance arrangements at the Coronation were made by the police, he would state how many members of voluntary aid detachments of the Red Cross Society did duty at the Coronation and how many members of the St. John Ambulance Brigade.—Mr. CHURCHILL replied: 2142 members of the St. John Ambulance Brigade did duty on June 22nd. The Red Cross Society offered its services, but the offer was subsequently withdrawn, as it was found impossible to ensure the attendance of a sufficient number of detachments with the requisite uniform. In consequence no members of the voluntary aid detachments of the Red Cross Society did duty.

Preserved Milk.

Mr. MOUNT asked the President of the Local Government Board whether his attention had been called to the fact that 19,000 cases of preserved mik arrived in the Port of London on Tuesday and Wednesday last; whether such milk was produced under restrictions and conditions similar to those imposed upon dairy farmers in England; and whether any tests had been made recently as to the amount of butter-fat contained in such milk, and, if so, with what result.—Mr. BURNS wrote in reply: I understand that 9000 cases of preserved milk arrived in the Port of London on Tuesday and Wednesday of last week. Examinations made during the six months ending June 30th showed that the samples tested of condensed milk made from whole milk contained an average

[1] These notes were omitted from THE LANCET last week, the issue of August 26th being the Students' Number.

of 9·76 per cent. of fat, and had been prepared from milk containing at least 3 per cent. of butter-fat. The samples of whole-milk powders contained on the average 30·1 per cent. of fat, and had been made from milk containing over 3 per cent. of butter-fat. There is no evidence to show that the sources of these imported supplies are less satisfactory from a sanitary point of view than those of home-produced milk.

FRIDAY, AUGUST 18TH.

The Nutritive Value of Bread.

Mr. CHARLES BATHURST asked the President of the Local Government Board whether, in view of the opinion expressed by Dr. J. M. Hamill in his recently published report to the Board on the nutritive value of different varieties of bread to the effect that, in the case of poor persons whose food consisted principally of bread, it was important to recognise the fact that a loaf made from households or stone-ground or standard flour possessed more available nutrient material and energy value than one made from pure white flour, he proposed to take any and, if any, what steps to bring this fact to the notice of working men and their wives throughout the country.—Mr. BURNS answered: Copies of Dr. Hamill's report have been sent to the press and will also no doubt be shortly in the hands of medical officers. I have no reason to suppose that sufficient publicity will not be secured by these means for the conclusions arrived at.

BOOKS, ETC., RECEIVED.

ADLARD AND SON, London.

National Association for the Prevention of Consumption and Other Forms of Tuberculosis. Transactions of the Annual Conference at Caxton Hall, Westminster, July 19th to 21st, 1911. Price 2*s.* 6*d.* net.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

HEALTH AND SANITATION IN ASHANTI.

ACCORDING to the report for 1910 prepared by the Acting Chief Commissioner (Mr. A. J. Philbrick) the average daily number of Europeans resident in Ashanti during the year was 258 (officials 57, missionaries 5, other non-officials 193, women 3). One official and four non-officials died, or 1·86 per cent. There are European hospitals at Coomassie (the largest town, which has a population of about 19,000) and Obuasi, and native hospitals at Coomassie, Obuasi, Sunyani, and Kintampo, while at the latter place a fly-proof building has been erected for dealing with cases of sleeping sickness. There were between 80 and 90 known cases of sleeping sickness during the year. This disease is principally prevalent in the Western Province and round Krachi. Fifteen cases were treated with atoxyl injections at Coomassie. A small special isolation hospital for the treatment of this disease is being built. Dr. Kinghorn completed his tour, and has contributed a valuable and lengthy report on this subject, which will be published. He states: "Over the whole of the Western Province sleeping sickness and tsetse flies, more particularly Glossina palpalis, are common, and both are most frequent in the semi-forest country comprising the Gaman, Berekum, and Wenchi districts. The disease appears to exist in a chronic endemic form, except possibly in the area mentioned above, though it is impossible to say it is here becoming 'epidemic.'" Mr. G. J. W. Keigwin was also stationed at Krachi on special duty connected with sleeping sickness. Small-pox was prevalent throughout Ashanti, outbreaks being reported from all parts. The provincial medical officer attributes a good deal of it to the old-established Ashanti custom of inoculating healthy persons direct from those suffering from the disease. A large amount of lymph vaccination was successfully performed (2881 vaccinations in Coomassie alone), and the outbreak is being well kept under. Medical officers were stationed at Coomassie, Obuasi, Sunyani, Kintampo, and Krachi, and a nursing sister was in charge of the Coomassie Hospital throughout the year. The report gives details of the measures being taken to improve sanitation, and the Commissioner states that during his recent tours he found a most gratifying desire on the part of the native chiefs to have their villages better laid out. The supply of clean drinking water still presents a serious difficulty. The vast majority of villages depend for their supply on running streams, which often diminish to stagnant pools for weeks together in the dry season. This water is used for all purposes, personal ablutions and the washing of clothes invariably taking place in the stream itself. In some cases the Commissioner found the water supplied for his use to be so defiled as to be useless, even after boiling and filtration. Steps are being taken to remedy this state of things.

A HOLIDAY GUIDE-BOOK.

A VERY useful guide for holiday seekers is "The Holidays: Where to Stay and What to See," published by Walter Hill, 66, Southampton-row, London, price 1*s.*, post free 1*s.* 6*d.* It contains in one volume the guides to hotels, boarding-houses, and apartments of the Midland, London and North-Western, Great Northern, Great Eastern, Great Western, and Great Central Railways. These guides contain a brief account of the principal holiday resorts on the respective routes, with numerous photographs, an alphabetical list of towns with the names, description, accommodation, terms, and so forth, of the various hotels, boarding-houses, and apartment houses. Southern Ireland, the Isle of Man, the Channel Islands, and Brittany are included. There are many railway maps, lists of golf links, and much other interesting information.

EXHIBITION OF A BABY IN AN INCUBATOR.

AT a recent inquest in the Hackney Coroner's Court upon a girl child, 7 months of age, who had died from exhaustion following diarrhœa, it was elicited that a few days after the child was born, when she was recognised as being delicate and unlikely to live, the mother had been induced to allow her to be exhibited in an incubator at the "World's Fair" at Islington. The mother stated that the infant was at the "World's Fair" for a fortnight, and that the care she there received seemed to have done her good, but that after being returned to her parent she soon became as sickly as before. From the fact that the death of the child was followed by an inquest the inference may be drawn that having received her back from the exhibitors the mother did not consider it worth while to obtain medical advice with regard to her. Otherwise a certificate of the cause of death would have been forthcoming. Here it may be observed that the mother stated at the inquest that she was paid 10*s.* a week for lending a suitable baby for exhibition, and the question may well be asked whether such exhibitions should be permitted. Ethically, the exhibition itself, if held purely for gain and for no other purpose, must be held to be indecent and undesirable

for many reasons. It could, however, hardly be interfered with legally on any ground of cruelty to a child, which might be regarded as temporarily in better surroundings than those of its home. The element of pecuniary profit to the mother seems the worst feature of the case, as it excludes the suggestion that benefit to the child was the sole object of the arrangement made.

FACTORY GIRLS' COUNTRY HOLIDAY FUND.

To the Editor of THE LANCET.

SIR,—The exceptional and long-continued hot weather is specially trying to those who have to work in large cities. The fortunate minority of Londoners who are able to get away for a real holiday—say, a whole month—will surely wish that a large proportion of their hard-worked fellow-citizens should have at least a week. Few Londoners work so hard as the women and girls, some of them mere children, employed in factories. Their average working day is nine to ten hours. The Factory Girls' Country Holiday Fund provides for these workers one precious week or fortnight of fresh air. The girls themselves begin months beforehand saving a few pence each week towards their holiday, but they cannot possibly pay the whole cost out of wages varying from 3*s.* to 14*s.* a week. We have already sent away over 4000, and hundreds more are waiting to go, but our funds are now exhausted and contributions are most urgently needed.

May we conclude by quoting from a letter received from one of these working girls:—"My friend Lizzie would like to go also as she has never been away, and the change would do her good, because she is subject to faints, and she works in a room with fifteen gas rings alight, which makes it very hot, so a change of air would be very welcome." Subscriptions and donations will be thankfully received by the chairman of the executive committee, the Rev. E. Canney, St. Peter's Rectory, Saffron-hill, London, E.C., or by the honorary secretary, Miss Paget, 28, Campden Hill-square, W.

We are, Sir, yours faithfully,

BEATRICE B. TEMPLE. NORFOLK.
LOUISE CREIGHTON. SAMUEL A. BARNETT.
WILLIAM R. GOWERS, M.D. ARTHUR B. RENDEL.
HAVERSHAM. FRANK LLOYD.

St. Peter's Rectory, Saffron-hill, London, E.C., August 26th, 1911.

PRISM BINOCULARS.

Messrs. Leitz of Oxford House, Oxford-street, W., have issued a new list of prism binoculars which contains illustrated descriptions of several new models, including a glass giving a magnification of × 4 mounted as a theatre glass; one with a magnification of × 8 with an enlarged field of view and extra stereoscopic effect; one with a magnification of × 10; and another with a magnification of × 12. The catalogue also includes a useful note on the choice of a field-glass, together with information on the optics of the subject. The name of the firm is a sufficient guarantee for the high degree of accuracy which the manufacture of prism field-glasses requires, and the improvement in glass-grinding machinery and the introduction of new metal alloys have made it possible for Messrs. Leitz to produce prism binoculars highly efficient in power and moderate in price.

A USEFUL COMPENDIUM OF NEWER DRUGS.

FOR those physicians who understand German Riedel's Berichte will prove of service as a guide to the progress that is taking place in regard to new laboratory products and other remedies. It consists of four parts, in the first of which are described the investigations and analytical work done in the laboratories of the J. D. Riedel Co.; in the second the pharmaco-therapeutic progress of 1910 is described; the third is a mentor for the names, composition, qualities, and uses of the newer remedies, specialities, and technica products; while the last gives a list of the special preparations of the firm. A tabular appendix gives the specific gravities of a large number of liquids contained in the last German Pharmacopœia. The alphabetical order is followed throughout the work, thus making reference easy, while the detailed information as to doses and uses of the various preparations is reinforced by ample references to the literature. Those of our readers who may desire a copy should apply to the J. D. Riedel Co., 54, Cannon-street, London, E.C.

Annoyed must be perfectly certain of his facts before making the complaint. For example, he must not state that the druggist had not a certain preparation in stock unless he can prove it. But if he is sure of his ground, he is advised to complain to the Pharmaceutical Society who would certainly recognise that such proceedings are wrong and would, we believe, remonstrate with their member.

R.N. (*? Portsmouth*).—Our correspondent has not enclosed for our private information his name and address with his interesting letter.

G. C. W.—As far as the medical profession is concerned it seems to us that the course advocated is now too late.

Assistant Physician.—Very good, but, alas, it has appeared before.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for September, 1911:—

April-October.—Rome Exhibition (United Italy's Jubilee).
,, 29th-Oct. 26th (Turin).—International Exhibition.
May 3rd-Oct. 31st (Glasgow).—Scottish Exhibition.
,, 6th-Oct. 31st (Dresden).—International Hygiene Exhibition (British Section opens June 14th).
May 12th-Oct. 31st (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
May 18th-October 31st (London, Shepherd's Bush).—Coronation Exhibition.
,, 19th-Oct. 31st (London).—Earl's Court Exhibition.
August 28th-Sept. 11th (South-East of France).—Eleventh "Voyage d'Etudes Médicales."
,, 30th-Sept. 2nd (Berlin).—Third International Laryngo-Rhinological Congress.
,, 30th-Sept. 6th (Portsmouth).—British Association.
Sept. 2nd-9th (London).—Bakers' and Confectioners' Exhibition.
,, 4th-9th (Yarmouth).—Sanitary Inspectors' Association. Annual Conference.
,, 5th-7th (Philadelphia).—American Electro-therapeutic Association.
,, 9th-11th (Ostend).—Fifteenth Flemish Nature and Medical Congress.
,, 11th-13th (Vienna).—German Urological Society.
,, 11th-13th (Berlin).—Third International Conference on Infantile Mortality (*Gouttes de Lait*).
,, 11th-16th (The Hague).—Thirteenth International Congress on Alcoholism.
,, 12th-15th.—Celebration of the 500th Anniversary of the Foundation of the University of St. Andrews.
,, 18th-23rd (Sydney).—Australasian Medical Congress.
,, 18th-23rd (Paris).—International Conferences of Genetics.
,, 23rd-Oct. 21st (London, Olympia).—Electrical Exhibition.
,, 24th-30th (Karlsruhe).—Eighty-third Meeting of German Physicists and Physicians.
,, 26th-28th (Louisville, Ky.).—American Association of Obstetricians and Gynecologists.
,, 26th-30th (Brussels).—Third Congress of the International Society of Surgery and Exhibition of Fractures.
,, 28th-30th (Dresden).—International Congress for the Protection of Mothers and Sexual Reform.
,, 29th (Edinburgh).—Association of Veterinary Officers of Health. Annual Meeting.
,, 30th (Bruges).—Sixth Belgian Congress of Neurology and Psychiatry.
September (Genoa).—International Exhibition Marine Hygiene.
,, (Turin).—Congress of the Association of Italian Railway Physicians.
,, (Manchester).—Second Conference of the British Hospitals Association.
September-November (Antwerp).—International Exhibition of Alimentation, Brewing, Wines, and Liqueurs.

Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women.
THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON), Clinical Theatre, London Hospital, Mile End-road, E.
MONDAY.—2 P.M., Demonstration in Clinical Medicine:—Dr. Wall: Pulmonary Diseases.
TUESDAY.—2 P.M., Demonstration in Clinical Medicine:—Dr. Grünbaum: Diseases giving rise to Morbid Renal Excretion.
THURSDAY.—2 P.M., Demonstration in Clinical Medicine:—Dr. Head: Diseases of the Nervous System.
FRIDAY.—2 P.M., Demonstration in Clinical Medicine:—Dr. L. Smith: Diseases of the Heart.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (4th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (5th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (6th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's 2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. THURSDAY (7th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (8th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.)., Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (9th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1911, which was completed with the issue of June 24th, were given in THE LANCET of July 1st.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1911 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

An Address

ON

SURGICAL GASTRIC DISORDERS, THEIR TREATMENT AND RESULTS.

Delivered before the Blackburn Medical Society

BY E. STANMORE BISHOP, F.R.C.S. ENG.,

SURGEON, ANCOATS HOSPITAL AND JEWISH MEMORIAL HOSPITAL, MANCHESTER; PRESIDENT, MANCHESTER MEDICAL SOCIETY.

MR. PRESIDENT AND GENTLEMEN,—The word "dyspeptic" connotes not merely some defect in the ordinary process of digestion, but also a gloomy outlook on life, whilst "eupeptic" is synonymous with all that is happy, light-hearted, and gay. Such a correlation of ideas suggests a very close relationship, and emphasises to us, as medical men, the importance of a close study of all anomalies of the alimentary tract, and especially those which affect the primary segments, the stomach and duodenum. It is not merely life, but the *joie de vivre*, that which makes life worth living, which is more readily influenced by them than by diseases of almost any other organ.

Until the last 30 years the treatment of such diseases has been almost exclusively the province of the physician, gastro-enterostomy, the operation which has done so much to show the efficiency of surgical means, being first performed in 1881. Before this, surgical effort had been mainly directed against cancer of the stomach, and, as the surgeon was then usually called in only in the later and more hopeless stages of that disease, with extremely unsatisfactory results. But rapidly increasing experience from that time showed that there were many comparatively benign and some immediately dangerous states in which surgery could render important service, cutting short what had previously been believed to be essentially chronic disease, preventing in many cases what had been considered inevitable results, and rescuing from imminent death patients who in earlier times would have been perforce left to a painful but unavoidably fatal issue. It is to those conditions that I ask your attention.

Surgical procedures are to-day utilised in six distinct phases of gastric and duodenal disease:—(1) Perforation of gastric or duodenal ulcers; (2) acute or chronic gastric or duodenal ulcer during its course before perforation; (3) gastrectasia due to pyloric obstruction consequent upon cicatrisation of ulcers at or near the pylorus; (4) hour-glass stomach (bilocular, trilocular, &c.) also due to cicatrisation of ulcers in other parts of the stomach; (5) adhesions around old lesions dragging upon or compressing portions of the upper digestive tract; and (6) gastric carcinoma.

In the consideration of these various conditions I do not propose to make any feature of statistics, which are dry, uninteresting, and often misleading, since cases, although grouped under one name, very often resemble one another in but little else, but briefly to indicate their several points, followed by one or two illustrative cases, and to suggest the conclusions which they appear to indicate.

ACUTE ULCERS.

And first as to perforation of gastric or duodenal ulcers. With very short warning in the way of some discomfort after meals for a few weeks, the subject of this cataclysmic occurrence is suddenly struck down by intense pain in or near the epigastrium, which gradually subsides, or is cut short by morphia. Very soon, however, the pain returns, spreads over the umbilical region, or, if duodenal, down the right side of the abdomen, becoming more and more diffused over the entire area, and accompanied by rigidity at first of the upper recti, later of all the abdominal muscles. If left still longer rigidity disappears, peristalsis ceases, the abdomen becomes rapidly distended, and in the majority of cases, unless relieved by surgical means, death follows. I shall, however, later narrate a case in which undoubted perforation of the stomach occurred, as proved by an operation ten months after, which recovered sufficiently for the man to resume work under purely medical treatment.

Illustrative Cases.

At present I offer for your consideration two cases which illustrate, the one gastric, the other duodenal, perforation:—

CASE 1.—A man, aged 37, was admitted to Ancoats Hospital in March, 1909. On the morning of admission he considered himself in fairly good health; afterwards he admitted to one week's sensation of some pain after food, later to some hazy "few weeks." He ate a good breakfast at 7.15 A.M., and felt no pain after it. He continued at business until 5.30 P.M., having dined at mid-day off stewed steak and potatoes. He was washing himself previous to departure when something was felt to give way suddenly in the epigastrium. No immediate pain was felt, but there was a sensation of rapidly increasing weakness. As he walked with difficulty down a long room he became faint and short of breath. Half an hour later severe pain began in the upper abdomen, which became steadily worse until, he said, it amounted to agony one and a half hours later. He vomited once; the fluid rejected contained food, but no blood. Morphine was injected; relieved by this he was able to be removed to the hospital.

On examination there, great tenderness, increased by pressure, was found over the entire epigastric region, and there was rigidity of both upper recti, the lower segments being still supple. His temperature had fallen to 96·8° F., his pulse to 66, but his respiration was quickened to 36. He was not at that time in any great pain

The abdomen was opened five hours after the initial lesion. When the peritoneum was divided, gastric contents at once escaped and poured out in great quantity. When sufficient had been removed by sponges the stomach was drawn forward and a round punched-out opening was found surrounded by an area presenting a whitened, bleached appearance which faded away gradually into the normal colour of the stomach wall; the tissues were not thickened or indurated. The opening was closed by two superposed purse-string sutures, and after drainage had been arranged for the abdomen was closed.

This is an almost typical picture of the perforation of a gastric ulcer; and that of a duodenal is similar with some few modifications.

CASE 2.—A young girl, aged 19, was at work as a mule-tenter, when suddenly without any warning, about 4 P.M., she was attacked by violent pain in the epigastrium, bringing her to the ground. After a few minutes it became less intense, at the same time sinking to the umbilical level. After resting about half an hour she *walked* some 150 yards to the hospital. When examined the pain was so much less that she could with difficulty be induced to remain, but as both upper recti, and especially the right, were found to be rigid and there was general tenderness all over the epigastrium a diagnosis of perforated duodenal ulcer was made. The abdomen was opened four hours after the first appearance of pain and a pinhole perforation was found on the anterior duodenal wall from which fluid was issuing. The opening was closed and the patient recovered. Later, inquiry elicited a history of mild epigastric pain lasting for a month or two, beginning an hour after food and relieved by vomiting or by taking more food.

I requested my house surgeon, Mr. G. N. Braham, to write to as many as possible of these cases in order to obtain final results, and the reply from this one, I think, merits reproduction. She writes: "I am pleased to let you know that ..... since I have been improving in health I am going on the adventurous errand of going to be married. I now make a special thanks on behalf of my intended husband for the good you done to me so that we can be linked in wedlock." (Jan. 24th, 1911.)

Diagnosis.

The very short history in both these cases will be noticed, which no after inquiry during convalescence could shake; the sudden onset, in both some hours after food had been taken. These cases have been chosen mainly because they illustrate the two forms that onset may take, not at all as characteristic of any difference between the two *positions* of the ulcer, since in both the first symptom occurred some time after food, and the objective signs were much the same—but in order to show that occasionally pain is not the initial symptom. The first symptom in the first case was not pain—that did not become marked for at least half an hour—but there was a definite sensation of something having given way and this was followed—before the pain—by a sensation of increasing weakness.

On admission, in both cases the initial pain had much decreased—in the one case after a hypodermic injection of morphia, but without it in the other. Both patients were somewhat surprised at being told that an immediate operation was necessary. This is not uncommon, and a medical man seeing them for the first time during this period might easily be misled as to the gravity of their condition. The points of importance, those upon which the diagnosis was based, however, were the conjunction of three signs, and especially the presence of a fourth. The three conjoined signs were: low temperature, rapid pulse, and increased rapidity—and shallowness—of respiration. These alone with the history might simply mean shock, due to unusually severe colic, renal, biliary, or intestinal, or to some mental or other cause unknown. The presence of the fourth, rigidity of the upper recti, was, however, conclusive. This rigidity was marked, local, and persistent.

Value of Abdominal Rigidity as an Early Sign.

Perhaps I may be excused if I enlarge a little upon the importance of this sign in connexion with the vitally important early diagnosis, since it has been received with incredulity by some writers and a sort of contemptuous indifference by others. It is said by some to depend on "peritonism," a term of which no satisfactory definition has ever been given; in every case in which it occurs, however, it has marked the first stage of what will, if left alone, ultimately develop into undoubted peritonitis, and it therefore seems far more reasonable to consider it as marking the incipient stage of that inflammation.

For many years I have suggested the analogy between inflammation of this great serous cavity and that of other serous cavities, such as those of the joints. In acute inflammation of a joint the first and automatic sign is rigidity of the muscles which move that joint; this is recognised by the fixation of the bones acted upon by these muscles, and is known as Hilton's sign, since it was first described by that surgeon in his famous, though I fear now somewhat forgotten, book, "Rest and Pain."

The eye is another joint subject to the same law, and is peculiarly interesting, since it is, so to speak, split open naturally, so that we can see for ourselves the various changes taking place in it during the progress of the morbid state. Here, too, the first effect is the automatic contraction of the muscles entering into its composition, the orbiculares palpebrarum.

In inflammation of the abdominal serous cavity the first sign is similarly rigidity of the muscles acting upon the tissues which form the abdominal joint,[1] but in this case the rigidity of the external muscles themselves is the most easily recognisable; if the inflammation is general, all the muscles are affected; if partial, only those muscles or portions of muscles which are in connexion with the patch of inflamed peritoneum.

(Ordinarily we speak of each rectus muscle as a single muscle; but above the umbilicus each is really divided into three, not including the portion below this point. There seems reason to think that under pathological conditions each segment may act individually and as a distinct muscle.)

I have said that if the inflammation is general all the muscles are affected, and that does not mean merely those of the abdominal wall. It includes also the muscular coats of the intestines themselves. As a necessary consequence the normal movements of these muscles, peristalsis, ceases also, and therefore in the majority of cases there is, coincidently, obstinate constipation. But such coincident action naturally presupposes an antecedently perfect mechanism, and therefore this rigidity is most marked in these acute cases where perforation suddenly brings direct irritation to bear upon a previously healthy peritoneum. This automatic rigidity, the first and most trustworthy sign of acute peritonitis, does not, however, last very long, for the intestinal tube, especially the portion near the ileo-cæcal valve, contains a multitude of organisms, harmless enough in health, but which, when the conditions under which they exist in the body are materially altered, as they are in inflammatory states, become lethal and form poisons which derange that mechanism. Such derangement will result in the loss of rigidity and the occurrence of diarrhœa. The sign, therefore, is not, and cannot be, of long duration—it is not seen at all in chronic inflammations—but in the early stages of acute peritonitis it is always present and is to be entirely relied upon. Conversely, its absence is equally sound proof that acute peritonitis is not present. It must, however, be genuine rigidity and not the merely protective contraction due to fear of rough handling or the contact of a cold hand; such contraction will disappear rapidly if the examiner's hand is warm—and gentle; true rigidity will not.

Incidentally this symptom may be trusted to differentiate between colic of all kinds and peritonitis. In colic the irritant material, though its presence may be associated with quite as much pain, does not come in contact with the peritoneum, and therefore no actual rigidity is produced; in acute peritonitis there is actual contact between the irritating material, whatever it may be, and the peritoneal membrane, and rigidity is the result. This was well illustrated in a case sent to the hospital some few months since by an extremely smart practitioner who, however, has not yet shaken himself free of the old teaching as to peritonitis; curiously enough, his view was shared by a "medical" consultant whom he had called in before bringing his patient, as he did, in his own motor several miles for immediate operation. The history given was that the day before the patient, a woman, had been attacked by severe pain and vomiting, which had continued during the night and had been associated with constipation. During the journey she had another severe paroxysm of pain, and her medical attendant felt certain, as he told me, that she had commencing peritonitis. On examination, however, the abdomen was flaccid and no rigidity could anywhere be found. Depending upon the absence of this sign, though its significance was confirmed by the character of the pulse and the appearance of the face, but mainly upon this, the reliability of which I have so often verified, operation was decided against, and four or five days later the patient returned home well. In these days, when the necessity of early diagnosis is so much and so advisedly insisted upon, there is, perhaps, a risk of seeing "peritonitis" too frequently, and it is well to have a symptom, upon the presence or absence of which one can safely depend, to settle this question, especially as it is in these sudden acute cases that it appears most automatically.

CHRONIC ULCERS.

So much for acute ulceration. These cases are, however, rare as compared with those of the chronic type, which are of supreme interest at the present time. Here are specimens of some of the most usual forms seen. The points worth note are—

Various Types.

1. The *terracing* of these ulcers (Fig. 1). It is now generally believed that a chronic ulcer commences by the detachment of the mucosa over a small area from the nutritive tissues below by some material, gumma, tubercle, or simple clot produced by the rupture of a blood-vessel, which separates it from its ordinary blood-supply. The mucosa so detached necroses and is cast off as a slough or is digested, thus opening the way for gastric juice to act upon the unprotected tissues beneath. These may later become to some extent protected by the abundant mucus

FIG. 1.

Terraced chronic gastric ulcer.

[1] The word "joint" is usually associated with the presence of bone and cartilage, but these are by no means essential elements. The essentials of a joint are, first, two surfaces capable of movement upon each other; secondly, a lining membrane secreting a fluid which renders such movement easy and painless; thirdly, muscles capable of actuating such movement; and, fourthly, a reflex nerve arc, through which afferent impulses coming from these surfaces pass to a spinal centre and excite efferent impulses actuating the muscles which bring about such movement. The abdominal cavity is precisely such a "joint."

FIG. 2.

Peritoneal aspect of a perforated chronic gastric ulcer.

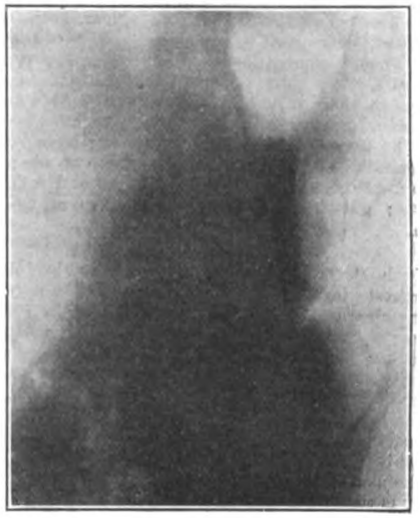
FIG. 3.

Mucous aspect of same ulcer as in Fig 2.

FIG. 4.

"Saddle" ulcer, with perforation in right-hand corner.

FIG. 5.



X-Ray photograph of dilated atonic stomach. Note the air chamber above. The fundus, which is not well shown, but which could be clearly seen in the negative, lies immediately above the pubis.

FIG. 6.

Atonic dilated stomach due to carcinoma of the pylorus. The gastric wall was so thin in parts as to show the black background through.

FIG. 7.

Recurrent ulcer after excision and reunion of walls. Note position of the (originally) external thread. (By courtesy of Dr. Andrewes, St. Bartholomew's Hospital.)

secreted by the sympathetically irritated glands around, or, as Katzenstein has shown, by the production of an increasing antiferment which neutralises the action of the pepsin present. Whatever be the reason, the digesting agent appears to act with less and less ease as it penetrates more deeply, and the ulcer sides are therefore not cleanly cut, but descend in steps which are well shown in this and other cases.

2. The peritoneal coat resists most strongly and may be extensively bared before it yields at some small point, as in Fig. 2.

3. Frequently during the process some small vessel is eaten into and copious hæmatemesis may be the result, or if perforation also occurs the abdomen may be full of blood mixed with gastric contents.

4. The greatly contrasted extent of the lesion consequent upon this within and without the stomach is well seen in the photograph of the same ulcer seen from the interior of the stomach (Fig. 3).

5. The peculiar shape affected by ulcers along the lesser curvature. These are specially suggestive of hæmorrhagic origin. As is well known, the coronary artery running along this curvature gives off numerous branches which run at right angles to it. If one of these gave way and a clot were formed, it also would lie in the same direction, would be of greatest volume near the origin of the vessel, and taper outwards towards its extremity. Fig. 4 shows such an ulcer extending outwards on both anterior and posterior walls from a common centre in the lesser curvature. Such an ulcer has been called a "saddle" ulcer, both from its shape and because it seems to bestride this edge of the stomach.

6. Though single ulcers are, at least in my own experience, the rule, they may be multiple. In such a case various stages in their formation may be studied on the same preparation. An ulcer which has only reached an early stage may be unrecognisable from without; were surgical interference limited to excision or inversion of the more marked lesion, the other would still enlarge and might later perforate; gastro-enterostomy alone favours the healing of both.

Previous History.

Much stress has been laid, and justly laid, upon the anamnesis in the question of diagnosis, but patients differ in the clearness of their statements and in their power of giving a correct or even connected story; much tact and great patience are often required, therefore, as well as a definite idea on the part of the examiner as to the relative value of the various points which he may elicit. Some confusion has arisen because it has been difficult to separate the essential symptoms from those dependent upon later changes, but this is gradually disappearing.

The usual history of a patient possessing a chronic gastric ulcer is that of a series of attacks of epigastric pain coming on at a more or less definite time after food. The patient may be of either sex. Usually the age at which a medical man is consulted is that of middle or advanced life, and the impression patients usually apparently wish to convey is that the history of their complaint is but a short one. On more careful inquiry, however, it will be found that they are only speaking of their last attack, which may have been somewhat more severe than those previously experienced; they will, if pressed, admit that for years they have suffered from discomfort after food with periods between of perfect freedom—a freedom in some cases so complete that it is difficult for them to realise that any connexion exists. No satisfactory explanation has yet been given for these periods of freedom from active symptoms, unless it is to be found in Bolton's experiments on dogs, and to be coincident with actual healing of ulcers situated in regions where their cicatrisation does not interfere with free evacuation through the pylorus. Bolton produced actual gastric ulcers and showed that when once the sloughing stage was complete and the slough had separated, so long as there was no obstacle to free evacuation of the stomach contents, there was a natural tendency for such ulcers not merely to heal, but for their bases to become covered once more with normal mucosa in which normal gastric glands were again present. If, however, they involved the pylorus, and consequently attempts at cicatrisation tended to obstruct that orifice, healing did not take place. These intermissions are an integral fact in the diagnosis; the same symptoms in a person of middle or advanced life, with no history of previous isolated attacks, are far more suggestive of commencing carcinoma than they would be were such a history obtainable.

Picture of Attacks.

The descriptions given of such attacks vary necessarily. Not only will an ulcer on the lesser curvature produce a different picture from that of one at or near the pylorus, but in the same case there will be differences at different times owing to the presence or absence of adhesions around. In the earlier attacks such adhesions will not be present; in later ones they are frequently to be found, uniting the stomach to liver, pancreas, omentum, gall-bladder, or transverse colon, and, by the drag exerted by their contraction upon these, adding new and non-essential symptoms which may overshadow those characteristic of the gastric lesion.

The characteristic picture, that of the earlier attacks, is the following. There is epigastric discomfort, weight, sense of distension, sometimes actual pain, occurring at a more or less definite time after the taking of food, usually from three-quarters of an hour to two hours after. This serves to distinguish between gastric ulcer and cholelithiasis, in which condition also the taking of food may induce discomfort, but in this latter, malaise arises during the actual meal, which is in consequence often left unfinished. In addition, breathlessness, even asthma after or towards the end of a meal is not uncommon in conjunction with the cholecystitis accompanying biliary calculi; unless adhesions exist between the gall-bladder and the stomach, this does not seem to occur in gastric ulcer.

In gastric ulcer there is freedom from pain directly after food; this is perhaps the time when the patient is most comfortable. The appetite for food is not impaired, thus distinguishing from gastric catarrh or succurrhœa. There is a good appetite, though often enough, warned by previous experience of its later effects, the patient has conceived the idea that certain articles of diet are more harmful than others, or that a full meal is productive of more pain than a restricted one, and he will in consequence eat but a small amount at any one time and carefully avoid certain kinds of food, thus giving the impression that his appetite is at fault.

The time at which pain or discomfort will come on after food will vary with the position of the ulcer; it will occur earlier if the lesion is in the cardiac area, later if near the pylorus. Indeed, when situated at this point, it is almost impossible to differentiate from duodenal ulcer by this test of time alone. It was believed that duodenal pain was felt at, and after, the moment when, digestion having reached a certain point, the pylorus opened and the acid gastric contents were allowed to pass, but Hertz showed by means of the Roentgen rays that food had already been passing into the duodenum for some time before the duodenal pain began. Such pain, therefore, must depend rather upon the degree of acridity of the material passing than upon its mere contact. So far as time is concerned, a safer point upon which to rely for the diagnosis of duodenal ulcer is the occurrence of early morning pain; pain, that is, which wakens its victim and is best allayed by the taking of food, biscuits or thin bread-and-butter. This appears to be characteristic of duodenal irritation and is not observed in the purely gastric variety. It may, however, occur in simple duodenal catarrh.

The ultimate diagnosis between such cases will be made after careful tests of gastric contents and of fæces, remembering especially those for occult blood. Radiographic observations are also of much utility, since they throw light upon the motility, tone, and irritability of the gastric or duodenal walls, the patency or otherwise of the pylorus, and the prospects of success after operation.

Progress of the Ulceration.

The further progress of such ulceration appears to lie in one of four directions: either towards healing, if the pylorus is open, and the patient is placed under efficient medical direction, or towards late perforation on the one hand and gastrectasia following contraction of the scar, if near the pylorus, or bilocular stomach, if the scar is farther away, on the other. The fourth is the imminent danger of carcinoma implanted upon such a scar, the most distressing result of all. And this danger of carcinoma is by no means rare. Sonnischen found 14 per cent. of 156 cases of gastric cancer examined post mortem in the Pathological Institute at Kiel undoubtedly

developed from ulcer, whilst in a second series Klausa found 26 per cent. Stich declares that ulcer carcinoma constitutes 30 per cent. of gastric cancer. Mayo found 54 per cent. of the cases of gastric cancer at Rochester in which both the clinical history and pathological examination made it certain that they had originated in ulceration, whilst Robson reports no less than 59·3 per cent. of his cases of cancer as giving a previous history of chronic ulcer.

Healing of an ulcer may occur, and probably does occur, in all prolonged cases from time to time. The characteristic intervals between the several attacks are distinctly suggestive of this, but such healing is not necessarily followed by cessation of the symptoms. The following case, to which I have already referred, is evidence of this :—

CASE 3.—The patient, a male, aged 59, was admitted in November, 1907. For two years this man had suffered from epigastric pain two hours after food with occasional vomiting. Several times the vomitus had contained material like coffee-grounds. Twelve months previous to admission a very sudden and severe attack of abdominal pain came on some little time after his return to work from dinner. He became collapsed and remained in that state for some hours. He was taken home, kept in bed, and treated medically. After several weeks' illness he recovered sufficiently to do some work, but was never well. At the time of admission he said that he felt most comfortable in the morning, though he had no appetite for breakfast. Two hours after dinner, which he enjoyed, a feeling of distension with dull aching pain was felt and lasted all the afternoon.

The abdomen was opened. On the anterior wall of the stomach was a thickened, puckered area, with the appearance of scar tissue. To the centre of this a patch of omentum was firmly adherent. The posterior no-loop operation was done and recovery was rapid and perfect; there was no further pain, distension, eructations, or vomiting. He writes now, more than three years later :—"I am in splendidhealth, never better in my life. I have never had any return of the vomiting or the slightest pain after eating, and can eat anything without having to suffer the slightest discomfort and can eat a supper and have a good night's sleep after—a thing I could not do for years before the operation. *Now* life is worth living, *before* the operation it was one long misery ..... so you will see from the above that I have derived immense benefit, and if it had not been for it I feel sure I should not have been here to-day."

Late perforation of a chronic ulcer will sometimes be found. In such cases there is frequently some leakage for a while before the full yielding of the gastric wall. If the ulcer be situated anteriorly, and the amount lost at any one time be small, around the point of exit adhesions may form, aided by the efforts of that policeman of the peritoneal cavity, the omentum, which, as in the last case, may close it again, but the escaped fluid may also induce slight pelvic peritonitis, otherwise not to be accounted for. Last year Dr. A. W. W. Lea of Manchester recorded three such cases in women, and I have myself seen four which appeared only explicable on some such hypothesis. If the lesion is on the upper or posterior surface, subhepatic or subdiaphragmatic abscess may be produced. In other cases when the opening is large practically the same symptoms may be seen as in the perforation of acute ulcers, but the history obtainable is a far longer one, and will probably include large losses of blood by vomiting.

Advantages of Gastro-enterostomy done at First Operation.

The treatment by immediate laparotomy followed by closure of the gap is, of course, obvious. Mere closure may at the time be all that is practicable. The state of such patients is such that surgical interference must be reduced to the minimum which is at the moment sufficient. But, if possible, gastro-enterostomy should also be done at the same time. If possible, because closure of the ulcer, if it is to be effective, may interfere so greatly should the ulcer be in the pyloric area—the most probable area—with the onward passage of food that acute dilatation and death may follow rapidly, or should the patient escape this his vitality may be so reduced by the abstention of food by the mouth or by the alternative vomiting produced by the attempt to take it that he may not be able to bear any future interference.

Such a case was seen in conjunction with my friend, Dr. T. B. Riddall of Longsight, in April last year. The patient, a male, 56 years of age, gave a long history of stomach ulcer, culminating, on the morning he was seen, in sudden perforation. Without delay he was removed to a surgical home and laparotomy performed about 12 hours after. A widely open gap was found in the pyloric area, through which much material had passed, and the peritoneum was pretty full; this took a little time to remove, which, added to the time expended in careful suture, seemed to be as much as he was fit to bear. The abdomen was therefore closed, and the gastro-enterostomy, which was evidently required, postponed until a later date. Rectal feeding, with proctoclysis was at once started, but after three days the rectum became irritable and refused to retain anything. Tentative feeding by the mouth was substituted, but this gave much discomfort, only relieved by vomiting, which still further exhausted the patient; it was evident after a day or two that food could not pass through the much constricted pylorus, and that, unless another exit was provided, the patient would die from starvation. Up to this time, but for the difficulty of alimentation, progress had been satisfactory; there was no peritonitis; respiration, pulse, and temperature were all normal, and there seemed no reason to think that he would die, if we could but feed him. On the seventh day, therefore, gastro-enterostomy was done. The peritoneum was healthy; indeed, it was curious to see how quickly, after so much irritation, it had returned to a normal condition; but although food was now taken and retained, the shock of the second operation was too great, and he died 24 hours later from pure asthenia.

Gastrectasia.

Gastrectasia is not an uncommon result of pyloric contraction due to the scarring of an ulcer in this region Here is an X ray photo (Fig. 5) of such a dilated and atonic stomach. Above, the usual air-chamber is clearly seen, immediately below the diaphragm, whilst the fundus reaches almost to the pubic arch. Also an ordinary photograph (Fig. 6) of a portion of a dilated stomach, in which the extreme tenuity of its walls sometimes attained may be appreciated. In this case cancer had followed ulceration and the obstruction had been prolonged, and such an amount of thinning is unusual, but it is not seldom approached. The most important consideration which these two illustrations demonstrate is that a stomach which shows signs of dilatation should not be left too long, since any operative interference would be useless in such cases. The tone of the gastric walls, once lost, does not appear to be regained, and operation, however well planned and carried out, would necessarily fail.

Bilocular Stomach.

Bilocular stomach is the result of contraction of the scar of an ulcer seated astride the lesser curvature—a rather favourite site for a chronic ulcer. I have shown a well-marked specimen of this. As this ulcer heals it pulls the greater curvature nearer and nearer to the lesser at its own plane until the cavity may be almost divided into two pouches, connected only by a narrow tube lying just below the lesser curvature. The symptoms produced by this condition are well known; I merely wish to draw attention to the help rendered by radiography in adding certitude to the suspicions aroused by them. The patient was a woman, 33 years of age, and had complained of intermittent attacks of vomiting for eight years, with pain coming on at various periods after food. Radiography demonstrated most clearly the separation of the stomach into two pouches. She was operated upon in January, 1909, both gastro-gastrostomy and gastro-enterostomy being done. She writes now: "Just at first, after leaving hospital, I used to have often returns of the sickness, but for the last twelve months I feel better than I have ever done in all my life. I am now feeling strong and well and eat most things in reason. ..... I returned to my work in May after the operation, and with the exception of a week for a bad cold and a few days through being run down, I have not had a day off since; before I could never keep up more than three months at a time."

But X ray photographs sometimes suggest bilocular stomach when such a condition does not really exist. Such an appearance is usually due to spasm of the transverse band which marks off the cardiac from the pyloric area and may be due to an ulcer on the lesser curvature, but is strongly suggestive of appendicular disease which by reflex action may produce symptoms very difficult to distinguish from those due to gastric or duodenal ulceration. Besides such X ray appearances, perhaps the most useful guide is to be found in the fact that vomiting in the cases of gastric lesion always gives relief, whilst it has no effect in those in which the lesion is appendicular. I have lately published two cases referred to me as cases of gastric ulcer, in which, on operation, no sign of any lesion could be found in either stomach or duodenum, but in both of which well-marked appendicular chronic inflammation was present. Moynihan

was the first, I believe, to note this fact, and has himself given details of several instances.

Results of Operation.

It is, however, in cases of gastric or duodenal ulcer, before dilatation to any marked extent, or the implantation of cancer has complicated matters, that the best results from operation are obtained. Curiously enough, it appears to be an advantage if the lesion is situated, as it so often is, in or near the pylorus, and that opening is becoming obstructed by scarring. The most brilliant results are seen in such cases, so much so, that certain operators have advocated and practised the closure of this orifice by suture or ligature in cases where the ulcer was in a different situation. Frequently with a pyloric or duodenal ulcer inversion or excision of the diseased area will result in practical occlusion of the normal passage. That does not matter if gastro-enterostomy is done, as the new stoma prevents any accumulation of contents, but I doubt if an artificially produced occlusion is indicated. Mucous surfaces will never adhere, however closely they are opposed, and sutures or ligatures in the intestinal tract tend invariably to make their way into the lumen of the gut to which they are applied. This was known as early as the days of Travers, but some believed that this tendency was attributable to the septic character of the sutures then used, and that it would not occur if the suture were sterile.

I am able, by the courtesy of Dr. F. W. Andrewes, of St. Bartholomew's Hospital, to show a photograph (Fig. 7) taken after excision of a chronic ulcer in which the internal suture—of gut—has disappeared and the outer suture—of aseptic silk—has slowly worked through in the classic fashion until it now, knot and all, is lying almost loose in the interior of the stomach. This figure is very instructive for other reasons. It shows the uselessness of catgut for the mucosal surface. The edges of the mucous membrane at the line of union have parted, the gut having been digested too soon, and contact of the gastric juice with the deeper layers has thus been permitted, in consequence of which a second ulcer has been produced by its action. It also gives some data as to the time required for the formation of such an ulcer, since three months elapsed between the time of excision and the post-mortem examination at which this was found, but above all I think it shows the uselessness of applying any ligature to the pylorus, the effect of which can only last as long as the ligature exerts its mechanical pressure outside the gut.

One reason for this proposed closure of the pylorus is the fact that the contents of all tubes in the body tend to make their way, if they possibly can, through the natural channel in preference to any artificial opening; whilst any spasm or temporary constriction of such a channel, if it can obtain rest for a time, tends to pass away. A good illustration of this is seen after perineal section for urethral stricture; at first all urine escapes through the new opening, but later, even if nothing is done in the way of dilatation, the stricture dilates, the spasm which has accentuated it passes away, and urine in larger and larger quantity comes through the urethra, less and less by the artificial opening, even though this is apparently the more easy and direct route. This appears to be a natural law, and obtains also with the artificial stoma produced by gastro-enterostomy. Those who look upon this operation as only of use if it can be made permanent naturally wish to prevent this, though they fail, and I think are bound to fail, for the reasons stated. But that does not diminish the usefulness of, nor the necessity for, the operation. In those cases of organic stricture at the pylorus, where the necessity for a permanent opening exists, the new stoma will remain open; in those where the constriction is temporary, due to spasm produced by an ulcer at a distance from this valve, but equally requiring relief at the time, the natural passage will again become free, and the stoma possibly close, but this will not happen until the ulcer has healed and the irritation caused by its presence has disappeared. A tracing on the radiographic screen taken six months after the operation shows that food is once more passing through the pylorus, though still some finds its way through the new stoma.

The "Modern" Operation of Gastro-enterostomy.

The reputation of gastro-enterostomy as now performed has suffered greatly from the results of the earlier attempts which were bound to be tentative. At first performed as a means of relief in a case of gastric cancer where excision was impossible, the earliest method was essentially crude and experimental. A loop of jejunum was brought up over the transverse colon and united to the anterior gastric wall. Crude as this expedient was, it gave great relief in that case and was repeated in many others, but it was speedily recognised as possessing many and serious drawbacks. Chief amongst these was "vicious circle vomiting." The loop of intestine fixed was long, and when distended with contents, heavy, and kinking of the gut almost always followed, if the patient lived long enough, at or near the site of union. Such kinking delayed the onward passage of material in the afferent limb, which consequently became distended and dilated. When peristalsis at last overcame the obstruction, so great a rush of fluid occurred that the stomach was flooded by jejunal contents, which it at once rejected through the mouth, and the last state of the patient was worse than the first. The loop of small gut also pressed upon the transverse colon and painful griping was added to the patient's sufferings. Von Hacker eliminated the long loop by his posterior method, in which the first part of the jejunum was united to the posterior gastric wall, but at that time and for long afterwards it was believed that one essential to success was that the peristaltic wave in both stomach and intestine should pass in the same direction. In order that this might be the case it was necessary that the jejunum should be turned upon itself, thus forming a loop in the afferent limb. A frequent result was that a kink was again formed with the consequent dilatation of the proximal gut and the reappearance of "vicious circle" vomiting. Various modifications were tried, the loop being attached more and more widely to the stomach, but all with much the same result. It was not until the Mayos of Rochester, U.S.A., demonstrated that isotonic peristalsis was not necessary that the present "no loop" posterior operation was perfected and "vicious circle" vomiting became a thing of the past.

The results of this, the "modern" operation, are all that could be desired. Pain and vomiting cease from the time of operation, the patient rapidly regains the power of taking the requisite amount of food and of digesting it, digestion now apparently taking place in the intestine, and consequently weight and strength are with fair rapidity restored. It is, however, of importance to note that in those in which the precedent pyloric obstruction has produced an appreciable loss of tone and motility in the gastric walls the full extent of the benefit to be derived from the operation may not be seen for some months. The case already mentioned of bilocular stomach is an instance of this, and I have seen many others in which the same fact has been noted, but in the majority the improvement is immediate and very striking. Here are two reports chosen from a great many:—"I have a constant feeling of thankfulness to be so healthy and strong. It is worth anything to be restored to good health. There has been nothing whatever to report in my condition that is unfavourable; I have not once been sick, however slightly, but am certainly stouter, and my appetite keeps always normal." This was the case of a man who almost died from hæmatemesis a few months before operation. "I must tell you that I am in the very best of health. I have not since the operation had *any* return of vomiting; the pains that I had previous to the operation have completely gone, and I am glad to say that all food agrees with me. I have been back at my work as a school teacher for three years without having a day's break through illness of any description. Previous to the operation I had been away from school six months, being unable to take any food. I am sure I cannot give you any better satisfaction than to tell you that I have since studied for and passed my final examination as a certificated teacher without any effect on my general health." But this patient had to wait three months before any marked improvement in her general condition was observable.

Behaviour of the New Stoma.

Finally, it has been a source of great interest to watch by means of the radiographic screen the behaviour of the new stoma as time goes on in those cases where it remains permanent. At first the food passes through at once. It is difficult to obtain such observations earlier than the eighth day, the patient not being in a fit condition to bear the exposure, but tracings show that at this time the food does not remain in the stomach any appreciable time but passes at once into the jejunum. Three months after,

whilst some passes at once, as soon as the intestine has received a certain quantity, presumably as much as it can at the time digest, the stoma closes temporarily and no more is allowed to enter; a clear space becomes visible between the food retained in the stomach and that in the jejunum. In a little while the stoma again opens and more escapes. This was at one time believed to indicate the formation of a new sphincter around the artificial opening, but is now believed to be due to reflex contraction of the muscular fibre of the gastric wall in response to stimuli received from the loaded jejunum.

There are, of course, many more points of interest in connexion with these operations and their results, but time will not permit of further enlargement upon them. Sufficient has perhaps been said to show the importance of the subject, the satisfactory results obtainable, and the necessity for ready—and early—diagnosis of the conditions remediable by them.

WILL NATIONAL HEALTH INSURANCE ENSURE NATIONAL HEALTH?

BY ERNEST J. SCHUSTER, LL.D.

(A) *Introduction.*

THE declared object of the National Insurance Bill is not merely the furnishing of help, making it possible for persons disabled by disease to take the necessary steps for the removal of such disease and to tide over the time during which their earnings are suspended, but also to bring about a general improvement in the hygienic conditions of the country. National health insurance is in this way intended, in a certain measure, to ensure national health. I propose in this paper to deal exclusively with this aspect of the Government scheme. The Bill proposes to improve the health of the country: (1) by measures regulating the general conditions of public health; and (2) by measures affecting the insured persons individually.

(B) *Proposals Intended to affect the General Hygienic Conditions of the Country.*

1. *Summary.*—Among the proposals intended to affect the general conditions the following require special mention: (*a*) the power conferred on the Insurance Commissioners to apply certain funds "for the purposes of research"; (*b*) the power conferred by Section 17 on any approved society or local health committee to grant subscriptions and donations for certain purposes concerning public health; (*c*) the rules contained in Section 44 (1) which make it the duty of each local health committee to inquire as to the special hygienic needs of the locality placed into its charge; (*d*) the rules contained in Section 46 as to the holding of inquiries in the event of there being excessive sickness in any locality; (*e*) the reference contained in Section 47 to the Exchequer grant for the construction of sanatoriums; (*f*) the inclusion among the "additional benefits" enumerated in the second part of the Fourth Schedule, under which additional benefits granted under the rules contained in the Bill may include "the building or leasing of premises suitable for convalescent homes and the maintenance of such homes." I have mentioned these various rules in the order in which they appear in the Bill, and will now try to analyse them in a more connected manner.

2. *Proposals as to sanatoriums fund.*—The million and a half of money which is to be applied in respect of sanatoriums has in reality no connexion whatever with the proposed scheme of insurance. The section dealing with it simply says that if Parliament grants a sum of money for the purpose in question the Local Government Board, with the sanction of the Treasury, may apply the fund so granted in any manner that may seem expedient; certain powers are conferred on such county councils as may receive any part of the fund; and the Local Government Board is authorised to form joint committees or joint boards for the purpose of facilitating coöperation between several county councils; but this is all the Bill contains on the subject.[1] The local health committees to be created under the Bill have nothing to do with the administration of this fund, and there is no provision in the Bill relating to the destination of the sanatoriums constructed at the expense of the fund, except that they are to be used for the treatment of tuberculosis or such other diseases as the Local Government Board, with the approval of the Treasury, may appoint.

The Bill does not give a right to any particular class of persons, whether insured under the Bill or not, to be received in any such sanatorium, nor is it clear from its terms whether the county council or other authority by whom a sanatorium is constructed will also be entrusted with the duty to manage and maintain it. It seems that all these matters are entirely left to the discretion of the Local Government Board, and under these circumstances it is quite impossible to say whether the large sum which is to be taken out of the public funds will be spent in a manner ensuring the kind of accommodation and management which can be of use in the fight against tuberculosis. There is no magic in the word "sanatorium." Not every building called by that name is a fit place for the reception of consumptives, and, moreover, the treatment of the patients is as important as the construction and the site of the building. It is important that on all these matters the authorities to whom the management of the funds is entrusted should have the most competent advice, and that they should not be tied down to any preconceived notion in favour of any particular method; but nothing has been done to ensure these objects.

The provisions of the Bill do not enable any authority to compel the patients to submit to sanatorium treatment. In Germany the experience on this subject has not been entirely satisfactory. In a circular letter issued by the Imperial Insurance Office on April 17th, 1909 (A.N. 1909, pp. 487, 488), it is stated that tuberculous patients are frequently disinclined to seek admittance in a sanatorium, and that the patients who seek admittance very frequently leave the institution after a very short sojourn, as they are frightened by the symptoms of their fellow-patients and by the cases of death occurring among them. If sanatorium treatment is confined to the treatment of the early stages of the disease, and to curable cases, such experiences may possibly be avoided; but these are matters requiring a great deal of care and discrimination, and it is by no means certain that the authorities entrusted with the management of the sanatorium funds are likely to exercise such care and discrimination to the desired extent. In Germany the institutions by which the insurance against invalidity is administered, though applying the sanatorium treatment as much as possible, have begun to think of other methods to be used in the struggle against consumption. They have begun to support the voluntary dispensaries which provide for the prevention of infection or which assist treatment in the early stages of the disease, and may supply the medical examination of the relatives of patients. Moreover, they use part of their funds in loans for the erection of healthy dwellings for workmen, and for other purposes preventing the spread of disease. The fact that there are 41 such institutions, each of which has a considerable amount of freedom in respect of the disposal and investment of its funds, is much more favourable to the adoption of discriminating methods than the excessive centralisation which characterises the British scheme.

3. *Proposal as to convalescent homes.*—The building or leasing of premises suitable for convalescent homes and the maintenance of such homes is mentioned as one of the additional benefits to which members of societies who have come under a scheme providing for additional benefits may become entitled pursuant to Section 8 (1) (*f*). A right to such additional benefits may arise in any case in which a friendly society applies its accumulated funds in a manner sanctioned by the Commissioners in accordance with Section 55, or in the case of any actuarial surplus being found to exist on the triennial valuation of the assets and liabilities of any approved society. As there are numerous other "additional benefits" which may be provided by any such scheme, and most of them are of more direct and immediate benefit to the individual members, it is highly improbable that the power to use funds for the object in question will ever be exercised; if it were to be exercised there would be a little more scope for originality and variety than in the case of the application of the sanatorium fund, were it not for the necessity of the Commissioners' approval, which in all probability would

[1] The proposal as to the grant for the erection of sanatoriums is quite unconnected with the provision of the "sanatorium benefit" referred to later.

be made dependent on the observation of a cut-and-dried set of rules. In this connexion it may be remarked that the Bill does not confer any right to convalescent treatment or any power to apply funds for such treatment (except that by way of additional benefit allowances of money may during convalescence be made to members). The German sickness insurance law enables any of the autonomous sick funds to pass rules entitling any insured person to be received in a convalescent home for any period not exceeding a year after the termination of his illness (Section 21 [3a] of the statute at present in force, Section 202 of the new law).

4. *Proposal as to support of hospitals and district nurses* — An approved society may, under the provisions of the Bill, become entitled to certain windfalls, which are to be applied in such manner "as may be prescribed." These windfalls include: (*a*) the contributions paid by employers for persons remaining uninsured on the ground of irregularity of employment or of their becoming employed after attaining the age of 65 (Section 4 [5]); (*b*) the contributions forfeited on the ground of non-payment of arrears (Section 10 [1]). Out of the funds so provided an approved society or local health committee may grant subscriptions or donations to hospitals or other charitable institutions, or for the support of district nurses, and also appoint nurses for the purpose of visiting and nursing insured persons (Section 17 as amended in Committee). Here, again, we have provisions which may be applied usefully, but the prospect of this being done is somewhat remote, as the accrual of funds in the manner described depends greatly on accidental circumstances, and as, moreover, it is very doubtful to what extent the approved societies and health committees will make use of the power thus given to them. It is a great pity that the Bill does not provide in a more definite manner for the support of hospitals and district nurses. The public will, rightly or wrongly, conclude that provision for sickness has to a large extent been taken over by the State, and it will probably take a long time before it will be realised how very imperfectly this has been done. In the meantime, a large part of the flow of charitable funds from private sources will be interrupted.

Another matter connected with hospitals and nursing also requires notice. The hospitals in Germany receive a great deal of support as a consequence of the rules which enable a sick fund to compel a member in certain specified events to substitute treatment in a hospital for medical benefit and sick pay (see Sickness Insurance Law at present in force, Sections 7. 20; New Law, Section 199), and which enabled the invalidity insurance institutions to apply hospital treatment in the case of patients likely to come under their charge (Present Invalidity Insurance Law, Section 18; New Law, sections 1253. 1254). The expenditure for these purposes during the year 1909 amounted as regards the sick funds to over £2,000,000 and as regards the invalidity insurance institutions to over £1 000,000. There is no provision in the British Insurance Bill other than the very limited authorisation contained in the amended Section 12 (2) (*c*) empowering an approved society to substitute hospital treatment for the other benefits, or enabling them to place patients under treatment for the sake of helping them to escape permanent invalidity. This removes a valuable method by which on one side the general health might be improved, whilst on the other hand a good source of income would be secured to the hospitals.

5. *Commissioners' research fund.*—Under Section 15 (2) each local health committee is to receive a Treasury grant amounting to 1*d.* in respect of each insured person residing in the area of such health committee for the purposes of being applied towards the administration of the sanatorium benefit, but the Commissioners are entitled to intercept such part of the aggregate sum payable in this manner to the health committees as they wish to retain "for purposes of research." Here, as in other cases a most undesirable uncertainty is created. The Commissioners will either have to curtail the amount applicable for sanatorium benefit, the sufficiency of which is in any case uncertain, or their power to use part of the Treasury grant for purposes of research will be entirely nugatory. Assuming that they exercise the power, the vagueness of the expression "purposes of research" will put them into a most unenviable position, as they will be inundated with proposals for the testing of innumerable inventions or theories.

6 *Health committees' powers of investigation and instruction.* —The local health committees, in addition to their duties as regards the administration of the sanatorium and medical benefits in respect of all insured persons and the administration of all benefits in respect of the deposit contributors, have a number of general duties, partly in competition with the existing local authorities. One of these duties consists in a general consideration of the needs of their respective areas with regard to "all questions of public health." As in the case of the above-mentioned "purposes of research," the indefinite nature of this expression allows our imagination to wander over a wide field, but before speculating on the questions, which may be suggested as fit subjects of investigation, we are bound to think of the more practical problem as to the method of raising the funds which would be necessary if any such inquiry is to be efficient; for without the assistance of experts an aimless wandering over the field of public hygiene will be useless, and it is hardly likely that experts will be found who will supply their knowledge without remuneration. The only funds available for the "general purposes" of the health committees are those derived from the sick pay of inmates of hospitals and sanatoriums who have no dependents and on behalf of whom no payment is made to the institution of which they are inmates (see Section 12 [2]), but these will probably not go very far. The medical officer of health for the particular area may, if he feels disposed and if he is requested to do so, attend the meeting of the committee and give his advice, but he will as a general rule not be able to spare much time for this purpose, and his unaided advice will in most cases be hardly sufficient. The health committee is also to make provision for the giving of lectures and the publication of information on questions relating to health; but here again we ask: How are the funds to be provided? And another question occurs: Will the health committees be so constituted as to make them proper agencies for the collection and distribution of scientific knowledge? Each of these committees is to consist—(*a*) of elected members being as to one-third representatives of the county council or borough council, as to another third representatives of the members of approved societies, and as to the last third of representatives of deposit contributors; and (*b*) of members appointed by the Commissioners, the number of which must, however, not exceed one fourth of the elected members. The elected members, many of whom will be necessarily persons of inferior education, will therefore form the majority. If the sole duties of these committees were connected with the administration of benefits their constitution could not be objected to, but as authorities on the subject of hygiene these bodies will not meet with sufficient confidence on the part of the general public.

7. *Inquiries in cases of excessive sickness.*—The power given by Section 46 to any approved society and to any health committee to bring about an inquiry in cases of excessive sickness due to the conditions or nature of employment, or to bad housing, or insanitary conditions, or to defective or contaminated water-supply, or to the disregard of any provisions contained in any Factory Act or Public Health Act is important, and may have satisfactory results, as there seems to be no doubt that at the present time the authorities who are entrusted with the superintendence of the matters in question are not sufficiently watchful. An inquiry instituted under the Bill may result in an order compelling the employer or the authority whose neglect has caused the excessive sickness to compensate the society or committee injured by such neglect for the additional outlay. It is obvious that the power to institute such inquiries will have to be exercised with caution, more particularly where a private employer is charged with neglect, but there is no reason to assume that the authorities with whom the decision will rest will be wanting in such caution. In any case the clause of the Bill dealing with this matter deals with a definite matter in a definite manner, while the other provisions connected with the regulation of public health to which I have referred have been shown to be of so uncertain a character that it is impossible to make any forecast as regards the effect which they are likely to have.

(C) *Provisions Relating to the Insured Individuals.*

1. *Administration of sickness benefit.*—If by any general scheme of compulsory insurance a state of things could be brought about under which efficient medical treatment could

be secured in all cases in which any person belonging to the poorer classes is in want of such treatment, one would be inclined to overlook many of the disadvantages attaching to the other parts of such a scheme, inasmuch as the benefit to the race which would follow would be so important as to make one inclined to pay almost any price for such a result. It is from this point of view that the question as to the position of the medical profession in its relation to the insurance becomes interesting to every member of the general community. The question whether or not the masses of the population are likely to receive efficient medical treatment under the State Insurance Scheme does not merely concern the medical profession, it concerns everyone who values the progress and well-being of his country. But efficient medical treatment cannot be secured unless a position be given to medical men making it reasonably certain that long years and large sums of money expended for the purpose of acquiring knowledge and experience and obtaining the use of a skilled eye and a skilled hand will not be spent in vain, that the "*res angusta domi*" will not unduly hamper the mental freedom, that the individual practitioner will not be so overtaxed by the number of cases coming under his care that he has to do scamped work and retains neither time nor mental energy for following the progress of medical science. Efficient medical treatment is not secured if the man who trims his sails to the wind, the man who wins his post by sacrificing his intellectual independence, the man who regulates his conduct by the requirements of those who have a voice in his selection—if, in short, the man of inferior moral character has a better chance of employment than one who follows his course without fear or favour. The German experiences have, I think, shown that any scheme under which the selection of medical men depends on popularly elected bodies is likely to favour the inferior man, but I must confess that the system of free choice of doctors (which has been adopted in the amended Section 14 (2)) seems to me as objectionable as the contract system. The system of free choice like the contract system gives the best chance to the worst man. The same type of man who, under the contract system, would have curried favour with the contracting committees will under the system of free choice curry favour with his patients, and as the whole claim to benefits under the insurance will depend on the medical certificate, it is not difficult to see how such favour will be obtained. If the medical benefit were to be restricted to persons whose total income does not exceed £100 the evils of either system would be reduced, because in that case there would be so much scope left for practice outside of the insurance scheme that employment under the scheme would cease to be an urgent necessity, but, even so, the position would in my opinion be unsatisfactory. If the insurance against temporary sickness is retained at all, the better way would be to dispense with the medical benefit altogether and to increase the sick pay, but so that the society or the committee administering the relief shall have power to refuse the sick pay if the patient is not under proper medical treatment, power being also given to require the patient to receive treatment and maintenance in a hospital in lieu of sick pay.

In connexion with the same question it must also be borne in mind that, as the Bill stands, large classes of the population are without the medical benefit, more particularly all children, all married women who are not in the regular service of an employer, all deposit contributors who have exhausted their deposit, all workers who work for their own account or for occasional employers, and are unable or unwilling to come under the unsatisfactory conditions of voluntary insurance, all insured persons who, through unemployment or other causes, have been unable to keep up their contributions during 26 weeks in each year of insurance, and all persons who have no regular employer, and cannot be admitted to an approved society. Some of these excluded classes live under the worst conditions, and the fact that their medical treatment is not secured would alone seriously interfere with the effect produced on the public health by the more efficient medical care to be received by the insured persons. I do not say that any scheme can be devised by which such efficient care could be secured for the whole population, but it is necessary to call attention to the marked insufficiency in this respect of the Government scheme, so as to show that voluntary effort will be required as much as ever. To help in the furtherance and organisation of such voluntary effort, under the guidance of those who are marked out as trustworthy leaders in the fight against disease, is the duty of every public-spirited man or woman.

2. *Sanatorium benefit.*—I have referred to the proposed grant for the erection of sanatoriums among the proposed measures regulating the general conditions of public health. As I am now dealing with the measures affecting the insured persons individually, I must say a word about the "sanatorium benefit" which is to be administered by the health committees. As I have already pointed out, the sufficiency of the fund allowed for this benefit is uncertain. When the sum coming out of the insurance funds (1*s.* 3*d.* for each person residing in the particular area) and the Government grant (one penny for each such person, less such amount as may be retained "for purposes of research") have been exhausted in any year, no farther sanatorium benefit can be provided. In so far as the fund is sufficient, the local health committee may make arrangements for placing an insured person in a sanatorium if they consider his case as suitable for sanatorium treatment (see Section 15). There is nothing to compel an insured person to accept sanatorium treatment if he is disinclined to submit to it, and inasmuch as an inmate of a sanatorium who has no dependents is (by virtue of Section 12 [1, 2]) deprived of sick pay, such a patient may well prefer sick pay to sanatorium treatment.

There remains the further question as to the nature of the sanatorium treatment to be applied. As I have said before, there is no magic in the word "sanatorium," and there are now many institutions called "sanatoriums" who do not supply the proper treatment required for the cure or alleviation of tuberculosis. As I need not explain to this audience, the patients suffering from tuberculosis belong to various classes, for each of which another kind of treatment is required. Is there any guarantee that the appropriate private treatment will be supplied? Is there a guarantee in cases in which, owing to the limited amount of the funds, a selection has to be made, that the most suitable cases will be selected? Having regard to the composition of the health committees to which I have already referred, the answer to these questions is very doubtful. Here, again, voluntary effort must step in to call attention to suitable cases, to supplement the funds in case they are deficient, to criticise the administration where it is faulty, to enlighten the population as to the precautions to be taken and as to the advantage of submitting to treatment when it is wanted and obtainable in a suitable form. Unless such voluntary effort assists the State scheme, the State scheme will be worse than useless. Such voluntary effort will also, as regards sanatorium benefit, be required for the assistance of the numerous classes excluded from the insurance to which I have alluded with reference to the medical benefit.

(D) *Concluding Observations.*

I think I have shown that both as regards the measures affecting the general health and those affecting the insured persons individually the provisions of the Bill are insufficient to secure the fulfilment of the far-reaching hopes which have been held out by its author and its more enthusiastic supporters, and above all that the voluntary agencies which have hitherto been active in the fight against disease will be as necessary as they were before. It would be a disastrous result of the legislation for compulsory insurance if the efforts of these voluntary agencies were to be relaxed, or if they did not continue to receive the unstinted support of the public.

"FIRST AID" ON THE ROAD.—Although scarcely three months have elapsed since "first aid" outfits were issued to the patrols of the Automobile Association and Motor Union and the men were required to qualify for "first aid" certificates, nearly 100 cases have already been reported by the patrols of services rendered to all classes of road users. Twelve cases of injuries by motor-cars were dealt with and over 40 cases of injuries to cyclists and motor cyclists. At Thornhaugh, on the Great North Road, recently a patrol went down a well to rescue a child who had fallen in. Although overcome by the foul gases he eventually recovered the child's body. The patrols have also relieved sufferers from wasp stings, machinery accidents, gun and gunpowder explosions, and a patrol who witnessed the fall of an aeroplane near the Coventry road was able to render prompt assistance to the injured aviator.

LYMPHATISM OCCURRING IN THE EAST.

BY A. WHITMORE, M.B., B.C. CANTAB.,
CAPTAIN, INDIAN MEDICAL SERVICE.

I SUPPOSE that it is now generally accepted that the persistence and growth of the thymus gland beyond the three-year limit, together with an undue development of the lymphatic tissue of other parts of the body, are signs that the owner thereof is so constituted that he or she is more than ordinarily liable to sudden death upon only very slight provocation. Hitherto it has been chiefly in connexion with deaths under anæsthetics that serious attention has been paid to the condition of the thymus and lymphoid tissue as of importance in deciding the cause of death, but if the danger of taking an exaggerated view of this undecided factor lymphatism is to be avoided, it is clearly of importance that some wider notice of its occurrence in deaths from other causes should be recorded. The fact that we did occasionally meet with the state among natives of Eastern countries was first brought to our notice by a case in August last year, and since then we have paid particular attention to the lymphatic development in the subjects who have been examined in the post-mortem rooms here.

Our observations extend from May 4th, 1910, to March 5th, 1911. During these ten months 585 bodies have passed through our hands; 20 of these have been so decomposed that a proper examination has been impossible, so that our observations must be taken as applying to 565 examinations.

CASE 1.—The first case which came to our notice and drew our attention to the condition as existing among the native community of the East was that of a Mahomedan girl, aged 3 years, whose body was brought by the police, having been recovered from a tank in the compound of a mosque. The history given by the relatives was to the effect that the child had been playing upon the edge of the tank and had been seen to fall in, the body being recovered about one hour later. There was no reason to doubt the correctness of this history. A post-mortem examination was held about five hours after the recovery of the body. The child was a well-developed rather stout little girl; decomposition was beginning; there was a little frothy mucus about the nostrils, but not more than is frequently seen in bodies which are commencing to decompose, nor was the mucus of that peculiar fine type so characteristic of death by drowning. None of the other external signs of drowning were present. In the internal organs no evidence of drowning could be found; the lungs were dry, and there was no water in either pleural cavities or stomach. The absence of all reliable evidence in the body of the known cause of death perplexed us not a little, and it was not until the examination of the intestine was taking place that any thought of lymphatism was entertained. Upon examining the small intestine the peculiarly prominent, raised, and corrugated appearance of Peyer's patches at once attracted attention, and upon re-examining the abdominal cavity the mesenteric glands were found to be all markedly enlarged, but discrete, and in no way suggestive of tubercular infection; it was then that the idea of lymphatism was first considered. As soon as looked for, there was no difficulty in finding the thymus; its weight when dissected out was 21 grammes. The inguinal, axillary, and cervical glands were moderately enlarged, and were discrete and of a pale pink colour; they were easily palpable through the skin. The tonsils were of fair size, but were not particularly enlarged, but the lymphoid tissue at the back of the tongue was very prominent. The organs of the body appeared to be in a healthy state, and there were no bruises about the head or other part of the body to suggest that in the act of falling the child had sustained injury such as to render her unconscious before immersion in the water.

This case has been dwelt on in detail because it was the first time that our attention was attracted to the condition of lymphatism as likely to be met with out here, and also in order that it may be understood that in this case, at any rate, too nice a care in observation was not responsible for the diagnosis. At this time our knowledge of such a condition was, practically speaking, restricted to the conception of its existence as an aid to anæsthetists in distress, for we had not then had the opportunity of reading the debate upon the subject which took place in May at the Royal Society of Medicine. After the experience of this case we have been taking particular note of the undue persistence of the thymus gland, and of any extraordinary development of the lymphatic tissue of the subjects of examinations, and have met with well-marked signs of lymphatism in 15 further cases. The cases are as follows:—

CASE 2.—A well-built, well-nourished Hindu male, aged 17 years. The supposed cause of death was drowning, but the history was unreliable. No obvious cause of death discovered; signs of drowning absent.

CASE 3.—A Zerbaddi woman, aged 25 years and well developed. The cause of death was hæmorrhage and shock from 18 large incised wounds, more than one of which would have been sufficient to cause death.

CASE 4.—A Chinese male, aged 19 years, a moderately well-developed youth. Death was supposed to have been caused by a fall from a tree from a height of about 20 feet, and the history was quite reliable, as there were several eye-witnesses of the accident. At the post-mortem examination no external injury was detected, and internally the only sign of injury was a shallow tear in the right lobe of the liver. There was no intra-abdominal hæmorrhage, and no obvious cause of death could be discovered; according to the bystanders this had been instantaneous.

CASE 5.—A well-nourished Zerbaddi male, aged 18 years; body picked up at the railway station. No history of illness or accident procurable. At the post-mortem examination the only sign of disease was a small patch of hæmorrhagic inflammatory consolidation at the upper part of the left lower lobe of the lung. In appearance this was suggestive of an infection with the bacillus pestis, but only pneumococci were discovered.

CASE 6.—A well-developed, well-nourished Chinese male, aged 50 years. The supposed cause of death was drowning, and the history was apparently reliable. Post-mortem examination did not disclose any of the usual signs of death by drowning.

CASE 7.—A well-developed muscular Burman male, aged 30 years. He had been found dead in his house; no history of any illness. At the post-mortem examination the organs of the body were found to be healthy; the stomach was full of a very large rice meal, and particles of rice were found in the larynx and trachea, so that the probable cause of death was returned as choking.

CASE 8.—A Burmese boy, aged 9 years. Cause of death, drowning; history quite reliable. At the post-mortem examination the only external sign of drowning was a little fine frothy mucus about the mouth and nostrils. Internally the only sign was some coarse froth in the large air-passages; the finer bronchi and the larynx and trachea were free from frothy mucus, and the lungs were dry and in no way suggestive of death from drowning.

CASE 9.—A Hindu woman, aged about 20 years, well developed and healthy-looking, who had been found in a tank, and as to whose death no history was to be obtained. Post-mortem findings: Decomposition not yet present to any marked extent; the only sign of drowning was a little fine frothy mucus about the nostrils and in the larynx and trachea; the lungs were free from fluid, and there was no water in the stomach. The organs of the body were healthy.

CASE 10.—A Burman male, aged 24 years. The supposed cause of death was suicide by poison. A tumbler containing a large quantity of crude cyanide of potassium was found by the side of the body, and from the viscera the chemical examiner recovered several grains of that poison.

CASE 11.—A native of India, a child aged 13 years, a well-grown boy. He had been playing outside a cocaine den and had picked up a small phial containing some of the drug, and it was supposed that he had taken a small quantity of the poison, as shortly afterwards he developed fits. He was brought at once to hospital but died upon admission. When first seen after admission his temperature was 103°F. and he died almost immediately afterwards. Post mortem no disease was found, but the chemical examiner found 1·1 grains of cocaine in the viscera.

CASE 12.—An Eurasian man, aged 22 years, brought to hospital dead from the effects of a stab wound of the chest. A very well-developed, athletic man. Post mortem the right coronary artery was found to be cut almost in two. The other organs of the body were healthy.

CASE 13.—A Hindu male, aged 25 years, admitted to hospital suffering from fever of two days' duration. He died shortly after admission. The body was well nourished. Post-mortem examination disclosed a patch of inflammatory consolidation in the lower lobe of the left lung: this was very hæmorrhagic in appearance, giving rise, as in the previous case, to a suspicion of plague, but only pneumococci were discovered upon microscopical examination. The other organs of the body were all healthy.

CASE 14.—A Hindu boy, aged 12 years, admitted to hospital for fits, the onset of which dated from the previous afternoon. He had never had fits before. Upon admission the neck muscles were a little stiff and there were some clonic spasms at short intervals (of which muscles the notes do not mention). There was no wound and no history of injury of any kind. A tentative diagnosis of tetanus was made. The boy died that night. The post-mortem examination failed to disclose any cause of death, although the kidneys showed some changes upon microscopical examination.

CASE 15.—A Hindu male, aged 16 years, brought to hospital with an extremely severe wound on the head caused by a fall while at work at the wharf. The frontal bone was badly crushed and brain-matter was escaping from the wound. He died soon after admission. Post mortem all the organs of the body were healthy.

CASE 16.—A Burman male, aged 24 years, brought to hospital dead, the supposed cause of death being cocaine poisoning, but the only evidence in favour of this hypothesis was the facts that he was known to be a cocaine eater and that he had died suddenly. The post-mortem examination showed severe aortitis, with marked narrowing of the orifices of the coronary arteries, such a condition as is not uncommonly the cause of sudden death.

In an analysis of these 16 cases it will, I think, be granted that in all of them—except, perhaps, Case 3—a condition which might without exaggeration be called lymphatism or status lymphaticus was present—that is to say, a state which has been accepted in many recorded cases as a cause of, or, at any rate, an important contributing factor in causing, sudden unexpected death, a factor which is still being energetically discussed in connexion with the occurrence of death under anæsthesia, yet in five, and probably in six, of the cases quoted above the deaths were due to causes other than any peculiar dyscrasia of which the persistence of the thymus gland and the general hyperplasia of lymph tissue are the outward and visible signs. For Case 3 died as the result of severe and necessarily fatal wounds, Case 10 from potassium cyanide poisoning, Case 11 from cocaine poisoning, Case 12 from a stab wound of the heart, Case 15 from a necessarily fatal head injury, while in Case 16 severe aortic

Evidence of Lymphatism Present in the Cases.

Nature and No. of case.	Thymus gland.	Lymphatic glands.			Lymphatic tissue of the tongue.	Spleen.	Intestinal lymphatic tissue.
		Axillary.	Groin.	Mesenteric.			
	Grammes.						
1, Drowning.	21	Enlarged.	Enlarged.	Markedly enlarged.	Prominent.	Normal.	Peyer's patches and the solitary follicles of the small intestine very hypertrophied.
2, Drowning.	30	Moderately enlarged.	Moderate.	Not obviously abnormal.	Very prominent, and tonsils enlarged.	Normal weight, 5½ oz.	Lymphoid tissue not conspicuously exaggerated.
3, Wounds.	5	Not enlarged.	,,	Not enlarged.	Prominent; tonsils enlarged but not greatly.	Normal.	Lymphoid follicles of the large intestine very conspicuous.
4, Fall.	23	Not obviously enlarged.	Enlarged and shotty.	Enlarged.	Tongue lymphoid tissue conspicuous; tonsils large.	Weight 6 oz.; lymph nodules conspicuous.	Solitary follicles of both large and small intestine hypertrophied.
5, Pneumonia.	25	Not palpable.	Palpable and shotty.	Slightly enlarged.	Not examined.	About four times normal in size, but not particularly lymphoid.	Moderate enlargement of the solitary follicles of the large intestine.
6, Drowning.	17	Palpable and shotty.	,,	No marked enlargement.	Well-marked prominence of the lymphoid tissue.	Slight enlargement (1½ times), otherwise normal.	Well-marked hypertrophy of the lymphoid tissue of the small intestine.
7, Choking.	*	Not enlarged.	,,	,,	,,	Normal.	Solitary follicles of both large and small intestine very prominent, also the stomach wall studded with small lymphoid follicles.
8, Drowning.	42·5	Palpable, discrete, and shotty.	Palpable, discrete, and shotty.	Well-marked enlargement.	Lymphoid nodules at the back of the tongue very prominent; tonsils large and elevated lymph nodules around the larynx.	Weight 3½ oz., lymph tissue marked.	Lymphoid follicles of the large intestine and lower half of the small intestine hypertrophied; also very numerous small lymph follicles throughout the duodenum.
9, ? Drowning	15	,,	,,	Moderately enlarged.	Nodules at the back of the tongue prominent.	Normal.	Lowest foot of the small intestine well-marked enlargement of the lymphatic follicles; also conspicuous, though small, lymph follicles in the stomach.
10, Poison.	23	Discrete and palpable.	Suppurating buboes.	Moderate enlargement.	Lymph nodules at the back of the tongue prominent.	Normal size, but lymphoid tissue increased.	Large and small intestine solitary follicles enlarged. Peyer's patches not hypertrophied.
11, Cocaine poisoning.	41·8	Very slight, not palpable.	Palpable and discrete.	Fairly marked enlargement.	Lymph follicles at the back of the tongue and post-pharyngeal lymph tissue hypertrophied.	Normal size, but lymphoid tissue excessive.	No enlargement of the lymph follicles.
12, Wound.	28	Moderate enlargement, discrete and palpable.	Moderate enlargement.	No marked enlargement.	Tongue not examined.	About 2½ times normal in size; lymphoid tissue not excessive.	No obvious hypertrophy of the lymph tissue.
13, Pneumonia.	21	Moderate enlargement.	Normal.	Normal.	Lymphatic tissue at the back of the tongue prominent.	Very large, about five times normal.	Lymphoid tissue normal.
14, ? Tetanus.	28	Moderately enlarged, but not palpable.	Well-marked enlargement; palpable and discrete.	Slightly enlarged.	Moderate hypertrophy of the follicles at the back of the tongue.	Normal.	Fairly well-marked hypertrophy of the lymphoid tissue, more especially of the solitary follicles.
15, Wounds.	12	Moderately enlarged; palpable.	Slight enlargement; palpable.	No very obvious hypertrophy.	Not noted.	,,	Peyer's patches of the lower portion of the small intestine hypertrophied to a moderate extent.
16, Aortic disease.	37·7	Slight hypertrophy, but not palpable through intact skin.	Well-marked hypertrophy; palpable and discrete.	Normal.	Nodules at the back of the tongue prominent, also post-pharyngeal lymph tissue hypertrophied; tonsils large.	,,	Solitary follicles of the large intestine hypertrophied; no striking enlargement of the lymphoid tissue of the rest of the intestinal tract.

* Weight not recorded; was of moderate size, probably 15–17 grammes.

disease was present, quite sufficient in itself to cause sudden death without an appeal to any peculiarity other than heart disease.

In Case 4 it would seem at first sight unreasonable to attribute the death to any constitutional peculiarity, but it is at any rate possible to suppose that his lymphatic state might carry with it an unusual liability to syncopal attacks and so contribute to the occurrence of the accident. We inquired from his relatives whether any proneness to giddiness or fainting had ever been noticed, but could discover no evidence of such having been present. However that may be, it is to be noticed that, so far as post-mortem signs of severe injury were concerned, they were limited to a slight tear in the liver, from which there had been no hæmorrhage, while the man is reported to have been dead when picked up immediately after the fall, so that he died apparently from syncope the result of the shock of the fall, a syncope which was probably aided by his constitutional condition. This would ally the case to Cases 1, 6, and 8; in these cases there was no doubt but that they had been immersed in water during life and that from a practical point of view they had met their deaths as the result of drowning, and yet the usual signs of drowning were either extremely scanty or absent altogether; syncope had apparently taken place almost immediately after immersion. Cases 2 and 9 were probably of a similar nature, although the absence of eye-witnesses of the probable accidents makes their deaths from drowning a surmise of which proof is impossible.

Cases 5 and 13 are of interest as cases of lymphatism which had contracted pneumococcal infection, and considering the facts that they were both well-grown, well-nourished young men, in whom the prognosis of lobar pneumonia ought to be exceptionally favourable, they both died in a most unusually early stage of the disease. In both these cases there were fairly numerous small hæmorrhages beneath the capsule of the thymus gland. In Case 14 it is quite impossible to say that the tentative diagnosis of tetanus was not the correct one, but if so it is certainly most unusual for that disease to follow such an extremely rapid course in the case of a healthy child without any external wound whatsoever. That some serious toxæmic state existed was shown by the condition of the boy's kidneys. Macroscopically the only abnormality to be detected was the presence of some scattered white streaks and spots, but microscopically the cells of the convoluted tubules stained extremely badly, in marked contrast to the rest of the kidney cells; while the white spots and streaks were found to consist of small round cells, such collections as would correspond with what have been described as "lymphorrhages." Whatever may have been the source of the toxin affecting the child, it seems reasonable to suggest that its effects were enhanced by the lymphatic dyscrasia present.

In three of the cases we carefully examined the state of the heart muscle, but in one only did we find any excess of fat, and in this heart the fat lay between the muscle fibres, not within them.

The younger brother of Case 8 was brought to hospital by his father for our examination, and was seen by my assistant, who found all the superficial lymph glands easily palpable, the tonsils were enlarged to a moderate degree, but without a laryngoscopic mirror he was unable to see the state of the lymphoid tissue at the back of the tongue, nor was he able with the means at his disposal to satisfy himself that there was persistence of the thymus.

Although I do not think that this series of 16 cases gives very much information as to the connexion between lymphatism and the liability to the occurrence of sudden death upon slight provocation, or as to the mechanism by which such death is brought about, yet it is, I hope, useful in showing that such a condition is not confined to Western peoples, but is probably as widespread out here in the East as in European countries; that it is not a condition in any way dependent upon race or environment, but exists among all races and in all climes. That this point has not hitherto been made plain is possibly due to the fact that here at any rate the operations for removal of tonsils and adenoids are, practically speaking, unknown, and it is, I believe, the tragic results in several of these minor operations which in European countries have attracted such wide and anxious interest to the occurrence of this condition and to its influence upon the individual's constitution.

Rangoon.

TWO RARE MANIFESTATIONS OF BILHARZIOSIS.

BY FRANK COLE MADDEN, M.D. MELB., F.R.C.S. ENG.,
PROFESSOR OF SURGERY, EGYPTIAN GOVERNMENT SCHOOL OF MEDICINE; SENIOR SURGEON, KASR-EL-AINY HOSPITAL, CAIRO.

CASE 1. *Bilharziosis of the spermatic cord simulating tuberculous epididymitis.*—A small Egyptian boy, aged 14 years, was admitted to Kasr-el-Ainy Hospital on May 30th, 1911, complaining of a hard swelling in the right side of his scrotum. He described it as starting, some months before admission, in a small lump above the right testicle, without any pain or other symptom, and gradually increasing in size and length. On examination it was seen that the right side of the scrotum was swollen, but there was no enlargement of the superficial veins or other abnormality externally. A hard, rounded, painless swelling was felt at the back of the testicle, but sharply separated off from it, and a chain of irregular nodules of varying sizes, extending along the cord half-way up to the external ring. The veins of the cord were free and the vas deferens could be felt above the mass quite thin and normal, but below it was entirely lost in the irregular mass. The testis was soft and smaller than its fellow. The skin was not anywhere adherent, and there was no softening of the nodular masses. No nodule could be felt in the prostate per rectum, though the gland was larger than normal. The urine contained no abnormal constituents and was said to be free of bilharzia ova.

Under anæsthesia the whole of the mass, including the testicle, was removed, the appearances both before and at the operation being considered to be tuberculous in nature. The small testis was found to be quite normal, but the whole of the epididymis was replaced by hard yellowish nodular tissue which extended up the cord for some distance. The vas deferens at the site of its section was thin and apparently normal inside and out, but just where it reached the mass were two yellow nodules, apparently typical tubercles. The greater part of the vas could be separated out from the mass, only becoming indissolubly incorporated with it in the lower part.

The peculiar appearances of the vas should have aroused our suspicions against tubercle, but we missed it, and were quite unprepared for Dr. A. R. Furguson's report, which was very short and to the point: "No signs of tuberculosis. The infiltration is bilharzial entirely, the nodular formations present being related to groups of ova as centres."

After recovering from the shock of this report a further investigation was made of the urine and *two* bilharzia ova were found after diligent search through four slides. For the rest, the urine was acid, of specific gravity 1016, and without deposit or other abnormality. Even had these ova been found before operation I do not think it would have altered our diagnosis, as such an occurrence is so common in Egypt at all ages that it might be easily passed without comment. In the face of the pathological examination, however, the discovery of ova became all-significant. The progress of the case was uneventful, and, admitting the mistake in diagnosis, I am convinced the treatment was correct as the testis must have been quite useless from a functional point of view, as there was such a complete replacement of the epididymis, tubes, and vas for the length of nearly two inches at the lower part of the specimen.

CASE 2. *Hæmospermia as the first symptom of bilharziosis.*—It has long been recognised that the vesiculæ seminales may become infiltrated with bilharzial tissue and at quite an early stage of the disease; but I had never, before the following case, met with one in which the presence of the disease in this situation furnished the first evidence of a general bilharzial infection.

The patient was an English soldier, who had been some years in Egypt, and consulted me on Nov. 7th, 1910, as he had recently experienced some blood-stained nocturnal emissions. He was not unnaturally alarmed and consulted a medical man in Khartoum, where he was then stationed, who told him not to worry "as there was no known disease that could produce such an extraordinary symptom and that it would pass off in time." The symptom continued, however, and was still present when I first saw him. I strongly suspected bilharzia as the cause, but before examining him in any way I sent his 24 hours' collection of urine to Dr. C. Todd for microscopical examination. The report came back that "the examination of the centrifugalised deposit revealed the presence of one single bilharzia ovum." The following day I confirmed the diagnosis by examination, and found that the vesiculæ seminales were thickened, especially on the left side, that the prostate was not enlarged, but the posterior wall of the bladder was thickened just above the prostate. Distinct, small, rounded elevations were felt with the sound, and a small papillomatous growth discovered just above the trigone and rather towards the left side.

On careful inquiry the patient admitted that he used to bathe in the Ismailieh canal, a stagnant stream at most times of the year and greatly favoured by natives as a public latrine, and that in October, 1909, he once passed a drop or two of blood after micturition. He also had some dull aching pain in the perineum from time to time. I put him on male fern and the usual *régime*, but there was really very little to treat. The urine was perfectly clear, and contained no albumin or other naked-eye abnormal constituent.

The case is interesting on account of the rarity of the special symptom above noted, and also because of its bearing on matrimony, which was contemplated in the very near future, and an opinion had to be given as to its advisability. After discussing the matter with my friend and colleague, Dr. Ferguson, professor of pathology, and going carefully into the cycle of the life-history from the ovum to the adult

worm, and the generally accepted theory of the mode of infection as propounded by Looss, we came to the conclusion that no risk of infection of the wife was likely to occur, and the marriage took place. The embryos can only hatch out in water and would soon die within their ova in the thick albuminous vaginal secretion.

Cairo.

A CASE OF ECLAMPSIA.

BY G. DE B. TURTLE, M.D. DURH., M.R.C.P. LOND.

THE patient, a married woman, aged 44, was first seen at 3 A.M. on July 9th, 1910 She gave the following history. She had been married five years and had one child, a boy, now nearly four years of age. Since his birth she had had two definite miscarriages and possibly more, the pregnancies being of about two to three months' duration. The previous confinement was normal, except for the facts that the patient's feet and hands had been somewhat œdematous for a few weeks beforehand, and that on the second day of her puerperium she is said to have had a slight fit, but no very definite account could be obtained. Her last period commenced on Oct. 19th, 1909, and lasted five days, so that presumably she would be confined about July 26th. For the last few weeks the patient had had some swelling of her legs, arms, hands, and face, accompanied by severe headaches and dimness of vision. For the last few hours she had experienced great pain in the lumbar region and a blood-stained discharge per vaginam.

On examination the patient was found to be œdematous practically all over, the legs and feet being greatly swollen; by abdominal palpation the child was found to be lying with the head downwards and with the back lying to the left and in front (left occipito-anterior); the fœtal heart sounds were readily heard at a rate of 140 per minute. The vaginal examination was difficult owing to the œdema of the walls; the os uteri was patulous and admitted the tip of the index finger, but it was not possible to reach the presenting part. There were no true labour pains, and the loss by the vagina was only slight. A specimen of the urine was examined. It had a specific gravity of 1015, and on being boiled it became nearly solid with albumin. Some blood was also present, but this was probably of vaginal origin. A portion of the specimen of the urine was centrifugalised and the deposit examined microscopically; it contained renal cells, epithelial casts (both fatty and granular), blood corpuscles, and vaginal and bladder epithelial cells.

During the next 24 hours the patient passed only 13 oz. of urine. An enema had previously been administered with but little result, so active purgation with jalap and scammony was resorted to. The bowels consequently were freely opened. The œdema became less and the patient felt better. The blood pressure was taken with a Martin's modification of Riva-Rocci's sphygmomanometer. It registered 190 mm. Hg. The fœtal heart sounds were 124 per minute. During the next 24 hours 54 oz. of urine were passed, and there was much less albumin present in the specimen. The arterial blood pressure fell to 170 mm. Hg, and the fœtal heart sounds were 132 per minute. During the next 24 hours 75 oz. of urine were passed and the blood pressure was 165 mm. Hg. The amount of albumin decreased to 6 grm. to the litre as estimated by Esbach's albuminometer.

On the morning of July 12th a consultation was held as to the advisability of inducing labour, but as the symptoms were improving so rapidly and the œdema was fast disappearing, and as the fœtal heart sounds were quite regular and easily heard, it was decided to await events. At 4 P.M. on the same day, possibly owing to the excessive purgation, labour commenced naturally; the vertex presented with the occiput pointing to the left and anteriorly. A vaginal examination was made about 8 P.M., and the cervix was found to be dilating well and the labour pains were quite regular. At 9.45 the patient suddenly said that she felt something was coming away from her. On examination a hand was seen to be presenting at the vulva with a loop of the umbilical cord. It was impossible to perform version or replace the hand. Chloroform was administered and forceps immediately applied to the head, which was lying in the vagina. Delivery was easily effected as the head was somewhat small; the child, a male, was born asphyxiated, but the heart was beating very feebly and quite slowly. Direct insufflation was commenced, and after being persisted in for 45 minutes voluntary respirations commenced and continued until 2 A.M., when the child had convulsions. Small inhalations of chloroform were administered, but the fits continued, although at longer intervals. Between the intervals of the fits the child had some nourishment administered, and after the first 12 hours a little improvement was shown. Besides this method of treatment small quantities of potassium bromide in solution were given by the mouth, subcutaneous injections of saline solution (a teaspoonful of sodium chloride to a pint of sterilised water) and oxygen inhalations were all tried, but the child eventually died at 12 noon on July 14th—i.e., 38 hours after birth. No post-mortem examination was made, so that the question as to the origin of the fits, whether they were due to meningeal hæmorrhage or whether they were of toxic origin, must remain in doubt; sufficient to say, however, that they closely resembled eclamptic convulsions in character, commencing with marked lividity and tonic spasm and ending with stertorous breathing.

On the afternoon of July 13th the patient complained of headache and dimness of vision, and at 9 P.M she had an eclamptic convulsion followed by another at 10.30 P.M. A hypodermic injection of morphinæ sulphas, gr. ½, was given, followed by a hot pack, which produced very profuse sweating. The bowels were opened by calomel and magnesium sulphate. As far as could be ascertained about 50 oz. of urine were passed on this day. On the 14th, 120 oz. of urine were passed by the patient in about 12 hours, and on the 15th 84 oz. The blood pressure was still 170 mm. Hg, but the amount of albumin in the urine was considerably less, measuring 4 grm. to the litre. On the 16th there was a small scotoma in the centre of each field of vision (toxic amblyopia). The bowels were being moved, and there was a fairly large quantity of urine passed. The breasts had become swollen and painful, and were full of milk; at her previous confinement they had never shown any signs of activity, but their activity this time was probably due in some measure to the large amount of fluid, especially barley-water, which the patient had been taking by the mouth.

On July 18th, by abdominal palpation the involution of the uterus was found to be progressing normally, and the breasts were less active. An ophthalmoscopic examination was made, but there were no hæmorrhages to be seen in the retina, nor was there any papillitis or cloudiness of the optic disc. The skin during this period was acting very freely, and was doubtless assisting greatly in the elimination of the poison. Good progress was made until July 23rd, when the patient's left leg swelled and became painful; the swelling subsided, however, by the next day. On the 25th the patient still complained of pain in the leg and also "neuralgic pain" in the hip. On the 27th there was pain in the shoulder, and the temperature rose and the pulse became more rapid. These symptoms increased until the 29th, when the temperature was 100·2°, the pulse 130, and the respirations 40 per minute, with rather shallow breathing. No physical signs could be found in the lungs; the albumin in the urine was also increased, being about 2 grm. to the litre. The symptoms then subsided until August 4th, when the patient again had pain in the right side of the chest accompanied by a rise of temperature, increased pulse-rate, and rapid breathing—not so marked an attack, however, as the former. During both of these attacks the patient had been troubled with a short, irritating cough, with little or no expectoration and no hæmoptysis. On August 10th, as there were no cough and no pain and the pulse was 88 and quite regular, the patient was rolled from the bed on to the sofa and remained there some hours, the same proceeding being adopted on the 11th. On the 12th I was called at 5 A M, as the patient was said to be having another attack. According to the nurse's account the patient woke at 5 A.M., having slept very well for some hours. She was extremely dyspnœic, the respirations being very shallow and rapid; great pain was complained of at the back of the neck and in the centre of the chest. The pulse was 90 per minute and regular, but it soon became more rapid, and at 5.30 A M. was 120; the patient was cold and felt faint and exhausted. When I saw her about this time there was extreme dyspnœa and a constant cough. The pulse was 130 per minute and rather feeble, the skin was cold and clammy, and the face livid; in fact, she looked to be *in extremis*. Ether, m. 20

subcutaneously, was given, and ½ oz. of brandy in 2 oz. of warm milk was administered by the mouth. The patient's colour improved, but the pulse remained feeble, so that at 8.15 A.M. digitalin, gr. 1/100, was administered hypodermically. Throughout the day the patient had frequent inhalations of oxygen, and at 8 P.M. the pulse had dropped to 116 and she felt better. This fortunately proved to be the last of her attacks, for from this time onwards her recovery was uninterrupted.

On August 31st the urine was examined; it had a specific gravity of 1016, was slightly cloudy, and contained a trace of albumin (by Esbach ½ grm. to the litre), but no sugar. A portion which was centrifugalised showed bladder and renal epithelial cells and bacillus coli in fair numbers but no casts. In February, 1911, six months later, the urine contained no albumin and the blood pressure was 135 mm. Hg.

This case is of interest in several ways:—1. The rapid improvement in the patient's condition under treatment before labour came on. 2. The fall in blood pressure and the accompanying rise in the output of urine. 3. The nature of the three attacks of dyspnœa which the patient had during the puerperium. 4. The nature of the convulsions which the child had and from which it succumbed.

With regard to the third point, I am of the opinion that the patient had a clot somewhere, possibly commencing in the left femoral vein, as evidenced by the swelling of that leg on July 22nd, and that small emboli were cast off and carried up to the right side of the heart and so into the lung. Why to the right lung only it is difficult to say. There were never any physical signs in the lungs and there was no hæmoptysis. The alternative idea was that these attacks were due to cardiac dilatation, but it will be noted that they commenced with dyspnœa and cough and the pulse became rapid afterwards.

With regard to point 4, I have already mentioned that the possibility of cerebral hæmorrhage could not be excluded, but the way in which the fits came on with tonic spasm, finishing with clonus and stertorous breathing, certainly pointed to their being of toxæmic origin.

In conclusion, I should like to thank my friend Dr. Ernest Playfair, not only for much help at the time of the labour, but also for seeing the case with me from time to time afterwards, and for many valuable suggestions in the treatment.

Cambridge-terrace, Hyde Park, W.

THE INFLUENCE OF SALICYLATES AND KINDRED DRUGS ON THYROID ACTIVITY.

BY H. EWAN WALLER, M.R.C.S. ENG., L.R.C.P. LOND.

THIS subject involves of necessity some consideration of thyroid activity in relation to fever. It is a tempting theory that the ordinary symptoms of fever are due, at least in part, to increased thyroid activity, such activity being one of Nature's methods of dealing with toxins which may have obtained access to, or been formed within, the body. Evidence in favour of this supposition has been supplied by Roger and Garnier, who found that in acute infectious diseases with fever there is increased thyroid activity with enlargement of the folliculi, which are filled with a large quantity of colloid substance. Further, we have ample evidence that thyroid exhaustion is commonly manifested by clinical symptoms as a sequela of febrile diseases. Dr. Arnold Lorand has discussed the whole matter in a most interesting article which appeared in THE LANCET of Nov. 9th, 1907, and throughout that article he certainly cannot be accused of underrating thyroid influence. He attributes the rapid pulse, abundant perspiration, polyuria, and diarrhœa all directly to thyroid influence, and quotes experiments to show that the rise of temperature may very well be due to the same cause. The supposition is attended with certain difficulties, and if we accept it we shall be driven to certain other logical conclusions. Throughout we shall take Graves's disease as our standard of excessive thyroid activity.

Now, the process of fever is not a solitary and simple condition, but a complex cycle of events, which tends, however, to follow a fairly definite course. Accepting thyroid activity as the main factor, we shall attempt to interpret events as we go along. Firstly, there is a sensation of lassitude and chilliness, which is probably a signal that toxins have gained access to the system, which has used up all the available thyroid secretion in attempting to neutralise them. And though the thyroid sets to work with all diligence to make more, for a time the secretion is neutralised by the toxins as fast as it can be produced. Thus there is a period of temporary thyroid deficiency in spite of rapid production. The deficiency accounts for the sensation of cold, often amounting to actual shivering, and also for the constipation which is so frequently present. It may also account for the febrile want of appetite, often observable also in patients who suffer from thyroid inadequacy, and possibly even for excessive thirst, which I have likewise often noticed in similar cases, though so far as I am aware the symptom has not been noted elsewhere. One point about the thirst is that cold water is the drink preferred to any other, a fact which may be readily verified by inquiries among half a dozen children suffering from minor degrees of thyroid inadequacy. On the other hand, we must assume that the thyroid activity is in itself the cause of the increased pulse-rate and rise of temperature. The flushed face, the sensation of throbbing carotids and temples, and the consciousness of every heart beat are all familiar features both in Graves's disease and fever. The tremor and sensation of fatigue will be equally witnessed in both conditions. But as yet we have no sweating, which is almost invariable in Graves's disease. In fever this occurs later, and with it the fall of temperature. On the other hand, pyrexia is by no means a constant feature of Graves's disease.

Here are two difficulties which require careful handling, and have possibly proved a stumbling-block to some who might otherwise have accepted this theory before. The difficulty can be got over by the following explanation. A rise of temperature is the immediate effect of big doses of thyroid, whether administered by the mouth or by sudden hyperactivity of the patient's own gland. Pyrexia is also prone to occur when the surgeon unintentionally floods the system with thyroid secretion by manipulation of the gland during operation. But sweating only occurs when the organism finds itself flushed with more thyroid secretion than is required. Thus in Graves's disease, where secretion is in excess all the time, sweating is the rule. Again, during active exercise there is evidence of increased thyroid activity shown by increased pulse-rate and flushed skin, but sweating does not occur till secretion is in excess of demands, the first supplies being presumably taken up by fatigue products. And in fevers, when the production of thyroid secretion exceeds the amount required to neutralise the toxins, sweating occurs, followed by a fall of temperature. The improved condition of the patient is fully in accordance with this view. The fall of temperature is partly regulated by evaporation of sweat, but probably depends still more on reflex inhibition of the thyroid gland, which has now succeeded in the task it set out to perform—namely, neutralising the toxins, producing secretion enough and to spare. The duration and severity of the symptoms will naturally depend on the amount of toxins produced, and the capacity of the thyroid to neutralise them in a longer or shorter time. The dose may, of course, be more than the thyroid can deal with, or hyperpyrexia may result from excessive thyroid activity. Such contingencies do not affect the argument as a whole, and it may be fairly claimed that the position is at least not untenable.

Similarly, it has been argued that salicylates (and presumably other antipyretics) produce their effects by thyroid stimulation. A moderate dose of salicylate of soda in the healthy subject produces (according to Mitchell Bruce) "increased cardiac action, flushing and warmth of the surface with perspiration," and other symptoms which are to some extent peculiar to the drug. So far, this may very well be explained on Dr. Lorand's assumption that salicylate of soda acts by stimulating thyroid activity. And in fevers, when thyroid activity is already high, a dose of salicylate of soda may still further stimulate the gland and so hasten the sweating and general abatement of the symptoms. Whether the proceeding is beneficial or not is quite another matter, and involves the whole question of uses and abuses of antipyretics. The patient feels better with a fall of temperature and a good sweat, but sometimes the temperature rises, again bringing

back all the previous discomfort, and in this case we may well wonder whether we have been premature in our efforts or not. In theory, of course, when the illness is commencing and toxæmia still slight, if by a few doses of salicylates or other antipyretics we can hurl into the circulation enough thyroid secretion to form antitoxins or annihilate the germs by whatever mode is usual, we may then congratulate ourselves on having cut short the attack. Howbeit, our method may have been extravagant, and if we have miscalculated the hidden forces arrayed against us we may have committed a grave strategical error which perhaps would not have been done by Nature unaided.

It is, of course, possible or even probable that salicylates have an action which is hostile to micro-organisms or even poisons of other origin, and that benefit accrues from such action quite apart from thyroid influence. But the point I wish to lay stress on is that salicylates have a powerful influence against thyroid activity. In view of what has just been said this seems a startling statement and therefore requires proof. Whether salicylates powerfully stimulate and so rapidly exhaust thyroid activity, or whether they actually neutralise it, and so in the case of an active gland stimulate further production (like lemon-juice and saliva or alkalies and gastric secretion), I cannot say, but the evidence I am about to bring forward points to the latter conclusion. I will quote three cases.

CASE 1.—A robust adult had an acute tonsillitis. He had stuck to his work for three or four days when I first saw him one morning. He had then taken to his bed with a pulse-rate of 120 and temperature 102° F. He had headache, and aches and pains in the limbs severe enough to suggest rheumatism, but possibly only influenzal. He was given a mixture containing 15-grain doses of sodium salicylate and half-drachm doses of compound tincture of cinchona. But owing to variations in the size of the domestic tablespoon he took repeatedly a larger dose, roughly 20 grains of salicylate and 40 minims of bark every four hours. The error was not discovered for 36 hours. He then had a (morning) pulse-rate of 48 and temperature of 96·4°. He had sweated profusely the first night, and his bowels were obstinately constipated, resisting strong doses of aperient. The pulse and temperature remained at this low level all the next day, and the bowels were still obstinately constipated in spite of aperients, though the salicylate mixture had been left off. Thyroid, 2½ grains twice a day, was then given for two days and the temperature again rose, this time to nearly 101°, and the pulse to 98. The throat progressed rather slowly in spite of energetic antiseptic treatment which had given me excellent results in other cases. The patient returned to work 12 days after I first saw him, when in spite of full doses of strychnine he had a very soft dicrotic pulse of 76 and a blood pressure of only 100 mm. Hg.

I have already mentioned that this patient was usually robust, and may add that ordinarily his bowels were remarkably regular. The low pulse-rate, the dropped temperature, and obstinate constipation all suggest that in this case the thyroid was seriously depressed by the drugs mentioned. The low blood pressure was probably due to the same cause, inasmuch as high blood pressure is a common feature of Graves's disease. There is a widely prevalent idea that thyroid activity lowers blood pressure. It causes flushing of the skin and sweating, so the conclusion is a natural one. Actually, I am certain that it is wrong. Cretins and thyroid deficients have low blood pressure, and repeated observations have shown me that thyroid administration almost invariably raises blood pressure, possibly by simple acceleration and augmentation of the heart beat. Hence the ill effect of large doses of thyroid on a heart with feeble muscle. If this interpretation be correct, it is probable that the heavy doses administered did harm and prolonged convalescence.

CASE 2.—The patient was a woman, aged 39, who had suffered from life-long constipation and manifested the ordinary signs of minor thyroid inadequacy. Her general condition had been enormously improved and constipation much lessened by thyroid medication. On one occasion her bowels had been perfectly regular for over a week without any medicine other than thyroid, and she could not remember that this had ever occurred before. At the time of which I now write she was taking a small dose of cascara nightly, and was somewhat tired owing to disturbed nights entailed by her duties as nurse. She was given aceto-salicylic acid for a slight attack of lumbago, from which she had been suffering for several days, and though the dose did not at any time exceed 10 grains thrice daily, her constipation greatly increased, and the nightly dose of aperient medicine had to be more than doubled while taking this drug. It is only reasonable to suppose that the increased constipation was due to exaggeration of the thyroid depression caused by the aceto-salicylic acid.

CASE 3.—This was a case of Graves's disease. I had previously found aspirin to be of great value in controlling paroxysms of tachycardia, and accordingly prescribed a daily morning dose of 10 grains for this patient, who usually had an attack of palpitation after breakfast. The remedy was perfectly successful, and in view of the cases just quoted I resolved to try the effect of three or four doses daily. The result was rather remarkable and more than justified my expectations. The pulse-rate improved considerably and the patient felt very much better. Her bowels, which had previously been open twice and often three times a day, were now open but once daily. She increased 2 lb. 1 oz. in three days. Though this increase in weight might be attributed to fæcal accumulation it does not affect the argument, inasmuch as the previous intestinal activity was due to excessive thyroid action. The only objectionable feature was some gastric disturbance, which may have been caused by using a less pure substitute for aspirin. Sweating was, if anything, less than previously.

More prolonged experience of this treatment is necessary before one can pronounce final judgment, but I think it proves that aspirin and possibly other salicylates and allied drugs will be found of inestimable value in Graves's disease. One might avoid the gastric disturbance and possibly get still better results by local use of one of the easily absorbed salicylic compounds directly applied to the skin over the thyroid gland. The final result naturally depends on whether thyroid control or exhaustion will cure Graves's disease or otherwise, which is quite another question and cannot now be discussed.

Further, in view of the beneficial results recently obtained by thyroidectomy in inoperable cancer, similar benefit might be obtained by the use of aspirin in such cases, many of which are also unsuitable for thyroidectomy. Aspirin has, of course, been used for the relief of pain in cancer, and this may explain the *modus operandi*.

Birmingham.

MEDIASTINAL CAUSES OF CHRONIC COUGH IN CHILDREN.

BY HERBERT FRENCH, M.A., M.D.OXON., F.R.C.P.LOND.,
ASSISTANT PHYSICIAN, MORBID ANATOMIST, AND LECTURER AT GUY'S HOSPITAL, ETC.

IT happens again and again, especially in towns, that young children suffer from a persistent cough which lasts on and off for weeks or months without being materially relieved by any of the ordinary cough mixtures, lozenges, linctuses, or syrups, and yet without any very obviously abnormal physical signs being discoverable to account for this cough. Not a few such cases are attributed in an indefinite kind of way to adenoids or to tonsils and adenoids, or to mouth-breathing; but there is another cause at work in at any rate one group of these cases—namely, chronic enlargement, sometimes no doubt associated with tuberculous caseation, of the glands at the bifurcation of the trachea. When a large number of post-mortem examinations are made the fact obtrudes itself that the bronchial gland immediately below the right bronchus is affected far more frequently than is the gland upon the left side, and the right phrenic nerve is frequently seen to be displaced by the enlarged lymphatic gland in such a way as probably to be much irritated by it and thus to lead to attacks of purposeless coughing—that is to say, coughing which does not succeed in the bringing up of any sputum. In a certain number of cases it is possible to demonstrate the enlargement of this right bronchial gland by means of the X rays, as the following case demonstrates.

The patient was a healthy-looking, chubby-cheeked girl, 7 years of age, who was brought to the hospital with a history that she had suffered from a bad cough for months without this cough apparently being benefited, except perhaps momentarily, by the administration of any of the usual

remedies. There were no abnormal physical signs to be made out in the chest, but the possibility of there being a caseous bronchial gland was suggested first by the fact that the girl had been in the habit of drinking large quantities of unboiled London milk—a very prolific source of this type of tuberculous infection, I believe—whilst an elder brother had died from tuberculous meningitis, which is also related much more closely to cow's milk infection than to a phthisical family history. On examination of the chest with the X rays the heart and the diaphragm appeared to be normal, the latter moving fairly well on both sides. The lungs themselves were quite clear at their apices, but bulging to the right of the spine in the region of the root of the right lung there was a very obviously abnormal shadow corresponding precisely with an opaque and presumably caseous gland close to the root of the right lung.

It is probable that the attacks of coughing which are so troublesome in some heart cases are to be explained by irritation of the phrenic nerves in a similar way, by their being displaced and stretched by the dilated and hypertrophied heart.

The importance of realising that enlarged bronchial glands may be the cause of persistent coughing in children is that the enlargement is generally tuberculous, and therefore the correct treatment is to adopt the general hygiene best adapted to the relief of a tuberculous infection together with measures calculated to prevent the swallowing of more living tubercle bacilli, an end to be accomplished either by obtaining milk from cows that have been satisfactorily tested with tuberculin, or else by making sure that any tubercle bacilli in the milk have been killed by efficient sterilisation, preferably by thorough boiling.

Wimpole-street, W.

"COMFORTER" OTITIS MEDIA.[1]

BY W. H. BOWEN, M.B., M.S. LOND., F.R.C.S. ENG.,

LATE SURGEON TO THE ROYAL EAR HOSPITAL, LONDON; HONORARY CLINICAL ASSISTANT, EAR, NOSE, AND THROAT DEPARTMENT, ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

MIDDLE-EAR suppuration may occur at all ages from earliest babyhood to extreme old age, but the seed of disease is usually laid down before puberty, and the object of this paper is to express an opinion as to the origin of suppurative otitis media in babies.

If we consider the possible ways of infection of the middle ear we find that these are three. This infection must take place either (1) by way of the external auditory meatus; (2) by the blood stream; or (3) by the Eustachian tube.

1. Now the first of these may be at once eliminated, for infection from this source usually means mischievous endeavours to remove wax or foreign bodies from the meatus, with damage to the membrana tympani, and there would be a clear history.

2. Infection by the blood stream means an associated septicæmia. I believe that such when it occurs usually has the pneumococcus as the infecting organism,[2] and ofttimes there is a history of pneumonia. When such cases occur the patient is usually ill with, or convalescent from, pneumonia, and the middle-ear disease may be associated with other complications, such as empyema, abscess of the skin, arthritis, and even peritonitis. Referring to this type of case, my memory is carried back to the case of a small child who was under the care of one of my medical colleagues at the East London Hospital for Children. This child, after an attack of pneumonia, developed acute otitis media and arthritis of the right shoulder-joint. I opened the shoulder-joint and washed it out, and treated the ear discharge with lotions, and both complications cleared up without further difficulty. At the time of operation films of the pus were made from the joint and the middle ear, and in both a Gram-positive diplococcus, morphologically identical with the pneumococcus, was found.

3. But the point about these babies with middle-ear suppuration, which are brought to an out-patient practice, is that they often appear as fine, healthy-looking infants. Usually if anything is wrong with them it is that they are anæmic. They are free from fever, from signs of other illness, or history of other illness, and, in fact, it is impossible to associate them with a septicæmia, of which the middle-ear disease is a local manifestation. When first I took out-patient work at the East London Hospital for Children the origin of this suppuration perplexed me. As there was no evidence of infection by the meatus, nor yet by the blood, the only conclusion to arrive at was that the infection was by the Eustachian tube, and naturally on the top of this conclusion came the question: How does this infection take place?

Adenoids sufficiently large to be obstructive are uncommon in infants under 18 months, and certainly under 12 months they are rare. They do occur, I believe, but even in the large out-patient practice of a children's hospital such cases are rare, and the class of case to which I am now particularly referring are obviously nose-breathers, have no heaviness of breathing, no chronic nasal discharge, or other sign pointing to adenoids. Between two and three years of age, cases of adenoid enlargement, complicated with middle-ear disease either as chronic suppuration, recurrent suppuration, or pain in the ear or ears, are common; but they are so well recognised by the profession that I need not emphasise that it is not the class to which reference is made here.

The concentration on the subject resulting from seeing a large number of babies suffering from chronic suppuration of the middle ear drew my attention to the constant association of the comforter or dummy and this middle-ear disease; and once this association has been remarked, the correlation can be worked out quite easily, arguing by analogy. In the present day it may be stated as a recognised fact that in older children adenoid growths and middle-ear disease are intimately associated as cause and effect; and we recognise that the association, speaking without any special exactitude, is that the adenoids lead to embarrassment of nasal respiration and some resulting opening of the mouth; that through the opened mouth cold, dry, and unpurified air enters, gradually lowers resistance, and leads to the infection of the oro-pharynx and naso-pharynx, including the adenoid region; and that the adenoid region can at once become a vantage-ground for organisms because of its crypts, its shut-in position, great vascularity, and free secretion. The openings of the Eustachian tubes situated on the side walls of the naso-pharynx are constantly exposed to infection, and we are only too well aware in how large a number of cases the organisms get to the middle ear.

Now it seems to me that the great danger of adenoids is the mouth-breathing, leading to oral and naso-pharyngeal sepsis. This is borne out by the observation that middle-ear disease will ofttimes not clear up, despite the removal of adenoid growths and suitable local treatment, unless nose breathing is established. It seems fair to argue by analogy that a large number of cases of middle-ear suppuration in babies result from oral sepsis introduced, not by mouth-breathing, but by the comforter or dummy. I would here remind my readers that this theorising on the subject came after the observation made in an extensive out-patient practice of a Children's Hospital, and it was this observation which led me in the first place to associate the so-called comforter with this suppuration.

The way in which the comforter acts is by introducing oral sepsis. Usually the comforter is a rubber teat in some sort of bone collar, and fixed on to the baby either by a piece of ribbon, tape, or string, and when not in the baby's mouth touching all sorts of unclean things; and from the fact that the surface is usually moist and sticky from saliva and mucus, particles of all sorts adhere. Then it is a lamentable practice on the part of baby-tenders to give the comforter a preliminary suck before putting it into the baby's mouth, and to anyone who has had any experience of the neglect of the teeth which occurs among the servant class in this country the variety of organisms thereby introduced into the comparatively clean mouth of an infant can be more easily imagined than described.

This, in my opinion, is the crux of the matter. The comforter is at fault only in so far as it introduces sepsis leading to what are probably catarrhal processes, giving very little, if any, signs or symptoms in the mouth, oro-pharynx, and naso-pharynx; but once they spread by the tube to the middle ear the lack of drainage quickly becomes felt and suppuration often results. That catarrh alone may result, with painful distension of the middle ear, is probable from the occurrence

[1] A paper read at a meeting of the Cambridge Medical Society.
[2] Pneumococcal Otitis Media, by the writer (see West London Medico-Chirurgical Journal, April, 1908).

of pain in the ears in some babies who never get discharge coming from the meatus. Even if it gets no further than a painful catarrhal process, however, it is capable of doing considerable damage in a small enclosed space like the middle ear.

It is not my intention to deal with the pathological changes arising from middle-ear suppuration, but reference may be made to the permanent damage which results from destruction of the ciliated epithelium of the Eustachian tube and which may leave an unguarded path for future infection. All otologists will have met with cases of suppuration occurring later in life where the patients have stated that as babies they were said to have had discharging ears; and again, it is of no uncommon occurrence in examining a patient for some catarrhal deafness associated with later years to find healed and even unhealed perforations of the membrana tympani, where the patient never remembers having had suppuration of the middle ear, and where the inference is that it occurred at a very early age.

I have no intention to dogmatise. It is now my firm belief that a large proportion of cases of suppuration of the middle ear in infants is directly due to the comforter, and I am in the habit of labelling them "comforter" otitis media; but I am also very well aware that there are lots of babies who suck comforters but never suffer from ear trouble, and, on the other hand, that there are cases where middle-ear disease occurs although a comforter has never been used. Given a comforter which is cleaned regularly, never allowed to touch anything dirty, and never placed in any mouth but that of the infant, the septic element is eliminated and all may be well. Experience suggests that it is a high standard to maintain, but there is no reason why it should not be maintained if the comforter is held to be necessary. As regards the cases where suppuration occurs without any comforter to point to as the *fons et origo mali*, they will probably be found to be few in number, and the cause may possibly lie in mouth sepsis from other causes, just as occasionally one finds middle-ear suppuration in older children without a trace of adenoid enlargement.

The prognosis of these cases may be said to be good, both from the point of view of cure of the suppuration and maintenance of hearing power. In treatment the aim will be to remove the cause, cleanse the mouth, wash away the discharge from the middle ear and so prevent accumulation and stagnation of pus, and, finally, to provide against any secondary infection by way of the meatus from outside. These guiding principles are carried out in practice by eliminating the comforter or rigidly enforcing its cleanly use, cleaning the mouth with some mild antiseptic preparation such as glycerinum boracis and so preventing further infection by the tube, and treating the existing suppuration by syringing out the middle ear three times a day with some weak antiseptic lotion after instilling a few drops of hydrogen peroxide (10 volumes). Finally, it is a routine of my practice to advise the wearing of some antiseptic wool in the concha, to prevent secondary infection from the outside in between the syringings. This last precaution is especially necessary in babies, because of the risks of getting soapy water into the ears when they are bathed.

Cambridge.

THE TREATMENT OF TORTICOLLIS:

A PLEA FOR A REVISION OF ACCEPTED TREATMENT.

BY PAUL B. ROTH, F.R.C.S. ENG.

SURGEON TO THE KENSINGTON AND FULHAM GENERAL HOSPITAL; ORTHOPÆDIC CLINICAL ASSISTANT, LONDON HOSPITAL.

THE observations in the following paper apply to the torticollis which is met with in children, which is usually described as congenital, and which is due to a non-spasmodic shortening of one sterno-mastoid muscle. The aim of the paper is to call attention to the fact that after torticollis has been treated by tenotomy no retentive apparatus is necessary. The four cases described were in-patients at the London Hospital, under the care of Sir Frederic Eve, to whom I am indebted for permission to publish their notes.

It is generally taught in orthopædic works that the treatment for this condition is division of the muscle, followed by use of retentive apparatus. Thus Tubby says: "The principles which should guide us in undertaking operative measures are:— ..... 2. After tenotomy, to maintain the improved position by means of a simple apparatus, and such as does not interfere with daily manipulations."[1] "The head is fixed in plaster in the over-corrected position for 10 to 14 days, and the patient is then sent out with a plaster-of-Paris collar. It is well to divide this anteriorly, and to lace it, so that it may be taken off, and daily movements of active and passive manipulation practised. The collar should be worn for four to six months."[2]

Bradford and Lovett, 1900, say: "The head should be immediately rectified and retained in a corrected position, either by means of a plaster-of-Paris bandage enclosing the head and trunk, or ..... the bed frame described in the treatment of caries of the spine. ..... This can be employed for a week or ten days, and a light retention appliance be used."[3] "This latter should be worn for from three to six months, when permanent cure should be established. Without the use of apparatus after operation relapse is likely to occur."[4]

Royal Whitman, 1907, says: "The head should be fixed during the process of repair in the over-corrected position. ..... In this attitude a plaster bandage should be applied surrounding the head and the thorax. It should remain ..... until the tendency towards deformity has been checked."[5] "Fixation in the over-corrected position is very important in childhood as an aid in overcoming the deformity habit. ..... The plaster bandage is usually retained from four to eight weeks. When it is removed, massage, manipulation, and gymnastic training are indicated."[6]

Stewart, 1908, says: "In the operative treatment two points of importance call for consideration: first, to rectify the distortion by cutting or by manipulation; second, to maintain the head in a suitable position by some form of apparatus."[7] "The very best form of the latter is the plaster helmet. ..... After the wound has healed the helmet may be left on for from four to eight weeks, or even longer."[8] "If, after the splint has been removed, it be found that the deformity be overcome, it will be necessary, in order to prevent its return, to institute systematic exercises, to employ massage, and constantly to take advantage of posture."[9]

Finally, G. A. Wright, 1910, gives an account of the use of elastic traction after tenotomy for torticollis,[10] and obviously regards its use as necessary.

The above quotations would show that after operation the use of retentive apparatus is imperative. I wish to point out that it is superfluous.

It will be noticed that both Whitman and Stewart advocate systematic exercises *after* retentive apparatus has been worn for many months; and that Tubby recommends them *concurrently* with it. I submit that they should be used *from the first*, and without apparatus of any sort whatsoever. It will be seen further that these writers do not state what exercises should be done; there is only a general statement about them. Unfortunately, in the majority of orthopædic works, whenever exercises are mentioned, the same absence of detail is noticeable.

While house-surgeon at the London Hospital in 1909 I operated upon four cases of torticollis. After division of the muscle and fasciæ by the open operation the head was firmly manipulated into an over-corrected position. The child was then put back to bed with the head between sandbags, and on the second or third day was allowed up and gentle passive movements were begun. On the fifth or sixth day active movements took their place, and after removal of the stitches the mother was shown how to superintend the carrying out of these movements at home for five minutes twice a day. These four patients are completely cured. By "cured" is meant that a year after operation the child holds his head perfectly straight, that he can twist his head round to look over one shoulder just as well as over the other, and that only by finding the operation scar can the affected side be discovered.

4 Ibid., p. 590.
5 Royal Whitman: Orthopædic Surgery, 1907, p. 655.
6 Ibid., p. 656.
7 Stewart: American Practice of Surgery, 1908, vol. iv., p. 774.
8 Ibid., p. 779.
9 Ibid., p. 780.
10 Wright: Brit. Med. Jour., "Elastic Traction and Pressure in Surgery," Nov. 26th, 1910, p. 1667.

The exercises are as follows, carried out with the patient lying supine on the table:—

1. *Head twisting.*—The head is slowly rotated as far as it will go to the right, then slowly to the front again, then slowly to the left, then slowly to the front, the patient counting audibly 1, 2, 3 during each movement. This is repeated six times.

2. *Head sideways bending.*—The head is laterally flexed slowly to the right, so as to bring the right ear close to the right shoulder, then slowly back to the median position, then slowly to the left, then slowly back again. During this exercise the patient looks up at the ceiling, and the back of the head rests on the table, in contrast to exercise No. 1, when he looks alternately over one shoulder and then over the other. As in the former exercise, the patient counts aloud during each movement, which is repeated six times.

At first these movements are performed passively by the surgeon; but the patient is encouraged to help actively, and by the fourth or fifth day can do them perfectly well by himself. When the child leaves the hospital after the stitches are out, the mother is shown what the exercises are, and is made to carry them out in the presence of the surgeon. It is explained to her why the exercises are ordered, and why she must continually correct the patient if he holds his head crookedly. The patient is not seen again.

It has been objected that the mothers of hospital patients are not sufficiently intelligent to carry out home treatment of their children. It will be found that the stupidity of the mother bears an inverse ratio to the care and patience of the surgeon. The four cases were as follows:

CASE 1.—A. B., reg. no. 3371, aged 5 years. Difficult labour, instrumental; head presentation. Left torticollis, only noticed one year ago. Operation Sept. 11th, 1909. Left hospital Sept. 17th. Not heard of until April 13th, 1911, when the mother said he held his head perfectly straight, and was just the same in every way as his brother (see Case 3). The exercises were done for three months.

CASE 2.—C. D., reg. no. 3664, aged 4 years. Normal labour. Left torticollis, first noticed when 11 months old. Operation Oct. 7th, 1909. Left hospital Oct. 13th, but came back to have stitches removed. Not seen until April 21st, 1911, when absolutely cured. The exercises were done for one year.

CASE 3.—E. F. (brother of patient in Case 1), reg. no. 3812, aged 11 years. Breech presentation. Left torticollis, noticed when 7 or 8 years old. Face asymmetrical; left eye lower than right. Operation Oct. 19th, 1909. Left hospital Oct. 24th, but came back to have stitches removed. Not seen until April 13th, 1911, when absolutely cured. Face symmetrical. Exercises done for three months.

CASE 4.—G. H., reg. no. 3885, aged 4 years. Difficult labour, instrumental. Right torticollis, noticed when 6 months old, when received by foster mother. Operation Oct. 22nd, 1909. Left hospital Nov. 11th. Not seen until April 13th, 1911, when absolutely cured. Exercises only done one week.

Thus complete cure has been brought about in four cases without the aid of retentive apparatus; that is to say, in these four cases retentive apparatus was needless. Is it not needless in all other cases which come within this scope?

There is nothing new in what I have written: my father in 1884 [1] drew attention to the same matter. Yet still the use of retentive apparatus goes on, and each surgeon endeavours to invent some new apparatus when none is wanted.

Harley-street, W.

A CASE OF SUPPURATING INGUINAL OVARIAN HERNIA; OPERATION; RECOVERY.

BY JOHN J. WADDELOW, F.R.C.S. ENG.

THE patient was aged 28, and had been married 11 years; she had had three children. The first confinement took place on July 22nd, 1901, when an impacted occipito-posterior presentation was delivered by perforation and cephalotripsy after ineffectual endeavours by forceps. Her second confinement was on Feb. 12th, 1906, when she was successfully delivered of a living male child by forceps. Her third confinement took place on Oct. 13th, 1910, when a dead child was delivered with great difficulty by high forceps (Neville's axis-traction). About six months after her second confinement she noticed a lump in her right groin, which she thought she had brought on by lifting weights (she had been changing houses). At first the lump would be only down occasionally and always going back at night when she reclined. Sometimes it would come down when she put her feet to the ground. During pregnancy the lump was never in evidence.

There was never any actual pain, only a dull ache, [illegible]ng a feeling of sickness and making walking difficult. Thinking that this was an ordinary rupture, without taking any professional advice, she, after her own fashion, measured herself for a truss, which she sent for to a neighbouring town by the carrier. As might be supposed, this truss did not fulfil the purpose for which it was intended. After her third confinement on Oct. 13th all went well till Oct. 24th when the temperature rose to 103° F. Nothing was found to account for it, and in about a week it gradually subsided without giving rise to any symptoms. After a few days she got up and came downstairs. On the first day after getting up the lump reappeared. On Nov. 15th, after a hearty supper, she went to bed, and about 4 A.M. I was suddenly summoned on account of her waking up in violent pain. On my arrival I found that the pain was in the right iliac fossa; the temperature was 103·4°. I ordered hot fomentations and a liquid diet, fully expecting I had a case of acute appendicitis to deal with; but instead of the usual constipation the bowels became loose, and on Nov. 18th the pain and tenderness were much less and the temperature had fallen to 100°. Then it was that she told the nurse about the lump, who immediately told me.

On examination there was a tender swelling in the right inguinal region a little below the external ring just at the top of the right labium majus. The swelling was irreducible and no impulse could be obtained, but after manipulation it ached considerably. With the decrease in the pain and tenderness in the right iliac fossa the reverse occurred in the groin. The swelling became red and very tender. This was the condition of affairs on Nov. 21st and the temperature had risen from 99° to 100·4°. The bowels were slightly constipated, but there was no vomiting or collapse indicating strangulation. I advised operation.

On the following morning (Nov. 22nd), although she was menstruating profusely, I cut down, making the usual incision for radical cure of inguinal hernia. The skin had become thickened and œdematous, and after proceeding very carefully I came upon a round mass surrounded by a large quantity of organised lymph. In working round this with my fingers the abscess gave way and discharged a quantity of odourless pus. After some patient manipulating I succeeded in separating the mass from its surrounding adhesions and tracing it up to the external abdominal ring, when I put some traction on; the mass proved to be the ovary and the Fallopian tube with the broad ligament. This I drew down and ligatured with silk, and having cut off the ovary I let the stump slip back. I failed to find any trace of a peritoneal sac. I then proceeded to pass a suture through the external pillar of the ring when a sharp gush of venous hæmorrhage occurred. What was actually pricked I could not tell, but my index finger was in the canal and the point of the needle was pressed against it. This gush stopped on pressure, and I refrained from any further attempts at ring suture. The wound was washed out and united with ten interrupted silkworm-gut sutures, and a small drain was inserted at the lowest point.

No pain was experienced after the operation, but on account of the menstruation the dressing had to be changed the next day and again on the following day. On Nov. 24th the temperature was normal and the tube was taken out and a collodion dressing substituted for the bandage. On Nov. 29th three stitches were removed and on Dec. 2nd the rest were removed, the wound having healed by first intention despite the presence of pus at the operation. On Dec. 7th the patient got up for the first time.

Doubtless during pregnancy the fundus of the uterus rising up drew upon the Fallopian tube and brought the ovary away from the neighbourhood of the internal abdominal ring to a higher position in the pelvis, and then on the occurrence of involution it returned to its old position. The interesting points, clinically, were that the condition simulated appendicitis, making it doubtful whether the acute attack of pain was in reality appendicitis. Again, that as the abdominal symptoms waned the inguinal ones waxed.

Hernia of the ovary is usually an infantile condition and associated with a patent canal of Nuck as in a congenital hernia. Hernia of the ovary coming on in adult life by itself and not as a portion of a pre-existing hernia is a rare

[1] Bernard Roth: Brit. Med. Jour., "The Treatment of Non-Spasmodic Wry Neck," June 14th, 1884.

occurrence; as is also the absence of any sac. The case also goes to show how reticent some women are in confiding all their troubles to the medical attendant; and also how some will attempt to diagnose and take the treatment of their condition into their own hands.

Whittlesey.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF RECURRENT ILEO-CÆCAL INTUSSUSCEPTION; OPERATION; RECOVERY.

BY J. D. FIDDES, M.A., B.SC., M.B., CH.B. ABERD.,
LATE RESIDENT MEDICAL OFFICER, ROYAL HOSPITAL FOR SICK CHILDREN, ABERDEEN.

THE patient, a boy, aged 3 years, was admitted to the Royal Hospital for Sick Children, Aberdeen, at 11 A.M. on Feb. 24th, 1911. He had become acutely ill on the same morning at 5 o'clock. The condition on admission was as follows. Temperature 98° F.; pulse 120. The child looked very ill, and every few minutes brought up a green bilious vomit. There were very evident spasms of severe colicky pains coming on every three minutes, during which he cried and drew up his legs. The bowels had moved the day before admission, when the stool was green and foul-smelling. The child was now passing only clear mucus by the rectum. No blood had been seen. The abdomen was soft and easily palpable. The patient was very quiet between the spasms of colic. A distinct sausage-shaped tumour was discovered at the outer edge of the right rectus just below the liver. No abnormality was felt per rectum.

The mother stated that for the last 18 months the child had been troubled with constipation, and had several acute attacks of colicky pains, but that medical advice had not been sought, except on two of these occasions when the pain had been more severe. Dr. Laura S. Sandeman had been called in, who kindly informed me that the first of these occasions was about ten months previous to the present attack when the case was diagnosed as one of intussusception, a distinct tumour being felt on the right side of the abdomen. There was at that time vomiting, but no blood was passed by the rectum. The medical attendant arranged immediately for the child to go into hospital, but on returning to see him previous to removal found that all the symptoms had disappeared. The attack lasted 24 hours. The second severe attack was about three months before admission, and was somewhat similar to the first. On this occasion the child again had vomiting of a bilious character, but, in addition, had passed blood per rectum. The attack lasted only from three to four hours. There had been two or three minor attacks between these two severe ones.

On admission the child was at once taken into the operating theatre and Mr. H. M. W. Gray opened the abdominal cavity by a paracentral incision, retracting the right rectus muscle outwards. There was found to be a well-marked ileo-cæcal intussusception, about 2 inches in length. The ileum about 8 inches from the ileo-cæcal junction was seen to be bound down by adhesions to the upper and back part of the pelvis for the extent of about 2½ inches. The appendix was partially embedded in these adhesions and was 6 inches long, club-shaped, and showed distinct signs of chronic inflammation. The intussusception was reduced easily. The adhesions joining the ileum to the pelvis were then divided and the raw area left was covered by transplanted omentum which was fixed in position by a few interrupted iodine catgut sutures. The appendix was removed and the abdomen closed. Ether, given by the open method, was administered by Dr. A. Ogston.

The recovery of the patient was uneventful. There was no post-operative vomiting and no special post-operative treatment was adopted. The bowels moved naturally 24 hours after operation, and in 56 hours the child was on ordinary hospital diet and looking exceedingly well. The skin sutures were removed on the fourth day and the boy left hospital on the tenth day after operation.

The interest of the above case lies in the fact of the lack of any very severe symptoms, the comparatively small extent of the intussusception, and of the spontaneous cure of the previous attacks, all of which were, without doubt, due to the presence of the adhesions between the lower part of the ileum and the pelvis, which prevented more than the "slack" of the ileum from entering the intussusception. The child has remained in perfectly normal health since the operation.

I am indebted to Mr. Gray, surgeon to the hospital, for permission to publish this case.

Sheffield.

NOTE ON A TOXIC EFFECT OF ASPIRIN.

BY ALEXANDER BROWN, M.B. LOND., M.R.C.S. ENG., L.R.C.P. LOND.

ASPIRIN is frequently taken by persons without medical advice, and a toxic symptom which I believe must be fairly common, though little commented upon, is therefore worth noting.

Several years ago I was called at night to see a man to whom I had that day prescribed tabloids (10 grain doses) of aspirin for rheumatic fibrositis of the shoulder muscles. I found him pacing his bedroom in a state of great alarm and presenting an extraordinary appearance. His face was bloated so as to be hardly recognisable, the lips were immensely swollen, the palpebral fissures were closed owing to œdema of the lids, the tongue was so enlarged that it could not be protruded, and he was unable to articulate. Large dusky wheals of urticaria covered the thorax and arms. The condition had developed suddenly. After some hours, during which I remained with him, giving him ice to suck and sips of cold strong infusion of tea, the condition subsided sufficiently to enable me to see his fauces, which were œdematous and dusky. All medication was stopped, and by next day the patient had recovered. I suspected the aspirin, but he himself ascribed the condition to food poisoning. At a later date, in order to test the accuracy of my opinion, I prescribed one tablet (5 gr.) of aspirin. This was followed by urticaria of the arms which lasted for a day.

A second experience of the kind has occurred in my practice. A young woman gave the following history. She had returned from business on a Saturday afternoon with a headache and had lain down for a few hours, and had then risen and dressed to go to an entertainment, but at the railway station she suddenly felt her lips, jaws, and tongue to enlarge, and she returned home in great alarm. Her mother stated that her face was almost unrecognisable, being covered with a swollen rash. When I saw her, an hour and a half later, there was nothing whatever to see except one or two faint blotches on the arms. I put the question, "Have you been taking any tablets?" "Yes," was the answer; "but only two aspirins for my head." The diagnosis was clear.

It is interesting to think whether such toxic effect is due to impurities in the drug, or whether it may be idiosyncrasy. Probably it is the latter, for though in the first case mentioned above the drug was probably pure, in the latter case there was not the same guarantee with the tablet. Nevertheless, the young woman remembered on three previous occasions to have taken aspirin without such result. And even if the toxic effect be due to impurity it is quite likely that idiosyncrasy must still be called in to explain the occasional poisoning which occurs among the hundreds of people who take the undoubtedly large number of impure specimens of the drug on the market.

Bartholomew-road, N.W.

NOTE ON A CASE OF TORSION OF THE TESTICLE.

BY WILFRID ATTLEE, M.D. CANTAB., M.R.C.S. ENG., L.R.C.P. LOND.,
ASSISTANT PHYSICIAN, KING EDWARD VII. HOSPITAL, WINDSOR.

THE following incident may prove of interest to the readers of THE LANCET.

A boy at school, aged 16½ years, was kicking a football about, and felt some pain in the right testicle. He took little notice of it, and came in when he had finished his game, had his bath, and ate his tea. The pain continued, however, and increased, and he began to feel faint and

vomited twice. I examined him about three hours after the first symptoms; he was lying on a couch looking white and faint, and evidently in considerable pain. The right side of the scrotum looked larger than the left, and the right testicle was drawn up towards the external ring. Palpation caused pain, but it was easy to make out that the external ring contained no hernia, that the right cord felt thick and hard, and that the right epididymis was in front of the testis, and lying towards the middle line. It seemed evident that the testis was twisted upon its cord, and probable, from the history, that the twist was in the direction of the hands of a clock, if one looked upwards towards the patient's head. Manipulation proved that this deduction was correct, for after turning the testis back through about a right angle the epididymis rotated with a jerk back to its normal position, and the pain immediately disappeared. Ten minutes later the boy had regained his colour and felt perfectly well. He has had no symptoms since.

The boy tells me that he had a blow on the right testicle some year or two ago, and he thinks this testicle has been a little smaller than the other since then. The right testis is certainly a little smaller than the left at the present time, but except for this there is nothing abnormal about it. It would be interesting to know why a testicle should stick in such a position, and whether such a condition would have righted itself if left alone, or gone on to strangulation and possibly to gangrene. At any rate, the apparent rarity of the occurrence seems sufficient justification for recording it.

Eton.

Reviews and Notices of Books.

A Treatise on Diagnostic Methods of Examination. By Professor Dr. HERMANN SAHLI, Director of the Medical Clinic, University of Bern. Edited, with additions, by NATHANIEL BOWDITCH POTTER, M.D., Assistant Professor of Clinical Medicine at Columbia University (College of Physicians and Surgeons), New York. Second edition, revised. Authorised translation from the fifth revised and enlarged German edition. London and Philadelphia: W. B. Saunders Company. 1911. Pp. 1229. Price 27*s.* 6*d.* net.

Professor Sahli's book on diagnostic methods is so well known and has attained such an established position as a standard work of reference that any detailed review of its contents, even if such were possible within small limits, is unnecessary. We may therefore confine ourselves to a brief notice of its scope and general character, with mention of some of the new matter included in this, the second English, edition.

The term "diagnostic" methods is taken to comprise any procedure which is calculated to afford information in regard to the diagnosis of a patient's condition. Consequently it includes physical methods, as well as the laboratory and instrumental investigations which are now so various and of such wide application. The descriptions given are always practical and sufficiently detailed to enable the process under consideration to be carried out. Although many alternative methods may be described, Professor Sahli invariably states which, in his opinion, is the most reliable. His book is no mere collection of methods copied from other works or from special monographs, but a carefully digested presentation of his own experience. It is this personal note which gives the special character to the book, and renders it one to which reference may be made for practical assistance in working out the nature of difficult cases. It also contains a number of original observations upon many matters which have not been published elsewhere.

In connexion with the nature of fever Professor Sahli rejects the commonly accepted view that it is due to a disturbance of heat regulation, and suggests that it is essentially a circulatory disturbance by which blood is diverted from the skin to the deeper organs, with the results that heat dissipation is lessened and the febrile rise of temperature brought about. He believes in the existence of "latent fever"—i.e., a febrile disturbance of the circulation without rise of temperature. He also maintains that fever is purposeful, and that the altered circulatory conditions act beneficially by bringing more blood to the damaged viscera. The raised temperature is, in his view, a by-effect, and not necessarily beneficial. Some interesting observations upon dyspnœa are directed to showing that this is strikingly adapted to the particular respiratory obstruction causing it. Some tracings by Hofbauer showing graphically various types of respiration are included.

The newer methods of investigation of the circulatory system are examined at some length, and copious illustrations of the instruments used and of the tracings obtained by them are given. Professor Sahli, however, urges caution in the interpretation of small waves upon the venous tracing, especially in conditions of irregularity. It is remarkable that no mention of electro-cardiographic methods is made in this connexion. In referring with approval to Bäumler's work upon arterio-sclerosis, it is maintained that this condition is often diagnosed upon insufficient grounds and that arterio-sclerotic changes are frequently very unevenly distributed, so that thickening of a superficial artery is not sufficient evidence of general arterio-sclerosis. The chapter on percussion contains a full discussion of the explanation of the percussion note and of its modifications.

The methods of examination of the stomach and intestines are described at great length. In particular the analysis of the gastric contents and the use of various test meals, with the information obtainable from them, are exhaustively dealt with. Professor Sahli's own methods, including the desmoid and glutoid tests, and the butyrometric process for examination of the gastric functions, are fully discussed and defended against the criticisms to which they have been subjected. The sections dealing with the examination of the urine, sputum, and blood are brought fully up to date. Professor Sahli brings forward a suggestion that pernicious anæmia is a consequence of diminished hydrochloric acid in the gastric juice, with a resulting diminution in the absorption of iron. He reviews the main facts of the disease in the light of this theory. He minimises the importance of hæmolytic processes in this disease, but his arguments do not seem to us to carry conviction. The question of exploratory punctures is fully discussed, and the new work upon the cytology and chemistry of the fluids obtained is included. The examination of the nervous system is discussed systematically and is as exhaustive as the other sections of the book. The subject of aphasia is considered in detail, and the recent views of P. Marie are criticised adversely.

The book is copiously illustrated by diagrams, plates, and photographic reproductions. The translation has been well done, and the editor has contributed numerous notes. Many of the illustrations of cases have apparently been added by him, as they are derived from American sources. We can recommend this book as a valuable work of reference.

Lehrbuch der Magen- und Darmkrankheiten mit besonderer Berücksichtigung der Diätetischen und Medikamentösen Therapie. (*Text-book of Diseases of the Stomach and Intestines, with Special Consideration of Dietetic and Medicinal Treatment*) Für praktische Aerzte und Studierende. Bearbeitet von Dr. P. RODARI, Privatdozent an der Universität, Zürich. Zweite völlig umgearbeitete und bedeutend erweiterte Auflage. (Second fully revised and enlarged edition.) Wiesbaden: J. F. Bergmann. 1910. Pp. 521. Price 12 marks, or 12*s.*

THE clinical investigation of diseases of the digestive organs has been enriched by numerous methods of examination which have rendered diagnosis and treatment of these conditions much more rational and exact than was formerly

possible. Dr. Rodari in his introductory chapter complains that these methods are not yet sufficiently applied, either by practitioners or by many hospital teachers. He states that superficial diagnosis depending upon some prominent symptom or sign, such as dyspepsia, constipation, diarrhœa, and dilated stomach, are still much too common, and that practitioners, who would not be satisfied by a superficial diagnosis of heart disease in a case of valvular lesion, are content with equally vague statements in diseases of the digestive organs. Dr. Rodari's book is well adapted to supplying the information necessary to remedy these deficiencies, for it affords an exhaustive consideration of the etiology, pathology, symptoms, signs, and methods of investigation of these diseases, and in addition gives full details both in regard to diet and medicinal treatment.

The section devoted to diseases of the stomach is divided into two parts. The first treats of the general diagnosis of gastric conditions and includes an exhaustive review of questions of diet, drugs, balneotherapy, and physical methods in the treatment of gastric disorders. In the second part, the individual diseases are separately considered. Dr. Rodari gives valuable directions for obtaining a satisfactory history from patients, each symptom being clearly discussed in regard to its value and significance. The various methods of examination and the chemical and other measures devised to investigate the physiological efficiency of the stomach are described in detail. The individual diseases of the stomach and disorders of the gastric functions are exhaustively considered. We may mention the description of gastric ulcer as being an admirable presentation of the subject. The treatment is described in full detail, and the merits of the various diets recommended, notably those of Leube and Lenhartz, are critically discussed. Dr. Rodari is in every case careful to give reasons for his statements, in the form of references to authorities or to experiments made by himself with special reference to the matter under discussion. The subject of nervous gastric affections, or neuroses of the stomach, is also dealt with in an interesting and lucid manner.

The second part of the book deals with diseases of the intestines. This also is divided into two sections. The first is devoted to general considerations, while the second deals categorically with the individual affections of the intestines. In the general part the symptomatology of intestinal diseases is critically reviewed, and the various diets, drugs, and other therapeutic measures are discussed. The purgatives, astringents, and antiseptics are especially considered. The classification of the intestinal affections given by Dr. Rodari is simple and convenient. He describes the various inflammatory conditions of the mucous membrane, including acute and chronic enteritis, membranous colitis, and appendicitis. The next group comprises the ulcerative conditions of the bowel, including duodenal ulcer. New growths are then dealt with. Anomalies of the intestinal muscle, including intestinal atony and atonic constipation, form a separate section. The various forms of intestinal obstruction are classified and described, with their diagnosis and appropriate treatment. The neuroses of the intestinal tract are then considered, and are divided into sensory, motor, and secretory. Affections of the rectum and anus are dealt with in a separate section. The account given of appendicitis is perhaps less exhaustive than the other parts of the book, and the discussion of the treatment, more especially in regard to the choice of cases for surgical treatment, is also less critical than its importance would warrant. Dr. Rodari reserves catarrhal cases for medical treatment, and speaks highly of opium for the purpose. Although he mentions the objection that it is liable to mask the progress of the symptoms, he does not lay so much emphasis upon this point as is customary in this country.

As a useful and authoritative work of reference in regard to diseases of the stomach and intestines we can commend this book to our readers, the more so that the sections on treatment are so full and practical.

Operative Midwifery. By J. MUNRO KERR, M.D., C.M. Glasg., F.R.F.P.S. Glasg., Professor of Midwifery and Diseases of Women, Anderson's College Medical School; Obstetric Physician, Glasgow Maternity Hospital. Second edition, with 299 illustrations in the text. London: Baillière, Tindall, and Cox. 1911. Pp. xxiv.–703. Price 21*s.* net.

IN the second edition of this excellent work Dr. Munro Kerr has found it necessary to make very few alterations. In the section on pubiotomy he expresses himself as more in favour of the operation than he did in the first edition, and now comes to the conclusion that this operation is safer than symphysiotomy, although only slightly so. He does not consider that either of these operations should be performed on a primipara, and in this he disagrees with Whitridge Williams; nor does he think that they are suitable for private practice, conclusions in which he will have the support of the majority of obstetricians. Two new illustrations of the subcutaneous method of performing this operation are given, and it is a pity that they are both inaccurate and do not agree with the text. As the author rightly says, the needle should be introduced between the labium minus and the labium majus, while in the pictures it is shown introduced between the latter and the skin of the thigh.

In the preparation of the patient before performing Cæsarean section it is gratifying to see that the author has abandoned, with rare exceptions, the douching of the vagina, upon which he laid so much stress in the last edition. Supravaginal amputation of the uterus is described in more detail, and a short account is given of the various methods of performing extra-peritoneal Cæsarean section. Dr. Munro Kerr does not believe that this operation will ever give better results in infected cases than the ordinary operation, but he is inclined to think that the uterine cicatrix may be sounder when made in the lower uterine segment than in the active contractile portion of the uterus. With this view we are unable to agree, for we regard the matter as mainly one of care in the suturing of the uterine wall. It will be noticed with interest that the author has returned to the use of silk for stitching up the uterine wall and has given up catgut, and in this we are in entire agreement with his practice.

In discussing the question of performing Cæsarean section for cases of placenta prævia the author adopts a much less antagonistic attitude towards this procedure than he formerly did, and he has himself performed the operation in one case. He suggests that in the case of an old primipara, where the hæmorrhage occurs at full term and before labour has started, and where, to judge by the condition of the parturient canal and the size of the child, delivery may be tedious and difficult, the operation may be justifiably performed. He believes that it may be possible to obtain as low a mortality as from the recognised modes of treatment in such a case. In the operative treatment of rupture of the uterus Dr. Munro Kerr is on the whole in favour of pan-hysterectomy, but thinks that simple stitching of the peritoneum and drainage may be sufficient in some cases. His own mortality from the former operation has been only 40 per cent., while after supravaginal amputation of the uterus he has had a mortality of some 60 per cent.

As was said in our notice of the first edition of this book, it is a work of the greatest possible merit, and we feel sure that

this second edition will meet with just as favourable a reception as did the first. We can heartily recommend it to students and practitioners.

Death: its Causes and Phenomena, with Special Reference to Immortality By HEREWARD CARRINGTON, late Member of the Council of the American Society for Psychical Research; and JOHN R. MEADER ("Graham Hood"), Member of the Society for Psychical Research. London: William Rider and Son, Limited. 1911. Pp. 552. Price 8*s.* 6*d.* net.

THIS book, with its black binding, its golden imprint of death, and a butterfly on its cover, and the representation of a lighted terebratula lamp on its broad back, is divided into three parts: Physiological (pp. 1–234), Historical (pp. 237–291), and Psychological (pp. 295–518). In the first part Brouardel's well-known work dealing with "Death and Sudden Death" is drawn on largely in the chapter on "The Signs of Death." On p. 20 there appears an extraordinary mistake in connexion with Kühne's well-known experiment on the visual purple of the rabbit's eye. Kühne is described as having "removed the eye, exposed the retina, and photographed it." Trance, catalepsy, and suspended animation lead on to premature burial with citation of cases and quotations, some of which may interest the credulous.

A short chapter on Burial, Cremation, and Mummification, and a longer one on "The Causes of Death," lead on to the scientific study of old age. It is stated that practically everyone dies prematurely, and that the margin of cases of natural death is small indeed. Again there are plenty of quotations. A comparison follows of the well-known views of Metchnikoff and those of C. S. Minot on this subject. "The authors having failed," we are next told, "to derive any satisfactory explanation of death from the literature of the subject and from historic research," they evolved a project of their own, which they call "the questionnaire on death." They sent a circular letter to certain persons asking the following question, "What do you consider to be the real nature of death?" and 30 pages are given to the replies and comments. We may quote part of a reply from Dr. A. C. F. Rabagliati. "Natural death is the departure from the body of anthropino-bio-dynamic. ..... The immediate cause of human natural death is nearly always such a choking up of the human house of life by excessive exercise of tropho-dynamic—i.e., polysiterism, kako-siteism and pollaki-siteism and polypotism, that anthropino-bio-dynamic is compelled to leave the body, as it is no longer a fit house for life." Mr. Carrington offers the following theory of natural death: "It is the inability of the life force to raise to the requisite rate of vibration the nervous tissue upon which it acts—its manifestation thus being rendered impossible." Mr. Meader has another theory, which is set forth *in extenso*, and then a chapter is devoted to "The Possible Unification of Our Theories." The whole winds up with a quotation from Stevenson's "Aes Triplex."

Part II. gives an account of theories of immortality, and the reader soon runs up against Spiritualism, or better, Spiritism. "The discarnate soul on entering the future world carries with it the *perisprit* or astral body which it had possessed during the period of its earthly existence," and so he is led on to "Theosophy," a "more mystical philosophy." Then come disquisitions on the philosophical and theological aspects of death, ending with the ordinary arguments for immortality. About one-half of the book is devoted to the psychological aspect, including such subjects as the moment, the hour, the pain of death, the visions of the dying, and "death described from beyond the veil," including clairvoyant descriptions and the process as described by "spirits," with liberal quotations from psychical research societies. The photography and weighing of the soul are next dealt with and illustrated by three photographs. The story of the "Testimony of Science and Psychical Research" includes well-known so-called manifestations, with all of which a public, not so credulous as formerly, is familiar—raps, independent voices, the exploits of the medium Home, and of the notorious Eusapia Palladino, clairvoyance, haunted houses, planchette writing, *et hoc genus omne*. There is no reference to Richet and the photograph he published in *Le Matin*, which elicited some very discomforting and pointed criticism. The authors wind up with the difficulties of intracosmic communication, a bibliography, and some appendices, and conclude that they have furnished "a quantity of material, all evidence of the supernormal and pointing to 'spiritism' as its most intelligent interpretation, which must be looked on as a rational theory, and accepted provisionally as a 'working hypothesis.'" These views will leave a cold world unconvinced.

The Treatment of Neurasthenia by Teaching of Brain Control. By Dr. ROGER VITTOZ. Translated by H. B. BROOKE. London: Longmans, Green, and Co. 1911. Pp. 117. Price 3*s.* 6*d.* net.

THE author of this small volume addresses himself chiefly to those who are actually suffering from neurasthenia and psychasthenia, and in this respect the book differs from the sort of therapeutic treatise which we review in these columns. He has endeavoured to simplify his language for the sake of his audience, but it is questionable whether the result is satisfactory. It is unfortunate, if the book is to be put into the hands of laymen, that it should contain matter so highly controversial as the author's hypothesis—on which, indeed, the rationale of his treatment is based—that "the physician's hand can, when placed on the patient's forehead, give him sufficiently exact indications as to the working of the latter's brain," whatever that may mean. The writer contends that through the skull one can feel a repercussion during mental activity on the part of the subject, which gives a series of pulsations producing the effect of an undulation or of a peculiar vibration. If the subject's mind wanders (though surely it does not therefore cease "working") a check in the vibrations will be felt at once. If the patient decides to will, makes up his mind to use his will, the physician feels the vibrations doubled or tripled. To enable the sufferer to regain lost control over himself and his functions, exercises of concentration are recommended, to be carried out for ten minutes every two hours, the mind being concentrated on the figure 1, or on the symbol of infinity ∞, or on different parts of the body. Then he teaches himself different methods of elimination and deconcentration, and then of concentration on an idea pure and simple. After two or three months, the author says, he should be practically well. In the author's hands the results obtained have, he says, surpassed his hopes and well rewarded his labours. In that case it would seem that he has been somewhat lucky in his subjects.

Principles of Therapeutics. By A. MANQUAT, National Correspondent to the Académie de Médecine. Translated by M. SIMBAD GABRIEL, M D. London and New York: D. Appleton and Co. 1910. Pp. 298. Price 12*s.* 6*d.*

THE author of this work remarks in the preface that there is a general impression that therapeutics is a very imperfect science. He considers that it would be more exact to say that it is an encumbered science, which is not studied with the attention it deserves, and that it is not practised with sufficient precision. He, therefore, attempts to lay down certain principles to guide practitioners in the right direction.

In attempting to define therapeutics he maintains that therapeutic science comprises two elements: (1) a knowledge, as exact as possible, of all the forces that the organism can utilise in its struggle against a morbid state, whether these forces affect the organism itself or the cause of the disease, or produce a result upon both at the same time; and (2) a knowledge of the needs of the suffering organism. He rightly points out, however, that in some instances the needs of the organism are not sufficiently understood; in others the mode of action of the measures opposed to the morbid state is not quite clear. It may also happen that both the essence of the disease and the mode of action of the remedy have not been fully explained, and he instances gout and its specific remedy, colchicum. He argues from this that a complete definition must take into consideration the empirical treatment of disease, acceptable when its efficacy is made certain by a long series of favourable observations.

Taking into account these various factors the author suggests the following definition of therapeutics: The science of the utilisable modifiers of the organism, of morbid causes and of diseases, and the art of applying their properties to the profitable correction of disturbances of health. This definition is certainly comprehensive; the use of the two words *science* and *art* is justifiable, and the extensive knowledge which is required before a satisfactory course of treatment can be laid down is duly indicated.

We have in this work an attempt to show a distinction between therapeutic actions and physiological actions, but the arguments, though interesting, are not convincing. From such chapters as those entitled "Of the Action of Medicines; Doses; the Elements of Therapeutic Individualisation"; "Influence of Environment on Therapeutics"; "Results and Variations of Therapeutic Activity Inherent in Medicines," the reader will grasp the nature of the book. Considerable information can be derived from a perusal of it. It is quite different in character from most works on therapeutics, and hence gives rise to new ideas which are instructive and suggestive.

The Climatic Treatment of Children. By FREDERICK L. WACHENHEIM, M.D., Chief of Clinic, Children's Department, Mount Sinai Hospital Dispensary, New York. London: Rebman, Limited. 1911. Pp. 400. Price 6*s.* 6*d.* net.

IT may well be asked whether the elasticity of the library of pædiatrics has any limits. We are told, however, on the authority of Dr. Frederick L. Wachenheim, that there is a definite lacuna on its shelves for a work on the climatotherapy of early life. For ourselves, after reading this book, we are not convinced of the urgency or expediency of a work on this subject. The hygienic exactions of childhood already strain to the breaking point the endurance of the full-quivered paterfamilias. His cup of bitterness would indeed be full to overflowing if he were compelled by the force of public opinion to consult a specialist before he took off his family of children for the annual "cure."

A long chapter is devoted to the general principles of climatology, and this chapter is the only one that we can honestly commend to the notice of English readers. It certainly does contain a large amount of useful information on the physiological and psychological effects of temperature, humidity, cloudiness, rain, atmospheric pressure, and phototherapy. A good definition and explanation of the pathological condition known as enervation is also given in this chapter. The term "sensible temperature," which was first given to the medical profession by Harrington, is fully explained, and its importance emphasised. On p. 7 the author explains that "the nude body of a healthy adult maintains its normal warmth of 99 degrees most easily at an air temperature of about 80," a sentence which is probably more correct in its general significance than its exact phraseology. Then there is a chapter on the Climatology of Temperate North America; there is one on Health Resorts, another on Constitutional Diseases, a penultimate one on Visceral Disease, and a final one on Scrofulosis and Tuberculosis. There is also a chapter on the Climatic Management of the Normal Child—we presume the normal American child, for we cannot think that the line of treatment recommended in the chapter would be suitable for the hardier and normal English child; at least, we feel sure it would not so appear to the normal English parent. Dr. Wachenheim has a prejudice, or shall we say a scientific objection, to cold air, cold water, and the open window, and the word "harden" is to him apparently anathema. He likes windows to fit, hot steam to warm rooms, and a temperature of about 68° F. to be maintained in the nursery. He devotes many pages to the proof not that the so-called hardening process is unsound in theory or in practice, but that his conception of the term differs from that held by "even cool-headed practitioners who have been carried away by this monstrous fad."

In Dr. Wachenheim's book the whole teaching with respect to the hygienic management of infants and children is utterly opposed to what we believe in and hold most dear in this country. We believe in cold air, cold water, and the open window, and when we are told to keep an infant indoors for the first month of its life for fear of its catching cold, we cannot help feeling that the "Climatic Treatment of Children" had better be kept out of the hands of the specialist.

Die Kinder-Seehospize und die Tuberkulose Bekampfung. (Seaside Hospitals for Children and the Fight against Tuberculosis.) By Dr. HÄBERLIN. Leipzig: Verlag von Dr. Werner Klinkhardt. 1911. Pp. 338. Price 6 marks.

THIS volume contains a large amount of information concerning hospitals for children and convalescent homes situated at the seaside in European countries. An interesting account is given of the history of the subject, due credit being given to English physicians for the part they have played in the establishment of such institutions. Attention is drawn to the writings of Dr. Richard Russell (1700–1771) and of Dr. W. Owen (1750). It is interesting to note that the latter actually published "A Dissertation Concerning the Use of Sea-water in Diseases of the Glands."

A full account is given of the various diseases in which benefit is likely to be obtained by residence and special treatment in seaside resorts—such maladies as anæmia, bronchial catarrh, asthma, various disorders of digestion and of the nervous system. The most important, however, are those conditions included under the term "scrofula." This expression is gradually disappearing from English medical literature, but is still extensively used in other countries. Baginsky defined the term as indicating a peculiar constitutional condition which afforded a favourable nidus for various diseases, especially tuberculosis. Chief amongst such conditions are affections of the glands, and it is generally accepted that the open-air life and pure air which can be obtained by the seaside are particularly favourable to delicate children who exhibit tuberculous glandular enlargements. A good account is afforded by Dr. Häberlin of the general effects of sea air, and examples are given of the excellent results obtained in a large number of cases.

A brief description follows of the various seaside institutions throughout Europe. Amongst English hospitals and convalescent homes are mentioned St. Joseph's Home at Bournemouth, the Royal Sea Bathing Hospital at Margate, and the All Saints' Convalescent Hospital at Eastbourne. Mention is also made of numerous similar establishments in

Italy, France, Germany, Russia, Holland, Austria, Belgium, Denmark, Sweden, Norway, Spain, Portugal, Greece, and Roumania.

Dr. Häberlin has been thorough in the manner in which he has carried out his work, and has collected a valuable amount of knowledge concerning the therapeutic effects of sea air and the localities in which special treatment may be obtained.

Atlas of Microscopic Diagnosis in Gynecology. With preface and explanatory text by Dr. RUDOLF JOLLY. Translated by P. W. SHEDD, M.D., New York. With 52 lithographs in colour and two textual figures. London and New York: Rebman Company. 1911. Pp. 192. Price 25*s*.

THIS atlas consists mainly of 52 coloured lithographs illustrating the chief gynæcological affections which can be shown under the microscope. The illustrations are good and well reproduced. Among the conditions illustrated are the normal mucosa of the uterus and its changes in pregnancy and menstruation, erosions of the cervix, the various forms of endometritis, carcinoma and sarcoma of the uterus and vagina, simple polypi, and two figures of vaginal secretions. As to the importance of diagnosis from the inspection of scrapings of tissue taken from the uterus there can be no question, and the subject is one of increasing value in these days of the extended operation for cancer of the cervix. After a short account of the operation of curettage a description is given of the best methods of imbedding and staining sections.

The plates are accompanied in each case by a short descriptive letter press. Dr. Jolly retains the term endometritis, even for conditions which are not actually of an inflammatory nature, for the reason that the pathology of the process, in his opinion, is not yet fully elucidated, and the plasma cells which have been considered as a criterion of the presence of inflammation are not only sometimes absent in inflamed tissues, but may be found in healthy tissues. He also maintains that the changes in the glands are in some cases so extreme that the primary morbid process must have taken origin in them It would hardly seem that this is any reason for retaining the application of the term endometritis to all kinds of very different processes.

It is possible that the original German text is well written; we regret that we cannot say the same for the translation. The translator has sacrificed style for literalness, and the result is most indifferent; indeed, it is difficult to believe in many places that one is supposed to be reading the English language. Since the main feature of the book, however, is the illustrations this is not of much importance. At the same time it certainly would have made reference to the work more attractive if the translator had succeeded in rendering the German text into something like passable English.

Lehrbuch der Ohrenheilkunde (*Text-book of Otology*). By Dr. VIKTOR URBANTSCHITSCH. Fifth, fully revised, edition. With 156 illustrations in the text. Berlin and Vienna: Urban und Schwarzenberg. 1910. Pp. 621. Price 18 marks.

THIS is the fifth edition of Dr. Urbantschitsch's well-known text-book—a fact which proves that the medical public on the continent knows how to appreciate good work. As a systematic presentation of modern otology the book, indeed, leaves little to be desired. Perhaps the English reader, spoiled by the attractive externals of his medical text-books, especially of those published across the Atlantic, may complain that, outwardly at all events, Dr. Urbantschitsch's work looks commonplace beside the picturesque volumes he is accustomed to. But when he turns to the subject-matter and finds each section handled in a style which is lucid and readable, albeit typically German in its construction, he forgets the absence of surface glitter in the solidity and worth of the matter presented to him.

In his systematic arrangement and descriptions the author is thorough, and in his expressions of opinion he is moderate and liberal. Perhaps a little more decidedness in tone on certain points would not be considered as a drawback coming from a writer of the standing and experience of Urbantschitsch. On the other hand, those who desire to become acquainted with the literature or to ascertain the clinical and experimental research undertaken in any particular branch, will find the fulness of statement and the wealth of reference of the greatest possible value.

Apart from its all-embracing exposition of the labours and opinions of other investigators, the book is further of interest in that it contains a detailed account of the author's method of treating deafness by means of the use of hearing exercises. Critically regarded, we confess that while we admit that these exercises may prove serviceable in arousing the deaf from their mental lethargy and dulness, we do not see how they can ameliorate hardness of hearing directly due to organic lesions in the ear itself. In the treatment of chronic dry catarrh of the middle ear the author speaks well of the action of galvanism, and expresses his regret that this method has fallen into disuse. Doubtless his careful advocacy of it will stimulate other otologists to give it a fresh trial. Acute suppuration of the middle ear is sometimes treated by the Bier hyperæmic method, and the author cites in its favour the opinions of several authorities. But he seems to have overlooked the publication of articles by at least one German writer of good standing, whose experience of the treatment has been decidedly unfortunate.

As has been already hinted, the illustrations cannot be commended. That representing the naso-pharynx and posterior choanæ (Fig. 30), for example, is too inaccurate for a standard work of this kind. The book is furnished with a carefully constructed index, always a welcome appearance in a continental publication.

Ueber den Selbstmord, insbesondere den Schüler-Selbstmord. (*Suicide, especially of School Children.*) Beiträge von Dr. ALFRED ADLER, Professor S FREUD; Dr. FRIEDJUNG, Dr. KARL MONITOR, Dr. REITLER, Dr. SADGER, Dr. STEKEL, Unus multorum. (Diskussionen des Wiener Psychoanalytischen Vereins.) Wiesbaden: J. F. Bergmann. 1911. Pp. 60. Price M.1.35, or 1*s* 6*d*.

THIS is the first of a proposed series of brochures containing certain of the proceedings of the Vienna Psychoanalytical Club. It is concerned with the question of suicide, more particularly among school children, a topic on which varying opinions are expressed, and it forms instructive reading.

If some of the speakers are to be credited, the school benches of to-day are peopled with hypermodernist poets, revolutionary politicians, ultra-human philosophers, and love heroes of all sorts, no doubt still in embryo, but yet the product of modern educational methods and social conditions. To the arduousness of the school *régime* is attributed the revolt of such young folk, and if there have been geniuses, from Klopstock to Nietzsche, who have been content to leave school with the reputation of "Schwachköpfe," there are others who are so morbidly conscious of their own inferiority as to end it by violent means. Due importance is attached to the working of suggestion, a factor also at work in some veritable epidemics of suicide, both recent and remote. The case is quoted of a Viennese youth who was

granted permission to examine a collection of weapons, and utilised it to select the most suitable for ending his life.

Dr. Adler has found that all neurotic patients whom he has examined psycho-analytically, including those with suicidal ideas, possessed a deep consciousness in their youth of some or other form of inferiority, either physical or mental. By way of escape from this sense of inferiority most of such individuals enter on a stormy struggle for compensation of their defects. Hence their life becomes doubled; conscious of their weakness they persevere to exhibit their strength; a state of "psychical hermaphroditismus" ensues, and it is this mental state which often leads to suicide or attempts at suicide. Professor Freud questions whether school should be held responsible for much of the youthful suicide of the day, but discovers a tendency among teachers to forget the immaturity of their charges. Instead, he says, of impressing young scholars with the pitilessness of life, the teachers should try to make school days simply a "Lebensspiel."

LIBRARY TABLE.

The Conquest of Consumption, containing Advice to Sufferers Before, During, and After Sanatorium Treatment, with Practical Suggestions for the Avoidance of Infection, and as to the Conduct of the Campaign against Tuberculosis. By E. W. DIVER, M.D. Durh., M.R.C.S. Eng., L.R.C.P. Lond., Fellow of the Royal Society of Medicine; late Resident Physician, "Belle Vue" Open-air Sanatorium, Shotley Bridge. With 6 illustrations. London: John Bale, Sons, and Danielsson Limited. 1911. Pp. 135. Price 2*s.* 6*d.* net.—This book, with a somewhat *ad captandum* title, aims to give information to sanatorium patients on various points which the author's experience has led him to regard as likely to be useful and interesting to them. It is mainly based on notes taken down by him during conversations with patients in the ordinary course of sanatorium duty. All will agree with the author that "if the war against consumption is to be carried on with success we must utilise *all* the forces at our disposal." The author discusses heredity and resistance in popular terms. In the section on Sanatorium Treatment he insists that the latter counts for much more than merely "fresh air and food." Many patients, he says, who live in healthy surroundings find it necessary to go into a sanatorium after a disappointing trial of home treatment. The advantages of sanatorium treatment he summarises as follows: Structural fitness of the patient's residence; constant medical supervision; avoidance of infection of others or of self-reinfection; rest and exercise apportioned to his varying condition; regular hours and proper food properly prepared and rightly administered; removal from the influence of injudicious friends; skilled observation of his condition helping to avert impending unfavourable changes; due allowance for temperament and disposition; guidance regarding amusements, clothing, and so forth; and immediate treatment of pathological accidents. Some serviceable advice to patients is given, and among other things an ingenious form of outdoor shelter, designed by Mr. H. Norman Marrett, and in use at Merivale Sanatorium, is described, with illustrative photographs. The floor, which is made in four quarters, each 6 feet square, for ease of transportation, consists of planks fixed on joists, which raise it a foot from the ground, thus allowing of a free current of air underneath. It is covered with stout linoleum. The roof, sides, and door are made of canvas stretched on wooden framework. For the roof the canvas, which here is nailed directly on to the framework, is treated with linseed oil, boiled and filtered, so as to render it waterproof without obstructing the passage of light. The sides are more complicated, consisting of canvas shutters so arranged that they can be raised or lowered by cords and pulleys, yet the canvas remains taut, obviating flapping and draughts. Save for purposes of privacy during dressing, it should never be necessary to close more than two sides of the shelter at once, and then only on account of wind or rain. The patient thus gets the maximum of both air and light, while protected against wind and rain. Such a shelter, it is claimed, can be constructed for from £18 to £20. The subjects of rest and exercise, food, temperature, recreation, and the duration of treatment are dealt with in a practical little book.

Congenital Dislocation of the Hip. By J. JACKSON CLARKE, M.B. Lond., F.R.C.S. Eng., Senior Surgeon to the Hampstead and North-West London Hospital, and Surgeon to the Royal National Orthopædic Hospital. London: Baillière, Tindall, and Cox. 1910. Pp. 92. Price 3*s.* 6*d.*—Opinions in this country are still divided as to the best treatment to adopt in dealing with congenital dislocation of the hip, and comparatively few surgeons here practise the bloodless method of Lorenz. One of the chief exponents of the Lorenz method in England is Mr. Jackson Clarke, and he has done well to set forth in this little volume the mode in which he carries out the operation; for an operation it indeed is, although no incision is made. He gives the reader a full account of the pathology of the condition as well as of the mode in which the operation should be performed, and of the important post-operative treatment. The author maintains that nearly 75 per cent. of these cases can be cured if operated on at a suitable age, and he gives notes of a series of 40 consecutive cases. While it cannot yet be determined what position the operation will ultimately assume, it is certain that the results obtained in some cases are extraordinarily good.

The Goulstonian Lectures on the Sensibility of the Alimentary Canal. Delivered at the Royal College of Physicians of London on March 14th, 16th, and 21st, 1911. By ARTHUR F. HERTZ, M.A., M.D. Oxon., F.R.C.P. Lond., Assistant Physician and Physician-in-Charge of the Department for Nervous Diseases, Guy's Hospital. London: Henry Frowde and Hodder and Stoughton. 1911. Pp. 83. Price 5*s.* net.—As these lectures were published in our columns in the issues of April 22nd and 29th and May 6th, and were commented on in a leading article on the last-named date, we need only repeat, for the information of those who may not have read them, that "Dr. Hertz's conclusions will be found to be full of interest, presenting as they do many new ideas, and suggesting that some of the views hitherto held as to the cause of many common symptoms are not correct."

Médications Générales. By Dr. C. BOUCHARD and other physicians. Paris: Baillière et Fils. 1911. Pp. 700. Fr. 14.—This volume forms one of the series published under the title of "Bibliothèque de Thérapeutique," the editors of which are Dr. A. Gibert, professor of clinical medicine at the Paris Faculty of Medicine, and Dr. P. Carnot, professor of therapeutics at the same Faculty. Amongst the several subjects considered in this volume are the following:—The Treatment of Certain Infectious Conditions by Sera, Vaccines, and Balneological Measures, by Professor H. Roger; the Treatment of External Parasites, by Dr. Sabouraud; the Treatment of Internal Parasites, by Dr. J. Sabrazès; the Treatment of Poisoning, by Dr. G. Pouchet; the Treatment of "Accidents" due to the Use of X Rays, by Dr. Paul Carnot; and the Treatment of Disorders of Nutrition, by Dr. R. Lépine. It will thus be seen that the range of therapeutical studies is a wide one, and includes subjects not usually found in one volume. Each article is written in a thorough and practical manner, so that as a work of reference this volume will prove of considerable value.

The Birds of the British Islands. By CHARLES STONHAM, C.M.G., F.R.C.S., F.Z.S., with illustrations by LILIAN M. MEDLAND, F.Z.S. London: Grant Richards, Limited. 1911. In 20 Parts. Parts XIX. and XX. Price 7*s.* 6*d.* each.

Part XIX. contains descriptions of the divers, petrels, grebes, shearwaters, and puffins, and with but few of these birds will many of us be acquainted at all closely, while the specimens seen in our islands are very usually immature. The puffin we may have seen in Scotland—notably in the Hebrides—in many places on the Irish coast, and in England off Flamborough Head and on Lundy Island. Of the divers, who like the puffins live by diving for small fry, although two breed in the United Kingdom, only the red-throated diver is at all generally distributed. The great crested grebe we may have seen, though not perhaps with the good fortune of Miss Medland, who draws an excellent picture of the mother taking a nestling out for a swim on her back. It is good hearing that this beautiful and graceful bird is on the increase, after indiscriminate destruction, partly in protection of fish, but partly to minister to female vanity. Mr. Stonham, however, notes that the bird is still in demand for making hats and muffs, and probably, like others who have considered this subject, he believes that appeals against the dictates of fashion have little force. The storm petrel has passed into general literature as a harbinger of trouble, and is therefore familiar to all of us by name; but how many know the origin of the word petrel? Of this bird a life-size picture is given in the characteristic skimming flight with legs down-dropped just above the waves, and from this the name "petrel" is derived through the French word *pétrel*, diminutive of Peter. For, as Mr. Stonham tells us—and here all who have gone a sea voyage will recognise the justice of his description—the petrel is rarely seen on the water, but constantly on the wing a foot or two above the surface and following the undulations, while its dependent legs give it the appearance of paddling. The imaginative sailors named it "Little Peter," because it appeared to be trying to walk on the water.

Part XX. and the closing pages of the preceding volume contain new records of rare species which have been published since this work was begun, and notes on a few new species which have been added during that time to British avifauna. The records, alas, seem sometimes to mean the death of the rarity. The remaining part of this volume contains the scientific and English indices, an admirable glossary, and a very large, if not exhaustive, bibliography. The bibliography, the work of Mr. W. H. Mullens, has not been planned as a reference to the books and papers quoted in "Birds of the British Islands," but is a compilation intended for the use of those studying British ornithology.

With the issue of these two parts the interesting zoological work upon which Mr. Stonham has been so long engaged is completed, and we congratulate him upon the successful termination of his labours. They have been labours of love as all can appreciate who have read the accurate and breezy notes on bird-life, which record his personal observations. In his illustrator he has been most fortunate, as we have on previous occasions pointed out in these columns. Miss Medland's delineations of birds in their haunts have been invariably spirited as well as accurate, and she has triumphed in a remarkable manner over the limitations imposed upon her by the use of only black and white, and by the necessary reduction in scale of many of her pictures. The *format* of the work also justifies Mr. Stonham's warm acknowledgment of the part played in the issue by the publishers, and by Messrs. Brendon and Messrs. Annan, respectively the printers and engravers.

Vocal Science and Art, being Hints on the Production of Musical Tone. The Boy's Voice; Muscular Relaxation; the Art of Deep Breathing; Elocution for Ordination Candidates. By the Rev. CHARLES GIB. With numerous illustrations, together with an Introduction, Notes, and Diagrams by J. F. HALLS DALLY, M.A., M.D., B.C. Cantab., M.R.C.P. Lond., &c. London: William Reeves. 1911. Pp. 118. Price 3*s.* 6*d.*—Mr. Gib starts off with a destructive criticism of the theories of voice-production of Mr. E. C. White. He then passes on to a consideration of the boy's voice, emphasising the importance of deep breathing and muscular relaxation as taught and practised by the Yogis of India, the aim being to cultivate "a condition of suppleness." The muscular exercises recommended by Mr. Gib are detailed in series, their exposition being illustrated by lengthy quotations from most of the classical writings on voice production. There is, indeed, little or nothing new in all this, and the book, small as it is, could have been made even smaller, as well as much more readable, if the quotations had been boiled down. Moreover, although the volume is largely made up of lectures delivered by Mr. Gib, there was surely no necessity to include in it allusions to the applause and votes of thanks which the author's remarks elicited from his audience.

The Life and Letters of Sir John Hall, M.D., K.C.B. By S. M. MITRA. With an Introduction by Rear-Admiral Sir R. M. BLOMFIELD, K.C.M.G. With portraits and illustrations. London: Longmans, Green, and Co. 1911. Pp. 560. Price 16*s.* net.—The subject of this biography, born in 1795, was a distinguished medical officer of the British Army, and formed a connecting link between what may be called ancient and modern times in the history of its Medical Service. He obtained his first appointment as hospital assistant a few days after Waterloo, and was placed on the half-pay list in 1857. During this long period he served in the West Indies, Gibraltar, South Africa, India, and the Crimea; he was principal medical officer in the Kaffir war of 1847, and of the British forces during the Crimean war. Throughout life he appears to have kept a record of his doings and experiences; from these materials and various other sources a connected story has been put together by Mr. Mitra, which affords entertaining reading in many places, and materials for history of more solid value in regard to military medical matters in the campaigns described. Perhaps some of the private letters need not have been reproduced at length in a volume intended for the general reader; but no one can fail to recognise that the subject of the biography was a man of warm feelings, cultivated tastes, of the highest character and ability, and entirely devoted to duty. The history of the Kaffir campaigns of 1847 and 1851 under Sir Harry Smith will be of interest to those who, in one capacity or another, served in the Boer war; but the chief importance of the book centres in the account of medical matters in the Crimea from 1854 to 1857. When the war broke out Dr. Hall was serving in India; he was appointed principal medical officer of the expedition, left Bombay in May, and arrived at Constantinople on June 17th. Obviously he had no opportunity of conferring with headquarter authorities at home, either military or medical, as to the plan of the campaign, its special circumstances, or the needs that would have to be provided for. The medical service of the army was in those days supposed to be chiefly concerned with the care of the wounded, and it was not realised that care for the health of the troops was of practically equal importance with the provision of food from a military point of view. Five chapters of this biography are devoted to a careful history of the campaign, supported by extracts from original documents. This is of permanent value, though

melancholy reading at this time of day. A very fair account is given of the difficulties of the medical department in 1854 and 1855—difficulties such as have recurred since, but which we hope and believe will not happen again. Referring to the magnificent work of Florence Nightingale and her staff, supported enthusiastically by public opinion and unlimited funds, Mr. Mitra observes: "Had the same means and facilities been placed at the disposal of the medical department of the army that were given to the civil establishment attached to it, they would have accomplished as much as, or more than, was carried into effect, at considerably less cost to the public, and with equal efficiency, so far as the real wants of the sick were concerned." Sir John Hall enjoyed much domestic happiness; after his retirement he sojourned on the continent, chiefly in Italy. He died in 1866 at Pisa. Lady Hall, who possessed great attractions and a charming personality, died in London in 1907 at the age of 91. The biography is rather discursive, but the collection and condensation of matter from many different sources make the book not only the record of an interesting and honourable career, but a valuable footnote to history of wider scope and importance. Sir R. M. Blomfield contributes a foreword, introducing Mr. Mitra to the reader; we cordially join in his congratulations to this talented Hindu gentleman "as being the successful chronicler of the career of an Englishman who officially connects Waterloo with the Crimea."

Transactions of the Ophthalmological Society of the United Kingdom. Vol. XXXI., Fasc. II. London: J. and A. Churchill. 1911. Price 4*s.* net.—Fasciculus II. of the Transactions of the Ophthalmological Society is above the average in interest and value. Besides cases of congenital ectopia lentis reported by Mr. J. Stroud Hosford, irideremia by Mr. H. B. Grimsdale, a peculiar granuloma of the retina by Dr. Frank G. Thomas and Mr. George Coats, it contains several exceptionally good papers. Particularly noteworthy is Mr. J. Herbert Fisher's paper on the Pituitary Body and Lesions of the Optic Chiasma. Nine cases are described exhaustively with diagrams of the fields of vision and in several cases skiagrams showing erosion of the dorsum sellæ turcicæ. The signs and symptoms of the disease are minutely recorded and are reviewed in the light of Cushing's experimental work on dogs. Particular interest attaches to the encouraging results obtained by treatment with Merck's tabloids of pituitary extract and Armour's extract of the anterior lobe of the pituitary body. Another paper of outstanding merit is that on the Histology of Papillœdema, by Mr. Leslie Paton and Dr. Gordon Holmes. The authors support the now generally accepted view that "choked disc" is an œdema and not a primary inflammatory condition. The fundamental cause is increased intracranial pressure, which is transmitted to the intra-vaginal space. Dr. A. Hill Griffith has added three cases of optic nerve tumour to the literature of this comparatively rare condition.

First-Aid Charts. By EDWARD C. IBOTSON, M.B., B.S. Lond. Bristol: John Wright and Sons, Limited; London: Simpkin, Marshall, Hamilton, and Kent, Limited. Four charts. Price 6*d.* each, or 1*s.* 6*d.* the set of four.—These first-aid charts are an attempt to reduce by tabular form to easy accessibility the main principles of first-aid treatment in emergencies. They are intended to be hung up to the public view in factories, mines, schools, colleges, nurseries, public institutions, and other similar places. The four charts cover respectively (1) Emergencies, accidents, and poisoning; (2) fractures, dislocations, and sprains; (3) wounds and hæmorrhage; and (4) insensibility or unconsciousness. They would probably be of service for ready reference to one who had already some training in the broad principles of first-aid, and to the student as a means of review.

JOURNALS AND MAGAZINES.

Jahreskurse für Ärztliche Fortbildung. (*Annual Post-graduate Review.*) Munich: Lehmann. Price 16 marks per annum.—The May number of this journal is devoted to Diseases of the Nervous System. Professor Edinger deals with the treatment of some of the common forms of nerve disorder. Insomnia in most of its varieties can be effectively relieved by a proper regulation of diet, baths, and exercise. In other cases hypnosis is of great value, although it is so seldom employed. Lastly, the rôle of drugs in the treatment of sleeplessness is fully considered. Headache is the next subject in this article, and the great importance of correctly ascertaining the cause before proceeding to treatment is insisted upon. In dealing with various functional disorders of the nervous system, the relative importance of a proper treatment of the body by diet and rest, and of the mind by suggestion, in different cases is carefully discussed. Again, in the treatment of neuralgia the point of first and greatest import is the distinction between cases of primary and secondary origin. In dealing with epilepsy, the various theories which relate this disease to metabolic disorders are briefly reviewed, and then a consideration is given to the signs of a localising character which indicate the possibility of surgical treatment. In the case of tabes and other degenerative cord lesions, prolonged rest is regarded as being very important in the early stages. Professor Vogt contributes a short article in which the psychological basis of nerve disorders is considered, while Professor Binswanger follows with a somewhat abstruse discussion of the principles of morbid psychology. In this an endeavour is made to relate the various forms of insanity to disorders of sensation, perception, and the association of ideas. Professor Berger deals with the treatment of organic nerve diseases, the chief subjects touched on being the rôle of salvarsan in cerebral syphilis, the indications for, and results of, surgical treatment of cerebral tumours and abscesses, the value of lumbar puncture in tuberculous meningitis, and the various toxic nerve disorders, such as those caused by morphia and alcohol.—The June number is devoted to the Diseases of Children. Professor Pfaundler discusses the various tendencies to disease or diatheses of childhood. That which used to be termed a scrofulous tendency is now termed an inflammatory diathesis. This is carefully described both in its latent and manifest stages as it affects the skin, mucous membranes, and nervous system. Such various conditions as eczema intertrigo, laryngitis, and pyloric spasm are regarded as being due to the same underlying cause. Next, the status thymo-lymphaticus is treated of, and its relation to cardiac disorder discussed. The third great disease tendency in childhood is termed the "arthritic diathesis." A consideration is given to the relationship existing between these different diathetic conditions to one another, and also between them and the disorders of the nervous system. Dr. Theodor Gött gives an excellent article on the convulsions of childhood. He divides them first into those which are functional and those which are symptomatic, and then deals separately with the convulsions occurring within the first two years and those of later childhood. Infantile tetany is regarded as due to a hyper-excitability of the nervous system, and the relation of this to rickets and other metabolic disorders is considered. There are irregular contractions not only of the voluntary muscles, but also of the visceral musculature, notably of the heart, intestine, and bladder. The symptomatic or organic convulsions of infancy must be very carefully distinguished from those which are merely functional, because the underlying cause can often be remedied if it is recognised in time. The chief causes are tetanus, septic diseases, pneumonia, meningitis, and

birth traumas. In discussing prognosis it is pointed out that less than a third of the children who suffer from "convulsions" ever develop into normal adults. The proper regulation of the diet is considered to be the most important point in the matter of treatment, and as regards drugs, chloral hydrate in 0·5 gramme doses given by the rectum is held to be the most valuable. The convulsions of childhood later than two years of age may be due to tetanus, idiopathic epilepsy, hydrocephalus, cerebral tumour, infantile paralysis, syphilis, or may arise reflexly from disease of the sensory organs, or from disorders of digestion and metabolism. These various forms are all briefly described.

The Yellow Fever Bureau Bulletin. No. 2. June, 1911.—Since the publication of the first number of this new periodical its editor, Sir Rubert Boyce, we regret to state, has died, and Dr. Harald Seidelin, formerly professor of pathology and bacteriology in the Medical School of Merida, Mexico, but now attached to the staff of the Liverpool School of Tropical Medicine, has been appointed to fill the post. The new editor brings to his task not only special scientific knowledge of the subject, but also practical experience of the disease. The first item in the present number of the *Bulletin* is a sympathetic obituary notice of Sir Rubert Boyce, to which is appended a reproduced photograph of the late editor. A series of reports of recent occurrences of yellow fever in West Africa and in the West Indies are then given, after which Dr. Seidelin contributes a very exhaustive original article extending to some 19 pages on the Treatment of Yellow Fever Cases. This is followed by some reviews of lately published books or pamphlets which relate to the disease in one or another of its various aspects. The current *Bulletin*, like its predecessor, concludes with a bibliography. This second number fully maintains the standard set up by the first, and in our opinion it must prove of great interest to all who are concerned in the diagnosis, treatment, or prevention of yellow fever.

Quarterly Journal of Microscopical Science. Edited by Sir E. RAY LANKESTER, K.C.B., F.R.S., with the coöperation of ADAM SEDGWICK, M.A., F.R.S., SYDNEY J. HICKSON, M.A., F.R.S., E. A. MINCHIN, M.A., F.R.S., and GILBERT C. BOURNE, M.A., F.R.S. August, 1911. London: J. and A. Churchill. Price 10*s.* net.—Mr. W. E. Agar, D.Sc., considers the spermatogenesis of Lepidosiren paradoxa from material obtained during an expedition to the swamps of the Paraguayan chaco, undertaken primarily for the purpose. Mr. Geoffrey Smith continues his studies in the experimental analysis of sex, by a consideration of the cause of the fluctuations in growth of the fowl's comb. In this he essays to demonstrate that correspondence of the comb increase with egg-laying is invariable, that these rapid fluctuations are characteristic of hen birds, and that they are due to a fatty infiltration of the central core of the comb taking place just before egg-laying commences. At this time the blood becomes charged with the fatty material conveyed to the ovary for the formation of yelk, the excess of this being deposited in the comb. Mr. C. H. Martin and Miss Muriel Robertson publish some further observations on the cæcal parasites of fowls with some reference to the rectal fauna of other vertebrates. The authors state that in recent years there seems to have been a tendency to regard the life-cycle of parasitic flagellates as a subject on which the most hazardous speculations can be put forward, and these, unfortunately, crystallise only too soon into the well-known protozoon life-cycles of the zoological text-book. Though they do not feel justified in putting forward a complete life-cycle in the case of any one of the forms they describe, they consider themselves right in publishing the results obtained, because (1) their preparations were always made from the wall of the cavity containing the parasite and not simply from the content of the cavity, so that they have obtained a more complete series of division of the active forms than earlier workers, and have also got an interesting series of new stages; and (2) owing to the ease with which it is possible to obtain newly hatched chicks and keep them free from all animal parasites, they have obtained really valuable data as to the course run by new infections of these forms. They have obtained evidence which they believe justifies them in dividing the animal parasites found in the cæca of fowls into the following species:—(1) Chilomastix gallinarum (*sp. nov.*); (2) Trichomonas gallinarum (*sp. nov.*); (3) Trichomonas eberthi (*sp. nov.*); (4) Trichomastix gallinarum (*sp. nov.*). They describe their technique, and discuss each of the four forms named. Mr. Charles L. Boulenger discusses some points in the anatomy and bud-formation of Limnocnida tanganicæ (African fresh-water jelly fish).

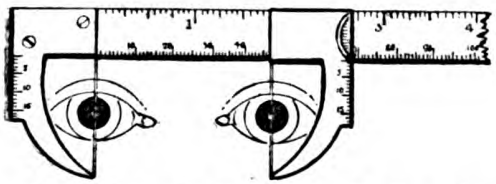
The Quarterly Journal of Medicine. Edited by WILLIAM OSLER, J. ROSE BRADFORD, A. E. GARROD, R. HUTCHISON, H. D. ROLLESTON, and W. HALE WHITE. Vol. IV., No. 16. July, 1911. Oxford: At the Clarendon Press. Subscription price 25*s.* per annum; single numbers 8*s.* 6*d.* each net.—In this number, under the title Some Points in Relation to the Etiology of Auricular Fibrillation, Dr. C. E. Lea describes his investigations, which lead him to the conclusions that auricular fibrillation can be regarded as a definite clinical entity, which in 56·6 per cent. of cases is preceded by rheumatic or choreic disease, mitral stenosis being the most frequent lesion. In non-rheumatic cases auricular fibrillation is found in 43·4 per cent., the most frequent lesion being cardio- or arterio-sclerosis. The age incidence of mitral valve disease, with or without preceding rheumatism, was 38·2 years; of cardiac sclerosis 53·9 in rheumatic, 56·9 in non-rheumatic cases. Females were more frequently subject to valvular disease, males to cardio- or arterio-sclerosis. Of all cases of auricular fibrillation, 32·8 per cent. occurred in cardio-sclerosis, 31·3 per cent. in mitral stenosis, and 23·8 per cent. in cardiac dilatation. Influenza occurred in 39·3 per cent. of non-rheumatic cases. Electro-cardiagraphic records confirm the polygraphic records in all cases examined. Dr. J. D. Windle, in considering the Relationship of the Heart Beat to Pulsus Alternans, concludes that the observations he details, while they lend some support to the view of Hering that in alternate heart beat a partial systole of the ventricle occurs, also show that in alternating pulse it is not always possible in clinical cases to determine the fact of alternating heart action. Dr. P. N. Panton and Dr. H. L. Tidy, in a paper on the Analysis of the Gastric Contents, deal with the routine examination of test meals in a series of cases, and make an inquiry into the various methods of examining test meals and the meaning of the results obtained. They conclude, among other things, that all the methods commonly in vogue are approximately accurate when the free acidity is either normal or above normal, and inaccurate when it is low. The Prout-Winter method, however, they consider inaccurate in any circumstances. They do not agree that the estimation of so-called "active" hydrochloric acid according to Willcox's method is either accurate or profitable. Phosphates introduce a fallacy common to all the methods they have investigated. They suggest that the phosphates are secreted into the cavity of the stomach when the gastric mucous membrane fails to elaborate free hydrochloric acid from the mixture of phosphates and chlorides brought to it from the blood. They consider Günzberg's reaction and the estimation of total and dimethyl acidity to be as accurate as more elaborate methods, and to supply all the assistance and information which can be reliably obtained from examination of the gastric contents. The Systolic Pressure as

Different Points of the Circulation in the Child and the Adult is compared by Dr. Leonard Findlay, who concludes that during childhood and youth the systolic arterial pressure is fairly uniform at different points of the circulation. In adult life the peripheral systolic pressure is lower than the central, and the difference between them increases with age. Finally, the difference greater than normal between the central and peripheral systolic pressures in cases of hypertension, from disease or experimentally produced, supports the idea that the behaviour of the pressure and its variations depend upon changes in the elasticity of the vessel wall. Dr. Peter F. Holst and Dr. A. H. Monrad-Krohn report two cases as a contribution to the study of the function of the *A.-V.* bundle. Dr. W. Hale White reports five cases of Essential Renal Hæmaturia, which have been followed for much longer periods than almost all other published cases, with the moral that the outlook is good and that the disease does no harm apart from the loss of blood. In a critical review of the Use of Tuberculin in So-called Tuberculous Glands, Dr. George E. Waugh concludes that any estimate of the value of injections of tuberculin in the treatment of enlarged glands must be invalidated by the fact that no proof that the glands were tuberculous can be offered until the glands have been subjected to operation. The most important factor in the treatment of chronic glandular enlargement with a view to the avoidance of extensive operative interference is the complete elimination of all primary foci of infection. The use of the guillotine in the tonsils is one of the most serious causes of failure in the treatment of enlarged glands. Wright's bacillary emulsion has not been proved to be of any value, though it is probably harmless. In enlarged glands which on removal proved to be tuberculous, thickening of the operation scar frequently occurred, but disappeared under a course of injections of tuberculin.

New Inventions.

NEW OPHTHALMIC CALIPERS.

WITH the increasing necessity for the correct centring of spectacles there comes the demand for a rapid and accurate measurement of the ocular base line. It is no longer found sufficient, as in former days, to take a rough measurement of the interpupillary distance. The instrument shown in the accompanying illustration was devised for the purpose of



measuring the base line in working with the registering form of diaphragm test, and the new calipers have proved, after a year's work, to give this measurement with the greatest expedition and with an accuracy that meets the stringent conditions of that test for binocular vision. In experimental forms these calipers were exhibited to the Ophthalmological Society in 1909 and 1910; they are now made by Messrs. G. Culver, Limited. The raw material used is steel, and the workmanship is excellent. Briefly the method of usage is as follows. The patient faces a distant light, either a window or lamp, and looks at it with both eyes; the images of the light are seen upon the corneæ and mark the visual axes. The surgeon faces the patient at arm's length, places the rule upon the patient's brows, and sights the fixed wire over the image on the patient's right eye. Then the other wire is slid over the image on the left cornea and carefully sighted. The surgeon sights the patient's right eye with his own left eye and *vice versâ*. In measuring the base line for near vision the procedure is the same, but the light is put over the surgeon's head at the requisite distance and the patient looks at it. The vertical scales on the jaws are for the purpose of measuring the vertical displacement of lenses for the correction of hyperphoria. The trial lenses are tilted until the defect as measured with the scale test card in the diaphragm test is corrected, the rule is held horizontally across the patient's brows, and the depression of the lens of one side as compared with the other read off.

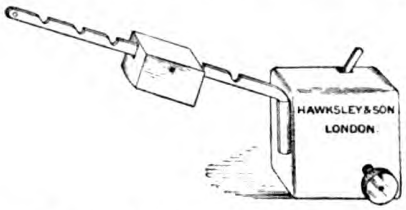
Harley-street, W.

A BALANCE-WEIGHT FOR THE CLINICAL POLYGRAPH.

PROBABLY not a few beginners with the clinical polygraph have found among their other troubles a difficulty in keeping the spring of the sphygmograph in contact with the radial artery when the "arm" carrying the tambour for collecting the pulsations from the neck is placed *in situ*. The weight of this is apt, more especially in the case of slender wrists, to tilt the sphygmograph outwards, and thus to remove the instrument from the artery and to cause the loss of the radial tracing. If, in order to avoid such a result, the wrist-strap of the sphygmograph is drawn more tightly, the consequences are unpleasant for the patient, and the undue pressure thus occasioned may, once again, diminish or suppress the arterial excursion. After various attempts to get rid of this annoyance I have at last hit upon a simple mechanical contrivance which may perhaps



be of service to other workers. The principle of it is the provision of a weight in opposition to the force or leverage exercised by the "neck tambour" and by the "arm" which carries this tambour, and this in such a fashion as to allow graduation of the balancing or resisting force without altering the amount of pressure exerted on the radial artery by the spring and pad of the sphygmograph. To secure these ends a socket is fixed on that side of the box containing the clockwork of the sphygmograph opposite to the one carrying the tambour "arm," and into this socket is fitted an angled rod carrying a moveable weight and notched so as to allow the weight to be temporarily adjusted at different points, the arrangement being, in short, similar to a steelyard. If after the sphygmograph has been attached to the wrist the tambour arm and the balance weight are placed in position the whole apparatus remains perfectly steady, and thus the inscription of the two tracings is much facilitated. The balance-weight is readily added to the present pattern of Dr. Mackenzie's clinical polygraph, and is not without value, at least in occasional instances, in the use of the sphygmograph pure and simple. It has been made for me by Hawksley and Son, 357, Oxford-street, W.

Harley-street, W. C. O. HAWTHORNE, M.D. Glasg.

INTERNATIONAL MONUMENT TO CESARE LOMBROSO.—The central committee in Rome charged with the carrying out of this undertaking has just received the sum of £62 from the Scottish committee organised with the same object under the presidency of Lord Guthrie, one of the judges of the Court of Session. The central committee also announces contributions to the movement from continental committees whose interest in the founder of the science of "criminal anthropology" seems proportioned to the recrudescence of "hooliganism," represented abroad by the "apaches" of France, the "teppisti" of Italy, and the "Mano Nera" of the United States.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 9, 1911.

Inebriety and Alcoholism.

LEGISLATIVE enactments, like individual enterprises, are apt occasionally to produce effects so different in their nature and influence from what their authors had promised and expected that it may be a matter of difficulty to recognise the original intention in the final result. The Inebriates Act of 1898 is a very striking instance of this sort of miscalculation. The object of the Act, as was generally understood when it was placed on the statute book, was to give effect to the view, which had been strongly voiced by medical opinion, that the pathological factor in inebriety ought to be considered in the treatment of inebriate offenders. Instead of regarding intemperance merely as a vice, which when it led to antisocial acts was if anything an aggravation of their iniquity and as such entailed a proportionately heavier penalty, the law now set itself to recognise that inebriety might be due to a condition of disease, the existence of which in a delinquent should take him out of the category of ordinary criminals and should bring him under curative treatment rather than penal discipline. Unfortunately, however, in framing the measure which was to embody this very sound view the legislature thought fit to adopt a plan which appears to have been inspired by totally different and quite incompatible principles. Though proceeding, as we have seen, from the assumption that the condition to be dealt with was one of disease, it rigorously reserved to the administrators of the law not only the prescription of the treatment but also the making of the diagnosis. So strictly, indeed, has this singular system been adhered to that, though a medical certificate is required as part of the machinery for committal to an inebriate reformatory, the official form on which it has to be furnished omits all reference to the patient's inebriety; the certifying physician is invited to express an opinion as to the intemperance of the patient's grandmother, but the intemperance of the patient does not concern him and is wholly a matter for the superior diagnostic skill of the police. It was hardly to be anticipated that the results attained by these very novel methods would be of a kind to encourage further experiments on similar lines. And that they are most distinctly not of such a kind is made abundantly clear in the very interesting but rather pessimistic report of Dr. R. W. BRANTHWAITE on the working of the Inebriates Acts (1879 to 1900) during the year 1909, which has just been published.

Dr. BRANTHWAITE, whose annual reports are usually distinguished by a freshness of idea and a careful style not too common in blue-books, has devoted the greater part of his latest volume to a general disquisition on the nature of inebriety and the characteristics of the inebriate. In this connexion, of course, it has to be remembered that these terms are used in a somewhat special sense determined by the very peculiar legislation which has provided the material for Dr. BRANTHWAITE'S words. Thus, what we are to understand by an inebriate in this report is simply an inmate of an inebriate reformatory, and inebriety in the same way can hardly be defined more exactly than as a liability to become such an inmate. It will be seen from this that Dr. BRANTHWAITE'S description of the condition in question and of its victims suffers under the disadvantage that he has had to seek out biological and psychological characters in a category of individuals defined by a purely legal criterion, and a very rough-and-ready one at that. His task, in fact, is somewhat like that of a naturalist who should be called on to furnish a scientific description of the horse, the horse being first defined inclusively and exclusively as any animal found in a stable. It is necessary to point this out, because Dr. BRANTHWAITE does not appear to have indicated it with quite sufficient clearness, and the unwary reader might easily fall into the error of supposing that the report purported to give an account of alcoholism and alcoholic subjects in the medical sense, and not simply a description of the sort of individuals who get committed to inebriate reformatories under the existing law. Such a misapprehension of its real purport would be the more regrettable because it would interfere with the due appreciation of the lesson which this valuable report can teach regarding the defects and limitations of the Inebriates Act of 1898. For it may be safely affirmed that the fact most clearly brought out by Dr. BRANTHWAITE'S inquiry—and the fact, we may add, of most practical importance—is the complete failure of that Act to touch even the fringe of the problem of chronic alcoholism. The evidences of this are manifold. In the first place, we have the fact that of the total number of "inebriates" committed to reformatories during the last ten years—3309 in all—only 542, or 16 per cent., were men, although, as is well known, the incidence of chronic alcoholism, as measured, for instance, by the mortality from delirium tremens and other manifestations of chronic intoxication, is far higher in men than in women. Again, we observe that in only 9 per cent. of the reformatory patients is even a probable history of delirium tremens forthcoming, and this despite the inclusion of several doubtful cases. Further, we learn that it is rare to find any evidence of permanent tissue change resulting from alcoholic excess in these individuals; and, again, that they display a "conspicuous absence of disease of the intestinal tract, disease of the kidneys, and gout."

These latter facts lead Dr. BRANTHWAITE to express some doubt as to the soundness of current medical teaching which attributes many organic and functional disorders to the action of alcohol taken in excess, but unless we are to adopt the same attitude of scepticism with regard to the general belief in the alcoholic origin of

delirium tremens, it seems more natural to suppose that the reason why the inmates of reformatories are relatively free from such disorders and have so rarely suffered from delirium tremens is simply that although they are inmates of reformatories they are not chronic alcoholics. And that this is the correct interpretation is placed beyond doubt by a fact to which Dr. BRANTHWAITE has called attention in previous reports and which he again emphasises now—namely, that some 65 per cent. of these so-called inebriates are of obviously defective mental capacity, and the remaining 35 per cent. are to be described as normal, "not because defect is absent, but because it is less marked." We are dealing, in short, in these cases with individuals who drink—when they do drink—because they are diseased, and not with individuals who are diseased because they drink. Cases of the latter sort—cases, that is to say, of chronic alcoholism—do not find their way to inebriate reformatories; and inasmuch as these are the cases which in their early stage are curable, and as, moreover, they are the source of the major part of alcoholic crime, the failure to reach them is the real origin of most of the adverse criticism to which the Inebriates Act has been subjected by recent observers.

It might do much to diminish the prejudice against reformatories for inebriates, which clearly exists, and accounts for the condition of things revealed in Dr. BRANTHWAITE'S report, if we adopted a more precise phraseology and ceased to use such terms as inebriety and alcoholism as applying indifferently, on the one hand, to cases of chronic poisoning in relatively normal individuals, drinking under the influence of environmental and industrial conditions, and, on the other hand, to cases of congenital mental deficiency in which a proneness to take alcohol and an intolerance of its action are indications of a general cerebral fault. Certainly the recognition of a distinction between these classes would clarify our ideas as to the treatment of each one of them. The denomination of "alcoholic" might with advantage be restricted to the former, and that of "inebriate" to the latter category—if, indeed, there is any good reason for differentiating in the mass of the feeble-minded a special group under this distinctive heading. Inasmuch, however, as these so-called inebriates do not seem to differ in any important characteristics from the rest of the mentally defective, and as it is not suggested that they require, by reason of their supposed inebriety, any different system of treatment and discipline, the need for such a differentiation is not apparent. It is, in fact, more likely that by introducing artificial divisions of this sort we should only promote the confusion of ideas and multiply the practical difficulties which stand in the way of an effective solution of the problem of the feeble-minded. For the moment, at all events, the most important conclusion to be drawn from Dr. BRANTHWAITE'S interesting review of his official work is that we are still as far as we were before 1898 from any satisfactory system of dealing with curable cases of alcoholism. Such cases, in which institutional treatment of a sufficiently continuous character might prevent the degradation of a useful worker into a burden on society and a danger to its security, are not, it seems, amenable to the Inebriates Act.

The Nutritive Value of Bread.

THE report recently presented to the Local Government Board by Dr. J. M. HAMILL on the nutritive value of bread made from different varieties of wheat flour is a very careful review of all the work that has been done upon the subject from earlier times down to the present date. In spite, however, of this admirable effort to collect evidence on the controversial matters raised in the so-called "standard bread" movement, there still remain, in Dr. HAMILL'S own words, "numerous points of uncertainty" which require settlement, while he further observes that "any inferences which may now be drawn from observed facts are necessarily liable to require considerable modification as knowledge of the physiology and chemistry of nutrition advances." This is a thoroughly wise reservation. Nevertheless, Dr. HAMILL has elucidated many of the questions at issue, and the unprejudiced and painstaking way in which he has collected the materials in his report makes future work easier. His observations have the merit of logic and good sense. Much analytical work done at the laboratory of the Local Government Board by Dr. G. W. MONIER-WILLIAMS adds value to the report.

The differences in nature and in nutritive value between breads made from varying classes of flour are not of much importance to the average adult with whom bread is only one out of many varied constituents of the dietary. A diet which consists principally of bread, from whatever grade of flour it may be made, is not in accordance with the human needs. But in those unfortunate cases in which practically bread, and bread alone, provides the daily sustenance, there would clearly be an advantage in the use of bread made from flour of the "entire" wheat class, since such flour secures a somewhat larger quantity of mineral matter and of suitably combined phosphorus and other substances, as yet unknown, which may prove to be factors of importance in the processes of nutrition. It is true, however, that bread is our chief source of starchy food, and even the person who is free to choose a mixed dietary eats it as a necessary accompaniment to, or vehicle for, the proteins and fats which make up his meal. But whether we are considering those with whom bread is the principal food, or only those to whose meals bread is a valuable accessory, there is a psychological aspect which deserves more attention than it has received. What better meal is there, or what meal that responds more closely to the physiological requirements of the body than bread, butter, and cheese? And how greatly is its enjoyment added to by bread with the unmistakeable taste that we call "nutty"? There is a complete harmony existing between the flavour of good cheese and the flavour of good wheaten bread. But the bread-and-cheese meal, so palatable when the constituents have individual and irreproachable characters, while it becomes nasty if the cheese be nasty, is at once uninteresting and unappetising should the bread be conspicuously without flavour. The true bread flavour makes all the difference between our enjoying and not enjoying our meal, and, as is well known, when the enjoyment of food is eliminated real food value is greatly discounted. The simple and scientific meal of bread, butter, and cheese can be completely spoilt by indifferent bread, even though

the other ingredients are satisfactory. It follows that, regarding bread as an integral part of a dietary, it should still have appetising qualities.

The report contains reference to physiological experiments bearing upon the influence on nutrition of certain constituents of "standard" flour which are absent in white flour. Experiments on pigeons and rats are quoted showing that both thrive better when fed upon standard flour than upon white flour. In the case of the pigeons the birds fed only upon white bread lost weight and suffered from peripheral neuritis, though the addition of yeast to the diet was sufficient to restore them to a healthy condition. We are not prepared with an explanation of this fact. In this connnexion Dr. HAMILL refers, as was inevitable, to the work which has been done on the etiology of beri-beri. A diet consisting of rice from which the skin or cuticle has been removed may give rise to beri-beri, a condition which manifests itself by polyneuritis and other symptoms. It has been shown that polyneuritis analogous to that which occurs in beri-beri can be produced by rice which has been deprived of its cuticle by milling. Moreover, if the "offal" which has been removed from rice, and which amounts to 10 per cent. of the grain, be returned to the rice no polyneuritis occurs. SCHAUMANN concludes that a deficiency of certain organic phosphorus compounds in the grain deprived of its skin has profoundly modified metabolism. Considerations of this kind show the necessity for further work on the subject of the nutritive value of bread, and we may be sure that it will soon be done. The value of Dr. HAMILL'S report lies in the fact that he has drawn attention to a number of important but undeveloped chemico-physiological questions in regard to our commonest and most familiar article of food. The time and energy which he has devoted to his task have been fruitfully spent. He has done much towards laying bare what are the actual facts of the case, and has furnished arguments of the most urgent kind for further research.

The Improvements in the Naval Medical Service.

IN the Students' Number of THE LANCET, published on August 26th, under the heading of the Naval Medical Service, we were able to indicate a certain number of changes in the organisation of the Service which were immediately to take place. These changes were announced in detail last week in a Circular Letter issued by the Admiralty under the nominal date of August 11th. The net result of the new regulations for the Service will be, we think, more satisfactory to those belonging to the Service than could be gleaned from the announcement in the *Gazette* of August 18th, and the recruiting of officers for the Service should therefore be easier. For the pay in every grade has been improved, while the particular care that is being paid to post-graduate instruction will ensure for the Service such good clinical and scientific instruction that any members of it, who may choose to avail themselves of the opportunities of leaving the Service for civilian practice, will find themselves perfectly well equipped in many directions. This is particularly the case as for the future the second post-graduate course, taken after 14 years' service, will in some degree permit the study of special subjects at the officer's own choice. The first part of the Circular Letter enumerates the alterations in pay and allowances of the Service which have already been published in THE LANCET. The salaries of the Medical Department of the Admiralty are advanced, so that the emoluments of the Medical Director-General, the Deputy Director-General, and the Assistants are all slightly raised. The increase of pay granted in any particular rank, however, is not of so much importance as the more considerable increase of pay which attends each successive step upwards towards and in the more important appointments. This seems to us a reasonable recognition of the fact that the more experienced an officer is the more highly he should be paid. The Director-General can now reward officers for good work as he never could before, and junior officers have far better prospects than their predecessors had, and far more incentive to keep their knowledge up to a high standard.

The two most important alterations effected in the Service by the new regulations are undoubtedly the establishment of a naval medical school for the training and post-graduate instruction of the officers, and the recognition of the medical officer of the senior flagship of a fleet as the Principal Medical Officer of that fleet. The first of these alterations was well known to be in contemplation, and the second is one for the justice of which there has been much contention in our columns. As was expected, the new naval medical school will be established at the Royal Naval College at Greenwich in close proximity to the Dreadnought Seamen's Hospital and the London School of Tropical Medicine, and in a position, as the Circular Letter says, to carry out its educational and scientific work in close connexion with those establishments. When it becomes one of the medical schools of London it will be in touch with all the schools attached to the metropolitan hospitals and with the Army Medical School at Millbank, while there are already in existence at Greenwich many of the laboratories that will be required for the new work. Additional laboratories for medical research are to be provided in the college buildings and furnished with the necessary equipment and scientific apparatus. The work now done at Haslar will not be discontinued, although a proportion of that work and the appliances in connexion with it will necessarily be transferred to Greenwich. At the Naval Medical School at Greenwich one Fleet-Surgeon with a special allowance of £150 a year will be appointed as Professor of Bacteriology and Clinical Pathology, and another Fleet-Surgeon, with the same special allowance, will be appointed as Professor of Hygiene. The latter officer will reside in the college and be in charge of the studies of the medical officers undergoing their course at Greenwich. A medical officer will also be retained at Haslar for the instruction of Acting Surgeons, and he, too, will receive, as he does at present, an allowance of £150 per annum for this duty. The new school at Greenwich will be utilised as soon as it is open for the instruction of Acting Surgeons immediately after their entrance to the Service. The course of instruction of these officers being now lengthened from

four to six months, the first two months of the course will be passed at Greenwich, the period being devoted to the study of tropical medicine, bacteriology, clinical pathology, hygiene, and skiagraphy; the remaining four months will be passed at Haslar, as at present. It is unnecessary to point out to our readers how valuable a school of instruction and research in the vicinity of London for the Naval Medical Service must prove to be. We hope that its institution and the improved post-graduate courses will increase the efficiency of the Service, while the better pay should attract recruits.

The recognition of the medical officer of the senior flagship of a fleet as the Principal Medical Officer of that fleet is made in the following terms:—

He will be appointed on the staff of the Commander-in-Chief and wear an aiguillette. He will act as the Commander-in-Chief's principal adviser on all medical and sanitary matters connected with the Fleet, and it will be his province to report to the Admiralty periodically upon the arrangements for the treatment of the sick, the sanitary conditions, and the state of the medical appliances in the various ships; also to supervise and report upon the arrangements for the treatment and transport of wounded, the instruction given in first aid, and other matters as he may be directed. He will have direct access to the Commander-in-Chief, and be in a position to propose for his consideration any measures likely to conduce to the efficiency of the medical organisation of the Fleet, and he will be directly responsible to the Commander-in-Chief for keeping him informed on these matters generally.

This is not only an acknowledgment of the responsible and dignified position held by the officer who is to be regarded as the Principal Medical Officer of the Fleet; it is a direct compliment to the official and scientific standing of medicine, and an alteration in the regulations which must materially improve the health and medical treatment of the seamen of the fleets. As such we welcome the reform warmly.

Annotations.

"Ne quid nimis."

THE HOUSING OF HOMELESS WOMEN.

THE National Association of Women's Lodging Houses, which was instituted on Feb. 24th, 1909, and has its headquarters at 4, Tavistock-square, London, has recently issued the report[1] of the proceedings of its Third National Conference. The object of the association is to link together societies and individuals interested in shelters for women and girls, to disseminate information and promote legislation on the subject, and to institute local committees. It was announced that the deputation, instructed by resolution of the preceding conference to wait on the Housing Committee of the London County Council, presented to that body on Feb. 15th of this year a statement on the need for providing proper accommodation for women, and suggesting the provision of houses, each to accommodate about 100 women, in the following selected areas: Tabard-street or Newington, Drury-lane, King's Cross, Hoxton, Notting Dale, and Pimlico or Vauxhall. The deputation was well received, and a subcommittee of the London County Council was formed to inquire into the whole question of provision of suitable accommodation for women in London. The Congress was participated in by the Associated Societies for the Protection of Women and Girls, the Federation of Working Girls' Clubs, the Mansion House Council on Health and Housing, the National Council of Public Morals, the National Housing and Town Planning Council, the National Union of Women Workers, the National Vigilance Association, the Travellers' Aid Society, the Women's Industrial Council, and the Young Women's Christian Association. The Lord Mayor having opened the Congress, the Duchess of Marlborough took the chair and delivered a thoughtful presidential address, in which she met an objection often raised—that lodging houses for women would tend to destroy home life—by pointing out that the woman worker, for whose needs provision was sought, was already actually or practically homeless. "Those who speak so eloquently," she said, "against what they term the breaking-up of the home, have perhaps not always seen the home they profess the provision of decent lodgings for girls would destroy." A paper on the Need for Women's Lodging Houses, by Mrs. Mary Higgs (read, in the unavoidable absence of the author through illness, by Miss Taylor), pointed out that more women than girls seem to feel the need of such provision, and endorsed very strongly a suggestion by Miss Alston that lists should be compiled of safe lodging homes, with information as to whether they are restricted to a certain class or age, or are open for women of all ages, or will receive girls in urgent need of shelter. Mrs. Higgs is optimistically convinced that through the provision of such accommodation the problems of womanhood, the sweated worker, the deserted wife, the widow, the feeble-minded, and the inebriate will one by one be met. The point to be aimed at, according to Dr. J. F. J. Sykes, medical officer of health of St. Pancras, is proper provision for privacy and modesty, with homely supervision, but without over-regulation—a point in which we find ourselves in hearty accord with him. A brief summary of the powers of local authorities to provide municipal dwellings for women was given by Alderman W. Thompson, in which he showed that local authorities may acquire through the Local Government Board not only land, but also money to enable them to erect lodging houses or hostels, flats or cottages, to supply them with the necessary fittings, and to convert existing buildings into lodging houses. Mrs. Bramwell Booth, however, was antagonistic to the Government or municipal institutions for single women, being convinced that they constitute a real menace to the home, and she pleaded for increased opportunity and greater support for private enterprise. She described what one private hostel for women, established and maintained by the Salvation Army, had accomplished, and argued that to offer human beings provision for their physical and temporal need alone was to treat them no better than horses were treated. Mrs. Hopkinson, discussing the housing of educated girls and women earning their living in London, pointed to the results attained by Brabazon House, Limited, as showing that financial as well as other success is possible under the initial conditions of care in construction and expenditure, a capable architect, and a well-chosen small board of directors. Interesting papers were also read by Mrs. Charles Morrison, Miss Margaret Ashton, M.A., and Mrs. MacKinnon. That there is need of provision for homeless women and girls is hardly likely to be disputed; but, as in regard to other crying needs arising out of our present social system, considerable statesmanship is essential if the need is to be satisfactorily dealt with without entailing other, and, perhaps, equally serious, evils.

UNIVERSITY OF ST. ANDREWS: ITS QUINCENTENARY.

CENTENARIES, a laudable innovation in the nineteenth century, are in danger of becoming an "institution" in the twentieth. Certainly they seem, oftener than not, to be celebrated on very slight provocation. Scotland has of late years made herself conspicuous by the number of these commemorative functions, of which, however, the more justifiable have been those of her seats of learning. In 1884 she celebrated the tercentenary of her post-Reformation University at Edinburgh; in 1901 the "ninth jubilee" of Edinburgh's pre-Reformation sister at Glasgow; in 1908 the quater-centenary of her seat of learning, also pre-Reformation, at Aberdeen; and now she is commemorating the 500th birthday of the eldest of the four, her "Mater Studiorum" at St. Andrews, founded, like the two last-named, by Papal bull. Ungrateful indeed would she be if she showed herself insensible to the obligations under which those foundations have laid her, owing to them as she does the opportunities and the discipline which have enabled her sons to compete in the "struggle for existence" with the more highly favoured of their contemporaries; compete, moreover, not unsuccessfully, while receiving in return a refinement and a distinction not to be gained in the somewhat rugged conditions into which they were born. Poverty, so far from being the "curse" it is considered to be, is, to a really masculine people, a distinct blessing, fraught with incentives to work, to self-reliance, to honourable ambition. "With the bayonet of necessity at her back," as one of her typical sons expressed it, Scotland has faced difficulties and stormed positions from which, without such *vis a tergo*, she would have shrunk, and though many have fallen in the struggle, the survivors have been numerous enough to encourage relays of recruits, pressing forward under the rubric—

"Nil mortalibus arduum est."

Just four centuries ago, her ecclesiastics and her *noblesse*, the two dominant forces in her kingdom, were so evenly balanced that neither could afford to give a point to the other, while the Crown, as *tertius gaudens*, played them off against each other. On Sept. 9th, 1513, she sustained, at the hands of England, one of her most disastrous defeats on Flodden Field, her king and wellnigh all her nobility among the slain. What happened? The Church, relieved of the check imposed on her by the aristocracy, plunged into excesses which so alienated the people that when the Lutheran wave swept over Britain it found Scotland prepared to meet it more than half-way. A clean sweep was made of the Papal authority and the Papal religion. The people, left to themselves—the *noblesse* being represented by minors, when not wiped out—were thrown back on their own resources, and through their leader, John Knox, greater as a statesman than as an ecclesiastic, secured this advantage, to wit, that wherever there was a parish church there must be a parish school. From this institution Scotsmen are prone to date their rise in the world, and not without reason, preparing the humblest of their sons for the professions at the essentially democratic seats of learning which the national poverty could provide, and thus tapping a social stratum which, under more favourable conditions, would have lain inert. Poverty again, before the union with England in 1707, sent the professionally-minded Scot to the Continental schools, particularly those of Holland, and prepared them for the practice of the most cosmopolitan of liberal callings—that of medicine. An impulse was thus given to their study of the healing art and its preparatory "institutes" which made their native schools, particularly that of Edinburgh, the resort, even of Englishmen, for the continental discipline and methods not to be had at home—a fact which explains the prosperity of those schools even from a financial point of view, till even St. Andrews, remote from opportunity for clinical observation and research, used her character of "University" to grant degrees in medicine to outsiders—a step in contrast to her otherwise unmercenary record. What happened? At first the Royal Commission which recognised this "departure" limited to the number of ten in any one year the duly qualified practitioners to whom the St. Andrews degree might be given, at the same time supplementing the local professoriate with examiners from other schools. This restriction was *motivé* as a check on the multiplication of graduates, not connected with St. Andrews, but drawn mainly from England and Ireland, a multiplication which raised the University capital from £2278 in 1834 to £15,300 in 1868. In 1862 alone as many as 604 received the *summi in medicinâ honores!* This abuse called loudly for reform, and the Commissioners of 1889 ordained that the University could grant no degrees in medicine except to her own *alumni*. From this enactment dates the enormous development of the medical school at Dundee, now almost continuous with St. Andrews by the Tay bridge—another proof of Scottish power to bow to circumstances and rise to new ideals. This development will take rank with any of the more creditable episodes in the history of St. Andrews and reveals a spirit and an initiative of the best augury for her future.

AN EXPOSURE OF CONTRACT PRACTICE.

IN the *National Review* for August there appeared an interesting criticism of the National Insurance Bill from the pen of Mr. Adolphe Smith, who is well able to speak with authority on the evils of the contract system of medical practice, for it is an open secret that he carried out the first-hand investigations whose results were printed in THE LANCET and republished under the title of "The Battle of the Clubs." Mr. Smith not only knows his subject but he has also the gift of apt and lucid exposition. He feels very strongly that contract practice, which he describes as "the tallyman system applied to professional services," is inherently bad, that friendly society control of medical practitioners has been degrading, and that a national scheme founded on the past charity of the medical profession must inevitably break down. All this he sets forth in telling phrases which no educated layman can fail to grasp. His historical review of the situation is particularly impressive. He traces back the contract system to "the great wave of humanitarian feeling which swept Europe in the forties," and shows how the penny-a-week method of payment, which was acquiesced in at first by medical men out of charity as a means of relieving immediate local distress, steadily developed and hardened until the charitable aspect of the matter became forgotten and the prosperous artisan club member came to believe that this sum was adequate payment for professional services. The author aims directly at the public ear, and he puts his case with so much force and point that we hope his article will be very widely read, though it was written before the intention of the Government was known not to vest the distribution of medical benefits in the friendly societies. Mr. Smith contends with great justice that the contract system must be even more harmful to the patients than to their medical attendants. It is a pity, he says, that there are some practitioners who have made quite a good thing out of it; instead of denying that a penny a week could possibly pay for professional services and drugs, many of them set to work to organise their practices in such a manner as to make it pay. Mr. Smith has seen contract medical

practice at close quarters in all its forms, at its best and at its worst, and he can find little or no good in it. Contract work in practice, he maintains, is quantity instead of quality; the friendly societies and all such medical aid organisations are the natural economic antagonists of the medical profession; and any scheme of national insurance which sought to perpetuate and expand the club system would have been utterly unsound. The author strengthens his arguments by illustrations from abroad: he shows how in all industrial countries there is an inherent hostility between the medical profession and the friendly societies, and how the practitioners of the Continent have been anxiously looking towards this country in apprehension lest their own progress may be hampered by the example of Britain. This analysis of the medical opposition to the Insurance Bill as originally framed is in sharp contrast to some of the misleading rubbish which has appeared in other lay columns. It is to be hoped that the lesson it teaches will be pressed home upon the public at large, who cannot then fail to understand the reason for the attitude of the medical profession towards the friendly societies, and the view which the Government has taken of that attitude.

CHRONIC ACETANILIDE POISONING.

THERE are probably few powerful drugs which are consumed more widely and indiscriminately than the coal-tar analgesics, judging from the number of quack remedies which contain one or more members of this group of substances. Moreover, a very large amount is taken in the form of compressed tablets, bought only too easily over the druggist's counter. Considering the well-known toxicity of antipyrin and its congeners, it is a matter for surprise that more has not been written about the poisonous effects of long-continued abuse of these compounds. Dr. Herman C. Gordinier, in recording two cases of chronic acetanilide poisoning in the *Boston Medical and Surgical Journal* of August 10th surmises that part at least of this deficiency is due to errors in diagnosis made possible by deception on the part of the patient. His first patient was a woman of 30, whose flat denial of any drug habit led at first to a mistaken diagnosis, until by careful observation a supply of five-grain tablets of acetanilide was discovered among her belongings. Then it was found that she had for four years been taking a daily dose of 50 to 75 grains. She complained of great weakness, palpitation, faint attacks, and shortness of breath. There was a striking cyanotic tinge of the lips, ears, fingers, and toes. The conjunctivæ were pale and cyanosed, and the skin of the whole body was bluish-black. This colouration varied from time to time, its periods of greatest intensity coinciding with an increase of the subjective symptoms. The heart was dilated, and there was a murmur of mitral incompetence. The spleen was enlarged and tender, the liver less so. An examination of the blood, at the first interview, discovered an erythrocyte count of 9,200,000 per cubic millimetre, with some poikilocytosis, but no other striking change. Several years later, however, the count had fallen to 2,142,610 per cubic millimetre. The colour of the blood was bluish-black. There were several points of superficial ulceration in the skin, one on the front of the left leg, another on the pinna of the ear, and a third in association with the scar of an abdominal operation. A very careful examination of the urine was made. The specific gravity was 1026; the colour, brownish-red when it was passed, changing later to an inky black. It reduced Fehling's solution and yielded dextrosazone crystals with the phenylhydrazine test. The ethereal sulphates were greatly increased. There were no blood pigments, the abnormal colour being due to urobilin. Glycuronates were probably, but not certainly, present. A rapid and continuous improvement began as soon as the tablets were stopped. After a period of excitement and sleeplessness the patient lost her craving for the drug and was apparently cured. The second patient was also a woman, 52 years of age. In her case there was a varying cyanosis, and both liver and spleen were tender and enlarged. The blood and urine displayed much the same changes as in the first case, and there was a similar cardiac enlargement. From his study of these cases and those recorded in medical literature Dr. Gordinier concludes that the continuous ingestion of acetanilide or allied products creates a perfectly definite syndrome of cyanosis, with enlargement of heart, spleen, and liver, a definite blood picture and characteristic urinary findings; and that there is an equally definite acetanilide habit.

THE ACTION OF THE TROPICAL SUN ON MEN AND ANIMALS.

IN the temperate zone a prolonged period of excessive sunshine may have, as we pointed out in these columns on August 19th, some effect upon the mental attitude and physical condition of the inhabitants. Probably the abnormal amount of sunshine which we experienced in the first half of August had some share in bringing to a climax the late remarkable epidemic of strike mania. To work in the blazing sun with the thermometer at 90° F. or more was calculated to produce a state of intense nervous irritability and exasperation of mind, leading to distortion and exaggeration of grievances on one side and impatience at complaints on the other. In the tropics the native worker, if left to follow his own bent undisturbed, seeks the shade and avoids exertion during the heat of the day. Animals also instinctively keep under cover while the sun is shining. Even the monkey, a native of the tropics, making its home in the recesses of the forest into which few of the sun's rays can penetrate, seldom exposes itself to the sunshine for more than a few minutes at a time. Dr. Hans Aron of the Philippines University, Manila, who has lately made an experimental investigation into the action of the tropical sun on men and animals, asserts that the monkey, notwithstanding the fact that it is a native of the tropics, withstands exposure to the sun's rays worse than any other animal with which he is acquainted, not excluding the white man himself. Dr. Aron, in a paper in the *Philippine Journal of Science*, sets out the provision which Nature has made to enable the body to resist the injurious effects of excessive sunshine. The animal body possesses the capability not only of regulating its heat production from the combustion of foodstuffs (chemical heat regulation), but also its loss of heat from convection, radiation, and water evaporation (physical heat regulation). Normally the thermal effects of the surroundings are compensated for, either by a suitable transference of heat to the surroundings or by the conservation or production of heat within the body, so that the body temperature within narrow limits should remain practically the same. There are, however, bounds to this power of regulation. If the body be heated too intensely, or if the loss of heat be inhibited, the latter will accumulate and the body temperature will rise. High air temperatures alone do not change the body temperature so long as the latter can be regulated by the loss of sufficient heat through water evaporation. If the relative humidity of the air be high and therefore the evaporation of water lessened, the loss of heat is inhibited. The radiation from the sun is an important factor. The majority of substances, including the animal body, have a much higher coefficient of absorption of heat than the air has, and therefore they become hotter in the sun than does the surrounding air. A dog placed in the sun soon exhibits symptoms of heat-hyperpnœa; its respiration becomes quicker,

the tongue hangs out, and the saliva increases and drops from the mouth. As dogs have no sweat glands the evaporation of water, which in man is effected by the secretion of sweat, is replaced in these animals by increased evaporation from the surfaces of the lungs, mouth, and especially the tongue. Monkeys, like dogs and rabbits, have no sweat glands, and their physical heat regulation is confined to the reduction effected through water evaporation from the lungs and mouth by increased respiration. Their capacity to evaporate water in this way is limited. Monkeys exposed to sunshine in Manila died within 70 to 80 minutes, but the shade afforded by an open umbrella held over an animal was sufficient to save it from any injurious consequences caused by the sun's rays. Dr. Aron summarises his conclusions as follows. Under climatic conditions, even in the cooler seasons of the year in Manila, animals, such as rabbits and monkeys, which by nature have only a limited power of physical heat regulation, or animals the physical heat regulation of which is artificially inhibited (e.g., by tracheotomy in dogs), die if exposed to the sun, the body temperature rising to febrile heights. If the animals are protected from the rays of the sun, or if the increase of heat due to radiation from the sun is compensated for by an increased loss such as would be brought about by a strong breeze, then the animals experience no ill effects. Insolation of the skull alone is without result if the body temperature is kept within normal limits. The post-mortem appearances in animals which have died as a result of insolation show decided hæmorrhagic lesions of the meninges in the brain, and in monkeys in the heart. In animals without sweat glands the subcutaneous tissues are warmed by the radiated heat from the sun to temperatures above those compatible with life. The human skin if exposed to the sun is warmed to about 3° or 4° C. above the normal skin temperature, an increase to the normal body temperature being, of course, prevented by evaporating sweat. The brown skin of Malays, while theoretically absorbing more heat in the sun, shows a smaller rise in temperature in the tropical sun than the skin of white men in similar circumstances. In explanation of this it is suggested that an earlier and better water evaporation by perspiration takes place in the coloured man, who is said to have larger and better developed sweat glands. A man with a coloured skin is, if this be an anatomical fact, in a better position as regards physical heat regulation than the man whose skin is white.

MEMORIAL MEETINGS FOR DEPARTED MEDICAL MEN.

A BEAUTIFUL custom has been followed for some years past in St. Louis, U.S.A., which cannot fail to elevate the ideals of the medical profession and cement the bonds of professional fellowship, and which might be followed elsewhere with great advantage to the guild of medicine. There are somewhere about 2000 medical men in that city of three-quarters of a million population, and of these more than a third are members of the St. Louis Medical Society. It is the custom of that society to set aside one Sunday afternoon in each year for a mass meeting of the profession in commemoration of those of their number who have died during the preceding year. The proceedings consist of sacred music, a brief address by the President of the Medical Society, and a short appreciation of each of the departed physicians in turn, delivered by someone well acquainted with him in all his relations of life. A few passages from the memorial address by Dr. Robert Schlueter, President of the St. Louis Medical Society, uttered at the last memorial meeting, will serve to illustrate the spirit that animates these pious gatherings. After stating that nine of their number had passed away during the year, Dr. Schlueter said that rarely did it fall to a medical man's lot to have his name and deeds remembered much beyond those who knew him while he was alive. Of those who stood aloof from the common herd, some did so because of superior merit, but many others because of exceptional opportunity or favourable chance, so that the work of men who seemed mediocre should not be under-estimated if it apparently had nothing to give it extraordinary distinction. There were many men whose true worth only became known after the bias of their contemporaries had been removed, while many were of

> "Those who never sing,
> But die with all their music in them,"

and very few of these could expect to be rescued from obscurity, as was John Bassett by the searching and keenly observing eye of William Osler. Dr. Schlueter thought that no injustice would be done by regarding his late associates without much discrimination and bestowing upon each of the dead co-workers more or less equal consideration. In this liberal spirit the commemorative addresses were made, and we feel constrained to admit that for simple, direct feeling they are each and all eloquent. It is a remarkable thing that such a spirit of fraternal unity should have come about in a city which, more perhaps than any city in the United States, was a few decades ago notorious for its professional enmities and strife. We repeat, therefore, that the practice is not only a beautiful one, but one which must make for harmony and brotherhood, and we should gladly see it followed in other communities.

THE STERILISATION OF WATER WITH ULTRA-VIOLET RAYS.

THE sterilisation of town water-supplies by means of ultra-violet rays is now becoming more and more popular. The question may fairly be said to have emerged from the experimental stage, at least in France. Along the whole Riviera, from Marseilles to Mentone, general uneasiness is felt in regard to the water-supply. In most places the water is said to be quite good, but it is also very generally acknowledged that it might accidentally be contaminated. If, therefore, some extra precaution could be taken this would be very welcome, and at Nice and Monaco, for instance, the authorities are only waiting for some conclusive verdict or argument that will enable them to decide whether they should sterilise their water-supply with ozone or by the ultra-violet rays. The very popular summer resort, the town of Saint Malo, is not waiting any longer, but has positively decided to adopt the ultra-violet rays for the treatment of its water-supply. At Isle-sur-Sorgues, near Avignon, in the Vaucluse department, waterworks on this principle are nearly finished, while at Maromme, near Rouen, they are completed and in working order. Maromme is the centre of half a dozen small suburban districts or villages close to Rouen, with a total population of 25,000 inhabitants. It has a water-supply derived from the chalk containing only from 6 to 82 bacteria per cubic centimetre. Strict precautions are taken to prevent the contamination of the catchment grounds. But, nevertheless, it only needs an accident or neglect to expose the water intake to serious dangers. Therefore Messrs. Puech and Chabal,[1] who represent the Westinghouse Cooper Hewitt Company of London and Paris, were entrusted with the establishment of quartz mercury lamps for the sterilisation of the Maromme water-supply. An installation has been constructed to treat 25

[1] See THE LANCET, Dec. 17th, 1910, p. 1784.

cubic metres per hour, or 600 cubic metres (132,000 gallons) in the 24 hours. But it is first necessary to filter the water, so as to make sure that it shall be clear enough to permit the easy penetration of the ultra-violet rays. For this purpose a very simple filter suffices, and in this case a filtering surface of 50 metres square is more than enough. This surface is divided into two filters. A layer two feet thick of clean fine sand is placed on a bed of small gravel, and this rests on perforated tiles carefully cemented together. From under the filters the water flows into small tanks or reservoirs that feed the sterilising apparatus. This consists of two distinct parts. There is an automatic valve contrived for the purpose of preventing the passage of the water whenever the electric current ceases. So long as the current keeps the lamp burning the same force closes the valve. But the moment the lamp goes out and the production of ultra-violet rays ceases, then the valve opens. The water thereupon runs through it to waste and does not mix with the purified town supply. When, on the other hand, the electric current is working satisfactorily and this valve is closed, the water passes close to three sides of the lamp and is thus exposed three times to the purifying action of the ultra-violet rays. From calculations made of the expenditure of electric energy necessary and of its cost the impression is gained that the employment of ultra-violet rays is decidedly cheap. As for its efficacy, the bacteriological laboratory of Rouen examined 14 sets of three specimens each taken at different dates between Feb. 13th and March 24th this year. First there was the water fresh from the intake. The number of bacteria per cubic centimetre varied from 6 on March 1st to 86 on March 15th. The colon bacillus was sometimes absent, but generally there were 20 to 30 per 100 cubic centimetres. The second set of samples was taken after the water had passed through the filters, and the number of micro-organisms varied from zero to 14. The colon bacillus had entirely disappeared except from a sample taken on Feb. 25th, when 5 were discovered in 100 cubic centimetres. The third specimen was that of the water after it had been exposed to the action of the ultra-violet rays. In every one of the 14 specimens the water was absolutely sterile; there were no bacteria of any description whatsoever, and certainly no colon bacilli.

HARVEY AND CÆSALPINUS.

THE first volume of a work on physiology by Professor Luciani of Rome has just appeared in an English translation. The contents deal with the circulation and respiration, and incidentally Professor Luciani upholds the claims of Cæsalpinus as against those of Harvey with reference to the discovery of the circulation of the blood. Dr. D. Fraser Harris, in a paper appearing in the August number of the *Edinburgh Medical Journal*, takes up the cudgels briskly on behalf of Harvey. He brings forward nothing new; in all probability there is nothing to bring; but his paper is a useful marshalling of facts. It is but rarely that any scientific discovery can be said to be entirely due to the man who first gives it to the world, but he it is to whom the name discoverer rightly belongs. Thus Adams had calculated the probable position of Neptune before Leverrier, but, owing to the procrastination of the British Astronomer Royal and the want of an acurate star chart, it was Leverrier who obtained the credit, although Adams is now universally allowed to have an equal share in the glory. After the discovery it was found that the planet had been seen before on more than one occasion. Something similar was the case with Harvey; many of his predecessors had noted facts in connexion with the circulation—the Hippocratic writings contain the words περιόδος αἵματος, Galen knew that the arteries contained blood, and Fabricius, Servetus, and Cæsalpinus had all observed phenomena which might have led to the discovery. But Harvey unquestionably was the first to draw the correct deduction from the observations of his predecessors and himself—namely, that the blood does make a complete circuit—and to him therefore rightly belongs the name discoverer.

ACUTE LEUKÆMIA.

THE researches of Ehrlich upon the morphology and staining reactions of the leucocytes of human blood have led to a most accurate examination of the blood in health and disease, with the result that a more or less definite blood picture is now recognised for many infective diseases and for pathological conditions of the blood-forming organs. The original classification of Ehrlich into granular and non-granular leucocytes with their subdivisions—the former into neutrophile, eosinophile, and basophile, and the latter into small lymphocytes, large mononuclear leucocytes, and transitional forms—has been more or less generally adopted, although numerous alternative names have been applied to most of the varieties. The dualistic view of Ehrlich that the granular forms originated in the bone marrow and the non-granular forms for the most part in lymphoid tissues has, however, been much debated, and, although it is now generally accepted, there are a few authorities who believe in the existence of non-differentiated parent cells from which both varieties are derived. Ehrlich's original view has been so far modified as to admit that there is a non-granular stage of the myelocytes or marrow cells, which subsequently develop into the granular forms of the blood. This non-granular form has been called a myeloblast by Nägeli. These cells may appear in the blood under pathological conditions, and since they are difficult to distinguish from the pathological forms of the large lymphocyte, it is obvious that the interpretation of blood films in which they occur may give rise to difficulty. An interesting and critical examination of this question is given in a monograph[1] upon acute leukæmia by Dr. Albert Herz, who has observed eight cases in the wards of Professor Kovacs of Vienna, six of which came to necropsy. He also gives an exhaustive summary of the literature of this interesting and grave condition. He points out that the nature of these cases cannot always be established from the clinical and hæmatological characteristics only, since the blood picture is variable and aleukæmic forms of leukæmia exist. The pathological histology of the blood-forming organs is the most important criterion. Dr. Herz recognises an acute lymphatic and an acute myeloid form of the disease, and believes that the features of this condition rather tend to support the dualistic than the unitarian views as to the origin of the leucocytes. The disease in the majority of cases begins suddenly, usually with fever, associated with great weakness, headache, and pains in the back and limbs. Not infrequently sore-throat or ulceration of the mouth occurs early in the disease, and also marked hæmorrhagic tendencies. Asthenia and cachexia quickly supervene, and are profound. The changes in the mouth comprise, in addition to ulcerations, necrosis and membranous or gangrenous affections. The lymphatic glands and the spleen are enlarged, but much less as a rule than in the chronic forms. Death may occur from hæmorrhage, from secondary septic infections, from exhaustion, or from pulmonary complications. In the acute lymphatic form the lymphocytes are increased, the relative increase being of greater diagnostic importance than the absolute number. They may form 90 or more per cent.

[1] Die Acute Leukämie (Acute Leukæmia). Von Dr. Albert Herz. Leipzig and Vienna: Franz Deuticke. 1911. Pp. 184. Price M.4.50 or Kr.5.40.

of the total. As a rule the pathological large lymphocyte preponderates, though sometimes large and small cells occur in approximately equal numbers, and in rare instances the small lymphocytes preponderate throughout. The pathological large lymphocyte is described by Dr. Herz as a large cell with a large round or oval nucleus and with homogeneous, basophile protoplasm. Sometimes there occur very large forms called giant lymphocytes and others with an indented or lobulated nucleus. Degenerative appearances are not infrequent. All these cells can only be regarded as of lymphoid origin if transitional forms between them and the mature small lymphocyte are present, otherwise the distinction from acute myeloid leukæmia is very difficult. The characters of the blood in this condition are markedly different from the typical blood picture in chronic myeloid leukæmia. In acute myeloid leukæmia the eosinophiles and mast cells may be entirely absent, and there are abundant atypical undifferentiated immature forms of the granular leucocytes: viz., the neutrophile myelocytes and their non-granular early stage—the myeloblasts of Nägeli. In some cases these cells may be the chief ones present. Various small differences in staining reactions are described between the large pathological lymphocyte and the myeloblast, but of these Dr. Herz has only found one at all reliable—viz., that the nuclei of the latter stain very well with the tri-acid stain, whereas the nuclei of the former do not. The pathological histology of the two forms of acute leukæmia is different and approximates in each case to the appearances in the chronic forms. In the acute lymphatic form there is a deposit of lymphocytes in various tissues, whereas in the acute myeloid form there is infiltration of the tissues and organs with cells of myeloid origin, including Nägeli's myeloblasts. The disease has been regarded as a tumour formation, closely related to sarcoma by some authorities, as an infective process by others. Dr. Herz inclines to the latter view, but regards a single or specific cause as improbable, since he believes that various agents have the power to produce changes in the hæmapoietic organs resulting in leukæmia.

NATIONAL INSURANCE IN GERMANY.

IT seems to be the fate of the medical profession that its interests should be persistently ignored by the framers of national schemes of insurance. At the time that our Chancellor of the Exchequer was placing his original measure before the British people the whole of the German laws on the same subject were under discussion in the Reichstag, and great hopes were entertained that some provisions would be included destined to remedy the many defects in the working of the measure as far as the medical practitioner is concerned. One of the principal demands put forward was the inclusion of a definitive and adequate mode of remuneration for medical services in the place of the existing system of bargaining with each sick club. These hopes have been rudely dispelled; in fact, the position has been distinctly rendered worse by increasing the income-limit of the insured from £100 to £125, and medical men throughout the German Empire now recognise that self-help and a strong organisation afford the only means of safeguarding their personal as well as professional interests. It has been decided to form an organisation of medical practitioners with the object of obtaining full recognition of the demands hitherto ignored. A central board, we are informed by a German correspondent, has been formed to which the task of enforcing these demands will be entrusted, and the following line of action has been decided upon. In the first place, all contracts between medical practitioners and sick clubs must be submitted for approval to the central board. To further the free choice of doctors commissions and arbitration boards are to be formed, and steps taken to prevent the treatment of sick-club patients by unqualified persons. Of particular interest is the decision to enforce the usual fees in the case of sick-club patients with an income between £100 and £125. This is due to the fact that the extension of the income-limit will include within the scope of compulsory insurance a large number of persons which hitherto formed a not inconsiderable portion of the medical practitioner's private practice, and their loss will necessarily entail serious financial results. It was also decided to consider the establishment of a uniform standard of fees for professional services, applicable throughout the German Empire, rendered to members of sick clubs.

THE REVISION OF THE PHARMACOPŒIA.

A FURTHER report has been issued by the Committee of Reference in Pharmacy to the Pharmacopœia Committee of the General Medical Council. It includes the results of work accomplished by the committee from January, 1910, to May, 1911, and with it has been published a supplementary report dealing with work which has been done subsequently. It may be assumed that these two reports are the last of the series to be issued by the committee, and the Pharmacopœia Committee now has at its disposal a mass of valuable material which will form the skeleton of the monographs in the next edition of the Pharmacopœia. The newly issued reports deal chiefly with the monographs from Jalapa to Zinci Valerianas, and also include an appendix giving the processes for (1) the determination of the acid value of fixed oils, fats, waxes, and resins; (2) determination of the saponification value of fixed oils, fats, waxes, and resins; (3) determination of the iodine value; (4) determination of the unsaponifiable matter; (5) saponification process for volatile oils; and (6) acetylation process for volatile oils. In many of the monographs important alterations are suggested.

ON SOME EFFECTS OF SALICYLATES AND ASPIRIN.

THE unpleasant effects of salicylates in overdoses or in hypersusceptible persons are well known, and the fact that aceto-salicylic acid, or aspirin as it is more generally named, sometimes causes gastric pain and other evidence of digestive derangement, especially if given with alkalies, is also a matter of common knowledge. We publish in this week's issue of THE LANCET two papers referring to certain aspects of the action of these drugs which are worthy of note. The first of these is by Mr. H. Ewan Waller, who gives notes of three cases, which he suggests indicate that the salicylates, including aspirin, have a powerful influence against the activity of the thyroid gland. He first discusses the theory that the ordinary symptoms of fever are due, at any rate in part, to increased activity of the thyroid gland brought about by poisons or by toxic agencies of various kinds. This theory, as he points out, was expounded in an interesting article published in THE LANCET of Nov. 9th, 1907, by Dr. Arnold Lorand, who reviewed the evidence, partly experimental and partly clinical, upon which it was based. Mr. Waller then discusses his own cases, the first of which was a patient with acute tonsillitis and febrile manifestations. After considerable doses of sodium salicylate and of compound tincture of cinchona, a subnormal temperature, a low pulse rate, and obstinate constipation supervened—symptoms which, together with a low blood pressure, Mr. Waller attributes to depression of thyroid activity. His second case was a woman with "minor

thyroid inadequacy" and chronic constipation. The last-named symptom was found to be increased by aceto-salicylic acid, administered for lumbago. The increased constipation is interpreted as due to exaggeration of the thyroid depression brought about by the drug. The third case was one of Graves's disease, in which considerable improvement occurred after treatment by aspirin. Mr. Waller's suggestions can at most be regarded as tentative, even though the thyroid theory of the nature of fever be, as he states, a tempting one. The complex chemical interrelations of the various organs of the body through the agencies of hormones and internal secretions constitute some of the most striking results revealed by modern experimental research, and have opened up a fruitful field of therapeutic possibilities. Numerous ingenious speculations as to these functions have been propounded, among them the thyroid theory of fever, but it is important to bear in mind, as Mr. Waller obviously does, that they are theories. His conclusion that aspirin may possibly be useful in the treatment of Graves's disease is worthy of trial, but its success would by no means establish the accuracy of his explanation. In this connexion it is interesting to note that salicylates in large doses have been recommended in the treatment of thyroiditis. The other note to which we refer is a brief account of two cases showing swelling of the face and urticarial wheals after taking aspirin in moderate doses. The swelling of the face in both instances appears to have been considerable, so as to make the patients almost unrecognisable, and in both the tongue became enlarged. The condition appears to have been of very short duration. In view of the alarm to which such a condition must give rise, it is important to bear in mind the possibility of its being due to aspirin, and Dr. Alexander Brown's note should be useful in calling attention to the matter.

JOHN LEYDEN'S CENTENARY: CIVIL SERVANT AND PHILOLOGIST.

THE British Empire, in its colonial expansion particularly, owes much to its medical men, not only in the strictly professional sphere, but in others more or less open to cultured intelligence when thrown into situations appealing to its exercise. The court physician at oriental seats of government, the medical missionary in semi-civilised or partially explored countries, the practitioner attached to outlying posts in colonies or dependencies, the surgeon serving in the army, navy, or mercantile marine—to each and all of these the British name or prestige is signally indebted for initiative or achievement redounding to its interests, immediate and permanent. Sir John Macneill as body-physician to the Shah of Persia, Dr. Livingstone at missionary stations in Central Africa, Sir Joseph Fayrer or Sir Harry Ker-Innes at their respective posts in Hindustan, a Huxley or a Spencer-Wells serving at a naval command in tropical or sub-tropical waters, are but a few out of many conspicuous examples of the medically qualified professional man utilising his opportunities or employing his leisure for the advancement of his country's interests in the positions or the circumstances in which his lot happened to place him. A book, indeed, fascinating, even romantic in its tenor, might be written on what Lord Morley calls the "flexibility of adaptation" displayed by the British medical man in situations or crises evoking his intervention, proving, *inter alia*, that the mind scientifically trained, and quickened by contact with nature in its many phases, animate or inanimate, individual or social, can "take occasion by the hand" and utilise its energies to the benefit of humanity in ways as profitable as they are unexpected. The recent celebration of the centenary of John Leyden's death did not fail to remind his compatriots of the "flexibility of adaptation" in question, conspicuous as, in his short-lived career, he became, not only for medical work in the Madras Presidency, but also for biological, ethnographical, and philological study among the races of the Far East, which made him in those subjects an authority of world-wide recognition and acceptance. A Borderer contemporary with Sir Walter Scott, who has portrayed his strongly marked and complex personality in vivid colours, he so utilised his opportunities as to become the most brilliant oriental scholar of his time, giving an impetus to ethnological and linguistic research which had its effective continuation in the work of another and a kindred spirit, also of medical training and experience, Dr. James Cowles Prichard, whose monograph on the Celtic races long held the field as the most learned contribution to a supremely difficult subject. Sir George Douglas, who, as a cultured and sympathetic Borderer, presided at the Leyden commemoration, in the course of his speech referred to other fields in which the hero of the day excelled, conspicuous among these being that of legendary poetry, in which Leyden was not only a collector and commentator, but no mean performer himself, as Scott and Campbell, his contemporaries, have testified. So true it is that the plastic and multiform mind loses nothing by its early concentration on science, particularly when the science in question is that devoted to the study of mankind in its numberless phases, whether of health or disease.

THE AMERICAN PROCTOLOGICAL SOCIETY.

THE Thirteenth Annual Meeting of the American Proctological Society was this year held at Los Angeles, California. Dr. George J. Cook, of Indianapolis, the President, was in the chair. Among papers of importance one was read by Dr. Granville S. Hanes of Louisville, Kentucky, on the Surgical Anatomy of the Colon. He pointed out that *in situ* the large intestine was shorter than after dissection, and that a 30-inch colon tube was long enough to extend from the anus to the cæcum; however, he claimed that it is not possible to pass a rectal tube beyond the middle of the sigmoid, and beyond this the splenic and hepatic flexures form insurmountable obstacles to the passage of a tube. He had been able to show that a bland liquid introduced by means of a funnel and tube into the rectum would flow out of an old appendicotomy opening after a few minutes. He insisted that the "inverted" position of Hanes was to be preferred both by the operator and the patient when any kind of illuminating instrument is to be employed in the rectum or sigmoid. A "symposium" on Constipation, embracing seven different parts of the subject, was presented: Dr. Horace Heath of Denver spoke on the Etiology of Constipation; Dr. Samuel T. Earle of Baltimore on its Physiology; Dr. John L. Jelks of Memphis on the Bacteriology of, and the Urinary Findings in, cases of Constipation; Dr. W. M. Beach on the Pathology and Diagnosis; Dr. Alfred J. Zobel of San Francisco on the Sequelæ of Constipation, including Auto-intoxication; Dr. Dwight H. Murray of Syracuse, N.Y., on the Non-surgical Treatment; and Dr. Louis B. Hirschman of Detroit on the Surgical Treatment of Constipation. Dr. Donly C. Hawley of Burlington, Vermont, described two cases of pruritus ani which he had treated successfully by dilatation of the anal canal, scraping all ulcerated patches, and cauterisation of the entire area of inflamed skin by means of a Paquelin cautery. Dr. T. L. Hazzard of Pittsburg described four recent cases of foreign bodies in the rectum. In two of these cases in children the foreign body was a match which had been swallowed, in another case a 3-oz. oval medicine bottle had been introduced by the patient; and in the fourth case the foreign body was a beer-glass 2 inches wide and 3½ inches tall; this also had been put in by the patient. In all the cases the foreign body was removed, but the beer-glass broke while being withdrawn. We make no

attempt to refer to every paper read at the meeting, but the interesting and important character of some of the observations justify what would otherwise seem an unduly specialistic undertaking.

ENGLISH CENSUS, 1911: PRELIMINARY REPORT.[1]

WE received recently a copy of the Registrar-General's introductory report on the twelfth Census of the population of England and Wales, which was taken on April 3rd, 1911. This volume furnishes the means of measuring the growth of the population during the several intercensal periods since 1801, the year of the first English Census. The report is based, not on a tabulation of the "household schedules" at the Central Office, but on the summaries of population returned by the local registrars, who are responsible for the enumeration of the inhabitants in their respective areas. It gives simply the numbers and sexes of the people in the counties, and in the urban, rural, and other districts of England and Wales. In preparing the subsequent reports the contents of the schedules themselves will be scrutinised at Somerset House, and amended population statistics will be set forth in greater detail than in the present report, which is avowedly a preliminary one merely.

In accordance with precedent, the enumeration of the people has been carried out by means of household schedules, the enumerators working under the direction of the district registrars. There are in this country 2009 registration sub-districts, which for Census purposes were subdivided into 35,000 enumeration districts, for each of which an enumerator was appointed. Considerable changes have been made in the enumeration arrangements—the most important of which consists in the discontinuance of the use of enumeration books. At previous Censuses the contents of the schedules were copied by the enumerators into books, from which the results of the Census were tabulated—a laborious task of which general complaint was made. With the object, *inter alia*, of avoiding risk of error in the process of transcription, the present Census Commissioners decided to relieve the enumerators of this complicated and monotonous work.

The present volume is merely introductory to the revised official returns of the recent Census. We learn that the first of the subsequent volumes will consist of information relating to the whole country, but dealing with particular subjects only. At a later date volumes will be issued relating to separate counties or groups of counties. Finally, a report will be presented on the "Census of the British Empire," somewhat on the lines of the Census Report of 1901, which for the first time afforded authoritative statistics for the Empire as a whole.

Census Results.

The returns show that at midnight on Sunday, April 2nd, 1911, there were living in England and Wales 36,075,269 persons at all ages and of both sexes, or an increase of 10·9 per cent. on the numbers enumerated in April, 1901. In proportion to population, the percentage increase was smaller, although the actual increase of population since last Census was numerically greater than in any previous decennium. The net gain of population, by excess of births over deaths, which had been 12·39 per cent. in the intercensal period immediately preceding, rose in the period 1901–1911 to 12·44 per cent., this result being due to the counterbalancing of the great reduction of the birth-rate by a still greater reduction of the death-rate.

Sex Proportions

Of the 36,075,269 persons enumerated at the last Census, 17,448,476 were males and 18,626,793 were females. This gives an excess of 1,178,317 females over males. The proportion of females to males was the same at the two last Censuses—viz., 1068 to 1000—but when allowance is made for the number of men absent on service in South Africa in 1901 there is no doubt that the true proportion of females to males was somewhat lower in 1901 than in 1911. The sex distribution of the population varies considerably in different parts of the country; for whilst the proportion of females to 1000 males did not exceed 912 in the county of Monmouth it was equal to 1218 in Sussex.

Population Estimates.

The provisional estimate of the English population in 1911, based on the assumption of an annual rate of increase equal to the mean rate in the previous intercensal period, was in excess of the enumerated Census population by 1·13 per cent. In 1901 the estimated was less than the enumerated population by 0·44 per cent. Rates of mortality and other expressions showing proportions to the estimated population are necessarily affected to a corresponding extent, but, of course, in the opposite direction. Thus the birth-rate and death-rate for the year 1910, provisionally given in the Annual Summary as 24·8 and 13·4 per 1000, are found, on revision, to be 25·1 and 13·5 respectively. Taking England and Wales as a whole, the errors arising from the traditional method of estimating populations will be seen by the above figures to be comparatively trivial, but in calculating the mortality-rates for certain local areas where the differences between estimated and Census results are far greater, the defect of any method based on a general assumption is very serious. Moreover, it is in these very cases that the difficulty of devising a remedy is greatest. The natural increase of the population by excess of births over deaths is known; but the balance of inward and outward passenger movement (the balance of migration) is not known. If only trustworthy statistics of passenger movement classified according to place of residence of the passengers were available, it would become possible to frame current estimates of the English population which would be approximately accurate from year to year. It is earnestly to be hoped that in the near future this necessary information may be forthcoming. But the method of estimating population by births, deaths, and migration is now only practicable in the case of England and Wales as a whole; it is not possible in the case of portions of the country, since no records of internal migration exist. Perhaps the most promising of the many methods hitherto suggested for overcoming this difficulty is that which has been adopted in the case of the metropolitan boroughs, where estimates based on the rate-book records have been made for several years past under the Equalisation of Rates Act. There is reason to believe that in the course of those years the accuracy of the estimates has been generally increased. In a few instances, however, notably those of Wandsworth, Westminster, Finsbury, Lewisham, Woolwich, and Greenwich, the method has hitherto failed. These instances serve to show that, in the words of the report, "even the best methods hitherto devised for estimating populations of local areas cannot be trusted in the later years of a decennium. They therefore emphasise the importance of more frequent Census enumerations, not only in the interest of vital statistics and sanitary progress, but also for the purpose of ensuring the proper distribution of public funds when this is to be determined by the number of the population."

Administrative County of London—Greater London.

In the 100 years 1801–1901 the population of the area now covered by the Administrative County of London increased from 959,310 to 4,536,267. At the Census of 1911 the population was found to number only 4,522,961, showing for the first time an actual decrease of 0·3 per cent. In recent previous decennia the increase has varied from 7·3 to as much as 17·4 per cent. The metropolis furnishes the most remarkable instance of decline of population in the central portion of a large city. In the centre of London the population has for many years been decreasing owing to the substitution of business premises for dwelling houses. But around this central area there is a circle of districts the population of which is gradually increasing; whilst outside these again there is a zone of suburban districts in which the population is increasing with extraordinary rapidity. Outside the Administrative County is a wide belt of suburban towns and districts designated the "Outer Ring," which, together with the County of London, constitutes "Greater London." The population of this area now exceeds seven and a quarter millions; and although its growth in the recent decennium has been less than in previous decennia, it amounted to more

[1] Census, 1911: Preliminary Report. [Cd 5705.] London: Wymans, Limited. Pp. 142. Price 1s. 4d.

than 670,000 persons, or 10·2 per cent. In the "Outer Ring" the increase was equal to 33 per cent.

United Kingdom.

The total number of persons returned as living in the United Kingdom on April 3rd last was 45,216,665, an increase of 9·1 per cent. on the number enumerated ten years previously. The population of England is returned as 34,043,076, that of Wales 2,032,193, that of Scotland 4,759,445, and that of Ireland 4,381,951. While the populations of England, Wales, and Scotland have shown continuous increases during the last 90 years, the population of Ireland, which in 1841 had risen to over 8,000,000, has shown a continuous decrease ever since that date. England now contains 75 per cent. of the population of the United Kingdom, Scotland rather more and Ireland rather less than 10 per cent., whilst Wales contains the remaining 4½ per cent. In the early part of last century Ireland contained nearly one-third of the population of the United Kingdom, but at the recent Census it was only 9·7 per cent.

THE SIXTY-FIFTH REPORT OF THE COMMISSIONERS IN LUNACY.

Numbers of Insane in England and Wales.

ON Jan. 1st, 1911, the number of certified insane persons in England and Wales was 133,157, exceeding the number recorded on Jan. 1st, 1910, by 2604. The average annual increase for the ten years ending Dec. 31st, 1910, was 2521, and that for the five years ending on the same date 2236. The increase for the year 1910 was therefore 83 above that of the annual average of the decennium and 368 above that for the quinquennial period. The increase in the population of the county and borough asylums for the year 1910 amounted to 2·2 per cent. The number of patients in registered hospitals increased by 3·3 per cent., in the criminal asylums by 4·3 per cent., in ordinary workhouses by 2·3 per cent., and in the metropolitan district asylums by 2·9 per cent. The private single patients have increased by 3 per cent., whilst the decrease in the number of insane outdoor paupers amounted to 3·2 per cent., and of patients in licensed houses to 1·6 per cent. in the metropolitan and 1·1 per cent. in the provincial houses. Private patients under care on Jan. 1st, 1911, numbered 10,890 (males 4709, females 6181), an increase on the figures of the preceding year of 274, or 2·5 per cent. A fact of some interest has been the change that has taken place in the relative distribution of the sexes since reliable statistics were established. Thus in 1859 the class of private patients comprised 2456 males and 2223 females, or a percentage distribution of males of 52·5, females 47·5; whereas in 1911 the proportions are reversed, being males 43·2 and females 56·8.

The pauper patients under care on Jan. 1st, 1911, were 121,172 (males 56,142, females 65,030), amounting to 91 per cent. of all the notified insane. The numbers show an increase of 2271 over last year, a figure which is 24 below the mean annual increase of the past ten years, but as many as 747 above that of 1909. The rate of increase of last year's numbers was 1·9 per cent., or 0·6 below that of the private patients. The males increased by 1·8 per cent. and the females by 1·9. In this class the female sex has always markedly predominated as evidenced by the percentage proportions. The criminal insane (males 832, females 263) show a net increase of 59, of which 22 appertain to the county and borough asylums.

Ratios of Insane to Population.

On Jan. 1st, 1859, there were known to be under care 36,762 persons certified as insane, and on Jan. 1st, 1911, the number so notified amounted to 133,157, an increase on the numbers of 1859 of 262·2 per cent. During the same period the estimated population of England and Wales has increased by 85·8 per cent. A clearer estimate of the apparent disproportionate growth of the numbers of the insane is to be found by contrasting at different periods the ratio which the latter bear to the general population. On Jan. 1st, 1911, the total number of notified insane persons stood to the estimated population in the proportion of 1 to 275, or 36·4 per 10,000. This gives an increase on the ratio of the preceding year of 0·83 per cent. On Jan. 1st, 1901, this ratio was 33 09, so that in the ten years it has increased by 10 per cent., the proportion of insane to the population rising from 1 to 302 to 1 to 275. The ratio of insane to population, which on Jan. 1st, 1869, was 23·93 per 10,000, had risen to 36 40 on Jan. 1st, 1911, an increase of 52 1 per cent. The ratio of admissions to population, which in 1869 was 4·71, was 6 04 in 1910, an increase of 28·2 per cent., or 1·1 less than in 1909.

Is "Occurring" Insanity Increasing?

The Commissioners point out that the increase in the number of the insane recorded year by year is no proof of the growth of insanity in the community, although it is often assumed to be such. There are, in point of fact, no sufficient data for a correct judgment on the latter head, and such evidence as there is tends to the conclusion that if insanity is increasing at all it is doing so very slowly and not proportionately to the increasing numbers of insane persons under care. For instance, some indication, it might be thought, would be given by the numbers who are admitted to care for the first time. Statistical information as to these first admissions is only available from 1898 onwards, and the ratio which their numbers bear to the population has been almost constant, that of 1910, however, being lower than in any other of the 13 years. Of some significance is the slight but obvious increase in the number of cases which are admitted for their first attack of insanity, but even here the relative increase of such cases does not necessarily imply an actual increase of insanity, for there are factors to be considered which render it impossible to determine whether the actual proportion of "occurring" insanity is really increasing in the community. It is probable that far more care is taken to segregate persons suffering from the minor forms of insanity than used to be the case, and it is certain that in the case of the aged numbers now go to swell the list of first attacks which formerly were not removed to asylums. But whether insanity be increasing or not, there is no question that the increasing numbers of those who have to be cared for are due to accumulation—that is, to the increase in chronic and irremediable insanity due to survival.

Recovery-rates and Death-rates.

The daily average number of certified patients was last year 105,580, the proportion in county and borough asylums being 93·3 per cent. The admissions numbered 21,861, or 97 above the number in 1909; and of the total admitted 17,961, or 82·1 per cent., were first admissions, being 0·3 below the decennial mean. There were discharged 9824 patients, of whom 7501 were stated to have recovered. The recovery rate, reckoned upon the total admissions, was 34·31 per cent., being 1·67 below the rate for 1909, and 2·18 below the average for the ten years 1901–10 inclusive. The rate for females, 37·41, was higher than that for males, 30·84. The rate in the asylums was 34 per cent.; amongst private single patients 58 per cent. The deaths numbered 9777 and were fewer by 361 than in 1909. The death-rate reckoned on the daily average number resident was 9 26 per cent., being the lowest yet recorded in any year and 0·61 below the average for the ten years.

Factors in the Causation of Insanity.

The statistics before the Commissioners have, since their introduction upwards of 30 years ago, appeared to show that there is a family history of insanity in persons admitted to asylum care amounting on an average in the case of males to 19 per cent. and of females to 23 per cent. of the total yearly admissions. This is probably an under-estimate, as there is always a considerable number of patients concerning whom it is impossible to obtain positive information on the point. The Commissioners point out that the question is not simply one of an *insane* heritage, but rather of a transmission of an instability of the nervous system which may manifest itself in many directions apart from actual insanity. Besides insane heredity two other factors stand out prominently in the history of insane persons. These are the toxic agent alcohol and the factor of mental stress. As regards alcohol, it was returned apart from any correlated factor in 7·3 per cent. cases. Of the two main forms of mental distress, that which is prolonged is far more commonly associated with the development of insanity than are sudden emotions and shocks. It appears from the returns to have been the only assignable cause in 9·6 per cent. cases, while sudden stress was thus

accepted in 2·2 per cent., each form being rather more frequently thus observed in females than in males.

With regard to the Asylum Officers' Superannuation Act, 1909, the Commissioners regard it as too early to speak with confidence as to how the Act is working generally, while it will take some time before all the points of difficulty that may arise will be satisfactorily cleared up. They welcome the Act as a move in the right direction, and hope that if some of its provisions turn out to be so restrictive as to be unworkable steps will be taken to get them amended.

REPORT OF THE MASSACHUSETTS STATE BOARD OF HEALTH FOR 1909.

THERE is little need at the present time to emphasise the necessity for a pure water-supply in order to maintain a high standard of public health; and, as a matter of fact, in the last report of the medical officer to the Local Government Board not a single epidemic due to water-borne disease is related to have occurred, so satisfactory is the condition of things in this country in this respect; nor was any inquiry deemed necessary in regard to any town of importance as to the sufficiency or purity of its sources of drinking water-supply. A similar satisfactory state of things obtains in Massachusetts, where it is many years since any serious epidemic traceable to a public water-supply has been recorded, a result doubtless due, in a very considerable degree, to enforcement of legislation for the protection of such supplies. Moreover, the improvement in health of the population has been far more marked than can be directly attributable to diminution in water-borne disease. Statistics of sickness are not available, but the reduction in the general death-rate has been greatly in excess of that due to enteric fever or other diseases known to be spread by means of drinking water. This improvement in the public health has given to that State "a reputation for the protection of the public interests in this regard that has doubtless been of material advantage to it in other ways." We quote from the forty-first report of the State Board of Health,[1] and are glad to feel assured that the same might be said of the great majority of public authorities in our own country. As population increases danger may arise from tracts of land that are within the gathering ground of a public water-supply becoming inhabited; this has actually occurred in Massachusetts, and its possibility cannot be disregarded anywhere. No doubt an ample reservation has been secured around the artificial lakes that have within recent years been connected with Liverpool, Manchester, and Birmingham as water-supplies; and Loch Katrine, that supplies Glasgow, has so large a cubic content as to be practically safe if ordinary care be taken. The pollution of rivers in Massachusetts is a standing menace to public health, and in a much greater degree than with ourselves; contamination by sewage and foul drainage from manufacturing establishments has increased greatly during the past few years, and numerous complaints of nuisances have been made. All plans of proposed schemes of drainage are submitted to the Board of Health before being carried out; but it has no power to prevent or limit pollution of rivers by those places which had sewerage systems in existence before the laws requiring the approval of the Board were enacted; the Board has no power of action in such cases of continued pollution except to report to the legislature.

The working of the Lawrence Experimental Station has been continued with results of ever-increasing value. The sand filters, to which sewage has been applied for a period of nearly 22 years, continue to produce effluents purified as well as, or better than, ever; contact filters which have been used for eight years, and sprinkling filters in use for ten years, are still in operation; the purification of manufacturing wastes has been studied, and the disposal of sewage sludge by destructive distillation has been specially investigated. Some of the chief results of these researches will now be summarised.

Water Supplies.

The consideration of the quality of water-supplies, as determined by chemical examination, is divided into that of the surface waters and that of the ground waters, since these present essential differences in character. Averages of all the analyses made during the last five years have been calculated and the considerable body of information so obtained is presented in the form of tables.

Surface water-supplies.—The Massachusetts observers consider that the quantity of organic matter present in surface water is best indicated by the determination of the ammonia present, especially the albuminoid ammonia. They do not lay down any limit or standard, but present a large body of actual observations, carried out during five years on 146 different supplies. Taking 0·01 per 100,000 as a provisional standard (although this is not definitely recommended), we find that 21 out of 28 streams do not exceed this limit; but only 3 out of 48 lakes, and 10 out of 70 artificial storage reservoirs, are equally pure in regard to this index of organic matter. Of the streams, one only contained more than 0·02, while 5 of the lakes and 29 of the storage reservoirs exceeded this quantity. The running streams were, therefore, purer in regard to their organic matter than either lakes or reservoirs. It is stated that nearly all of these last were formed by the flooding of areas from which the soil and organic matters had not been removed. As to free ammonia, all of the streams except 1, all of the lakes but 5, and 50 out of the 70 storage reservoirs, contained not more than 0·005 per 100,000.

Ground waters.—There are fewer ground-water supplies; most of the older waterworks are supplied from surface sources, the new supplies are generally obtained from underground. The usual method of obtaining "ground water" is by tubular wells, sunk from 25 to 50 feet deep; next in frequency come large circular wells, 20 to 40 feet deep; then the so-called filter galleries, which are "elongated wells," 10 to 20 feet deep, located along the shore of a pond or near a stream. These galleries are usually rectangular in section and often several hundred feet long. Both the shallow circular wells and the filter galleries are often supplemented by tubular wells sunk in their bottoms or near by. The most important consideration in comparing the qualities of ground waters is their relative freedom from sewage pollution; this is ascertained by determining the normal quantity of chlorine present, then by examination finding the total quantity in the sample; the excess is presumably due to sewage impurity. The waters are divided into three groups: those in which the excess of chlorine is *nil*, or not more than 0·1 per 100,000; those in which it is between 0·1 and 0·3; and those in which it is more than 0·3. Of a total number of 88 ground-water sources, 40 came under the first head, 20 under the second, and 28 under the third. The amount of nitrate present is also regarded as an index of exposure to pollution in a ground water. When this is derived from uninhabited ground the nitrates are either absent or very scanty; they are present slightly in waters derived from pasture lands, in noticeably larger quantity in waters derived from cultivated lands, and are very high in those from thickly settled regions, being formed from the ammonia of house drainage and other animal matter. Their determination therefore is of value, especially in connexion with the chlorine analysis. In 30 cases the nitrates were less than 0 01 per 100,000; in 45 between 0·01 and 0·1; and in 15 they exceeded 0·1. Of the 30 waters that were pure as regards nitrates, 24 also contained only 0·1 or less of excess chlorine; of the 15 waters containing more than 0 1 nitrates, 14 also contained more than 0·3 excess of chlorine. The determinations of the free and albuminoid ammonias in ground waters are "indices of the extent to which a polluted water has been purified and freed from organic matter in its passage through the ground." In only four of the 90 samples was more than 0·01 per 100,000 detected of albuminoid ammonia; three out of these four were in the first class as regards freedom from chlorine, and the same three contained less than 0·02 nitrates. In only five out of the 90 was more than 0·01 free ammonia found; three of these also contained more than 0·01 albuminoid ammonia, two of which were in the first class as regards chlorine. Purity, reckoned from minimal chlorine content, may therefore coexist with relatively high ammonia content, both free and albuminoid. No allusion is made to the bacterial content of these waters. It does not appear that the chemical constitution, however carefully determined, can afford any indication of the safety or otherwise of a drinking water comparable in value with that to be obtained from bacteriological

[1] Forty-first Annual Report of the State Board of Health of Massachusetts. Boston, 1910.

examination, though the one form of examination may usefully check the other.

Consumption of water.—In the metropolitan water district, comprising Boston and its neighbouring towns, with a population of just over a million, the consumption is 121 gallons (U.S.) daily per head (= 101 imperial gallons); a few towns have an even larger supply. Boston itself has 119 imperial gallons per head; in nine only is it less than 25 imperial gallons per head per day.

Purification of Sewage.

The world-renowned experiments at the Lawrence Station are still being carried on; the sand-filters have now been in operation for 22 years, and trickling filters and contact beds for ten and eight years respectively. Mr. H. W. Clark and Mr. S. Gage, who contribute this report, state that "sludge disposal is at present the most serious problem in the disposal of sewage on a large scale, and, as in past years, methods of disposing of sludge, and also the sediment present in the effluents of contact and trickling filters, have received attention."

Preliminary treatment for clarification.—Experiments have been continued on the action of the settling tank at Lawrence. This is a cylindrical tank with a sloping bottom; the sewage enters near the bottom and rises slowly to an outlet near the top, the period of sedimentation being about two hours; the sludge is removed each week.

Parts per 100,000.	Albuminoid ammonia.		Kjeldahl nitrogen.		Oxygen consumed.	Bacteria per c.c.
	Total.	In solution.	Total.	In solution.		
Lawrence sewage	0·91	0·52	2·75	1·83	9·52	1,136,400
Settled sewage ...	0·48	0·28	0·88	0·50	3·85	977,800

The average removal of suspended matter from the sewage during the year has been about 41 per cent., as shown by the albuminoid ammonia results; the total removal of organic matter has been 29 per cent. and 32 per cent., as shown by the total albuminoid ammonia and oxygen consumed respectively. A similar settling tank at Andover has furnished similar results. A third tank has been installed on the Imhoff, or Emscher, principle. This is of cylindrical form with conical bottom, inside which is a smaller cylinder of similar shape, containing a baffle plate, and provided with a trapped outlet connecting it with the large tank in which it is suspended. The sewage enters at one side of the inner tank, flows under the baffle plate, then rises and overflows through an outlet on the other side. The solids deposited in the inner tank pass downward through the trapped outlet into the large tank, where they accumulate and become decomposed by bacterial action. Owing to the trap in the outlet of the inner tank, the gases and other products of sludge decomposition do not mingle with the sewage during its passage through the tank. The capacity of the outer tank is equal to about 24 hours flow, and that of the inner tank to about five hours flow. During five months' working 86 per cent. of suspended matters was removed, as shown by albuminoid ammonia; and 71 per cent. of total organic matter, as shown by both albuminoid ammonia and oxygen consumed. The sludge accumulated in the five months amounted to about 25 cubic feet per million gallons of sewage. The efficient removal of suspended matter is said to be largely due to the fresh character of the sewage.

Parts per 100,000.	Albuminoid ammonia.		Kjeldahl nitrogen.		Oxygen consumed.	Bacteria per c.c.
	Total.	In solution.	Total.	In solution.		
Fresh sewage ...	1·89	0·72	5·63	3·04	10 00	2,849,300
Imhoff tank effluent	0·55	0·38	1 38	0·99	2·87	2,704,100

Filtration.—The working of the historic sand filters at Lawrence has been continued, four filters having now been in operation for nearly 22 years. For 16 years (since 1893) these filters have been operated without removal of the sand, the surface being merely dug over four times a year. In winter the trenches are covered with boards, which, together with the snow that accumulates on them, protect the filters from cold. Filter No. 1 may be taken as an example; it is 60 inches in depth and has had sewage applied at the rate of 50,000 gallons per acre; the size of the sand particles is 0·48 millimetre.

Parts per 100,000.	Free ammonia.	Albuminoid ammonia.	Oxygen consumed.	Bacteria per c.c.
Sewage...	4·06	0·67	5·43	—
Filter effluent ...	0·7688	0·0626	0·72	7600

Four "contact filters" are described; two of these, 5 feet in depth and composed of coke fragments, ¼ to 1 inch in size, have been in use since 1901; they are each filled once daily, and allowed to stand full for two hours. No. 175 was operated at an average rate of 415,500 gallons, and No. 176 at 270,000 gallons per acre daily, the former receiving sewage that had passed through a coke or coal strainer, the latter settled sewage. The former worked well, yielding an effluent containing 0·8698 free ammonia and 0·2670 total albuminoid ammonia, and 2·07 oxygen consumed; the latter lost about 11 per cent. of its open space during the year, and became badly clogged with organic matter. The effluent averaged 1·1545 free ammonia, 0·1644 total albuminoid ammonia, and 1·64 oxygen consumed. Two "slate filters" have been under observation; it is stated that filters constructed of horizontal layers of slate "were first tried at this station in 1901, and they have been much exploited in England during the last few years." The two at Lawrence are constructed of layers of roofing slate placed horizontally, the layers of slate being separated from one another by small concrete blocks ¾ in. thick. One (No. 376) contains 27 layers of slate, the exposed surface available for sludge deposition being about 314 square inches per gallon of sewage when full; the other (No. 377) has eight layers, and about 187 square inches of surface per gallon of sewage. Both are operated as "contact filters," being filled in one dose daily, and drained slowly after a two hours contact; they have been operated six days a week for five months without any sludge removal. No. 376 has received ordinary sewage, and No 377 fresh supernatant sewage from the Imhoff tank. The purification has been as follows:—

Parts per 100,000.	Free ammonia.	Total albuminoid ammonia.	Oxygen consumed.	Bacteria per c.c.
No. 376, Sewage	2·63	0 420	3·25	—
Filter effluent ...	2·36	0·314	2·25	516,300
No. 377, Sewage	6·25	0·69	4·46	—
Filter effluent ...	6·34	0·67	4·05	1,793,800

The nitrates in No. 376 effluent were 0·05 and in No. 377 were 0·13 per 100,000. There was practically no nitrification; "these so-called filters are simply contrivances to remove and, if possible, destroy sludge by biological action." This is the view generally held in this country, where they have been found to be effective and economical in dealing with the solid matters, but are not looked on as "filters," or as effective for complete purification of sewage.

Seven "trickling filters" have been in operation. The difficult question of effective distribution has been studied by a comparison between an automatic flush tank and dash-plates and a travelling distributer of the Fiddian type. The sewage flows into a hopper carried upon the central pivot, and thence through a central trough which travels with the distributer, and empties through a number of openings into the buckets upon the periphery of the cylinder; from these it is discharged upon the surface of the filter as the cylinder turns. Perfectly even distribution should, theoretically, result; in practice, small irregularities in the metal work of the apparatus, and slight unevenness in the track, the elimination of which would make the construction of the apparatus too expensive, have prevented

absolute uniformity of distribution. This, however, has been "much more uniform than with any of the devices previously tried." With the dash-plate method formerly in use only about 17 per cent. of the filter surface received the sewage at the intended rate—viz., from 1,000,000 to 2,000,000 gallons per acre daily; about 24 per cent. received none; about 23 per cent. received half the intended quantity; while 20 per cent. were flooded with 2,000,000 to 4,000,000 gallons, and 16 per cent. with 4,000,000 to 7,500,000 gallons. With the Fiddian system, about half the area received the intended rate, about a quarter 250,000 to 1,000,000 gallons, and the remaining quarter 2,000,000 to 2,500,000 gallons per acre daily.

Another difficulty in the management of filters results from clogging. Early in May some pooling was observed on one of the filters, and it was found that the surface layers were partly clogged with organic matter, but largely by the larvæ of a small fly (Psychoda alternata), whose presence had been noted in previous reports. These larvæ collect in the upper layers, cause the sewage to pool on the surface, and so cut off the ventilation; the flies themselves also die on the surface in large numbers. Copper sulphate was added to the sewage (830 lb. per million gallons) on four occasions, and at another time bleaching powder in the same proportion; the former had the best effect, but neither was quite satisfactory, and it was found necessary to dig over the top three or four inches of the filter surface in May and again in September to allow the sewage to pass. At the beginning of October the fly nuisance had practically ceased, but the filters were still badly clogged. Caustic soda (1000 lb. per acre) was then scattered over the surface; this broke up the clogging material, and the effluent was found to be heavily charged with organic matter. Notwithstanding the difficulty of keeping the surface of the filter open, the effluent during the summer was more highly nitrified and of better quality generally than in any summer previously. This the observers consider can only have been due to the more even distribution effected by the rotary distributer, with a resulting equalisation of work in the different parts of the bed; the increase in nitrates during May and June immediately following its installation was especially marked. Contrary to some observations that have been made in this country (e.g., those of Dr. George Reid at Hanley), progressive increase in nitrification was found to occur with increase in depth of filtering material; thus in filter No. 361, to which settled sewage was applied at the rate of 1,500,000 gallons per acre, the effluent at 2 feet depth contained 0·31 per 100,000 nitrogen as nitrates; at 4 feet, 0·71; at 6 feet, 0·96; and at the outlet, 8 feet 9 inches, 1·03. The oxygen consumed varied but little, being 3·16 at 2 feet; 3·41 at 4 feet and at the outlet; and 3·81 at 6 feet. Neither did the albuminoid ammonia vary much: at 2 feet it was 0·5186; at 4 feet, 0·5536; at 6 feet, 0·6517; and at the outlet, 0·4706.

Removal of bacteria.—The purifying power of the various types of filter was measured by determining the average numbers of bacteria developing on agar (1) when incubated four days at 20° C.; (2) when incubated 18 hours at 40° C. on litmus lactose agar; and (3) the number of red colonies on litmus lactose agar at 40° C. All the intermittent sand filters showed a removal of over 99 per cent. of all types of bacteria. Of the four contact filters, one which was badly clogged, and in which nitrification was feeble, showed a bacterial purification of 86 per cent.; while its companion, which was in good condition, removed only 0·8 per cent. of the 20° C. bacteria, and only 30·7 per cent. of the total bacteria growing at 40° C. Of the two slate filters (or rather slate beds), the one operated with ordinary sewage removed 60 to 70 per cent. of 20° C. and 40° C. germs, while the one operated with settled fresh sewage showed a removal of about one-third of the total, but none of the 40° C. bacteria. The older trickling filters, of ¼ to 1 inch material, were much more efficient than the newer ones with larger material, 1 inch and upwards.

Bacterial Purification of Water.

A new sand filter has been brought into operation at Lawrence 4½ feet in depth, the size of the grains averaging 0·25 millimetre; this has been worked at the rate of 3,000,000 gallons per acre daily. The Merrimac river water averaged 7400 bacteria per cubic centimetre during 1909, and the filter yielded water containing 100 per cubic centimetre. The old filter, constructed in 1893, having a depth of 4 feet, has been worked at an average rate of 1,250,000 gallons daily; the applied water averaged 7400, and the filtered water 60, bacteria per cubic centimetre. Thus the old filter, operated at a lower rate, gave a bacterial efficiency of 99·2, compared with 98·7 per cent. of the new one. The bacillus coli efficiency of the old filter (presence in 8·6 per cent. of 1 cubic centimetre samples) was much higher than that of the new one (presence in 17·1 per cent. of 1 cubic centimetre samples); the raw water contained bacillus coli in 100 per cent. of 1 cubic centimetre samples.

Purification by the addition of chemicals has been studied in relation to potassium permanganate and calcium hypochlorites. With the former 98 per cent. of the bacteria were eliminated by treatment with 0·5 per 100,000 for four to six hours; larger amounts and longer duration did not appreciably increase the effect. The addition of calcium hypochlorite, equal to 0·1 per 100,000 of available chlorine, for one to two hours, caused a reduction of 99 per cent., and "resulted in an effluent corresponding in bacterial quality with the effluents from the best slow sand filters." In the case of both chemical agents the reduction in number of bacteria growing at the body temperature was less than that of common water bacteria; in 20 to 25 per cent. of the samples treated with hypochlorite the counts at body temperature were actually higher than those at room temperature. This phenomenon of "reversed counts" occurs in a considerable proportion of cases in which the room temperature counts have been reduced below 200 per cubic centimetre by the use of hypochlorites, permanganates, or other oxidisers; but not in samples containing large numbers of bacteria, nor in those where the numbers have been reduced by copper sulphate or other non-oxidising disinfectants. Spore-formers are found in practically the same proportion after, as before, disinfection; but the true significance of the phenomenon cannot at present be stated. It is evident, however, that reliance must not be placed entirely on room temperature counts in estimating the purification effected by hypochlorites. Moreover, in waters so purified a large increase in total bacteria takes place on storage, varying from 100 to 7500 per cent. and averaging 670 per cent.

Among other subjects dealt with in the report are the anaerobic bacteria in milk and the prevalence of infantile paralysis; an inquiry into this disease is still proceeding. The present volume fully maintains the high standard of thoroughness and accuracy that has always characterised the series, and is equal to any of its predecessors in interest.

PLAGUE IN THE NEAR EAST.

(FROM THE BRITISH DELEGATE TO THE CONSTANTINOPLE BOARD OF HEALTH.)

Plague in Odessa.

SINCE the date of my last letter on this subject (published in THE LANCET of June 3rd, p. 1528) the plague infection has reappeared in Odessa, where, it will be recalled, it caused an epidemic of some severity last year. On June 6th (19th) an inhabitant of the town, a woman employed in business, was declared to be suffering from the disease, as shown by the result of a bacteriological examination. Three days later a second case was declared; the patient, a child, occupied the same house as the first case. On July 16th (29th) 3 further cases were seen; 2 of these occurred in the crew of the s.s. *Veronezh*, of the Russian Volunteer Fleet, and the third was an inhabitant of the Moldavanka quarter of the town; one of the former died. The steamer remained in the port for a month and then sailed for the Far East. Finally, a telegram from the Russian Ministry for Foreign Affairs, dated July 21st (August 3rd), states that in the preceding week 5 cases of plague had been recorded in Odessa, with 2 deaths. Presumably these 5 cases include the 3 just mentioned, the details of which are quoted from the Russian medical papers. No further cases occurred in the following week.

Plague in the Kirghiz Steppes.

These now well-known centres of endemic plague are still more or less active. In the *urotchistché* of Uzbek, in the 9th district of the maritime province of the Kirghiz steppes, 4 fatal cases of the pneumonic form of the disease occurred in a single family between June 5th and 23rd (June 18th and July 6th). The infected earth-huts (*zemlianki*) were burnt

and the inhabitants of the settlement, 98 in number, were kept under medical observation for a suitable period. At a date not named, but apparently some time in July, 7 Kirghiz were attacked with plague, and all died, in the *urotohistohé* of Kosum. Kosum is said to be situated in the 1st circle of the Kirghiz Horde, on the frontiers of the Uralsk Province.

From other sources it is learnt that outbreaks of plague occurred in May and June at Oujaly and Saralfyn, in the Narynsk district. In the former, 4 fatal cases—all members of one family—were seen between May 7th (20th) and 27th (June 9th). In the latter, which is 12 versts from Oujaly, 3 Kirghiz, members of one family, fell ill of plague between May 26th and 31st (June 8th and 13th), and all died.

For some time past a medical commission, under the leadership of Professor Metchnikoff, and consisting of Dr. Salimbeni, Dr. Burnet, and Dr. Jamanuchi (the last named from Japan), has been investigating the disease as it manifests itself in the Kirghiz steppes. Their report is said to have been recently completed, though apparently it has not yet been published. From a reference to it in a recent number of the *Vratch*, it appears that the marmot, known in Russian as the *bobak* or *tarbagan*, does not occur in the Kirghiz steppes. It is replaced there by a similar rodent, known in Russian as the *suslik*, which would seem to be also a kind of marmot, though presumably of a different species from the other. In the neighbourhood of Kosai, in the steppes, where plague was epidemic last December (see my letter in THE LANCET of Feb 25th last, p. 534), large numbers of the runs of these animals were found close to the spot where those who had died from plague had been buried. But in no instance were plague bacilli found in the animals, though these were shown to be exceedingly susceptible to plague artificially inoculated. The *susliks* were also found not to harbour fleas; but a small tick (*klestch*) was common enough, occurring particularly behind the ears of the animals. Some of the members of the commission, who still remain in the steppes, are pursuing their investigations into the relation of these animals and their parasites to the spread of plague. Incidentally it is mentioned that investigations were also made into the presence of tuberculous disease in these regions. In 50 per cent. of some 3000 instances in which the skin reaction was taken, the result is said to have been negative—which presumably implies that it was positive in the other 50 per cent. In some places, notably in the Kalmuck bazar near Astrakhan, as many as 75 to 95 per cent. gave positive reactions.

Plague in Adalia.

There has recently been a revival of sporadic plague at Adalia, on the southern shores of Asia Minor, where similar outbreaks have occurred annually for the last few years. The first case was seen on July 4th; the patient was a labourer in a mill; he died the same day. The next case was reported on July 17th; the patient was a sergeant-major in the army, living in the same quarter as the first case; he also died. On July 30th, a third case was reported; the patient was a Kurd, a municipal street-sweeper; he had been ill for two days, and was already dead on arriving at the hospital on the 30th. A fourth case followed on August 1st, and a fifth on the 2nd. All these cases were of the bubonic variety of the disease.

Plague in Muscat.

The following figures are in continuation of those published in my last letter:—

Week ending May 13th	.....	5	cases,	5	deaths.
,, ,, ,, 20th	.....	5	,,	5	,,
,, ,, ,, 27th	.....	3	,,	2	,,
,, ,, June 3rd	.....	0	,,	0	,,

Finally, Muscat was declared free of plague on June 15th.

Plague at Bushire.

Since the last figures were published the following returns have been received from Bushire:—

Week ending May 13th	.....	12	cases,	7	deaths.
,, ,, ,, 20th	.....	24	,,	23	,,
,, ,, ,, 27th	.....	17	,,	16	,,
,, ,, June 3rd	.....	16	,,	13	,,
,, ,, ,, 10th	.....	?	,,	?	,,
,, ,, ,, 17th	.....	9	,,	11	,,
,, ,, ,, 24th	.....	8	,,	?	,,
,, ,, July 1st	.....	0	,,	1	,,

Finally, Bushire was declared free of plague on July 5th.

Plague in Bahrein.

The outbreak of the disease in the Bahrein Islands recently took on a very severe character. It will be recalled that down to May 5th, 30 deaths from plague had occurred there. On May 18th it was reported that 175 cases had been seen down to the 14th of that month. On June 15th a telegram was received from Bushire stating that in the 15 days ending May 29th the mortality from plague in the islands was estimated at about 700 deaths, followed by about 600 others in the "13 days ending June 29th." There appears to have been an error in the transmission of this telegram, the last-named date being obviously wrong, as the telegram was dated June 15th. In the same telegram it was stated that plague was present on the Arabian shores of the Persian Gulf, known as the Trucial coast; that it had been severe at the beginning, but was then declining. A later telegram, dated June 29th, reported that about 300 deaths had occurred in Bahrein during the 15 days ending June 25th. Later telegrams show that there were 110 deaths there in the fortnight ending July 9th, and 10 deaths in the week ending July 16th. No subsequent deaths were reported, and on August 3rd the Bahrein Islands were declared plague-free.

Plague at Basra.

As already reported, 2 cases of plague occurred here on May 6th and 11th respectively. On May 14th a third case followed, the patient being a baker, living close to the other cases. About the same time it was reported from Basra that ships' captains arriving there from ports on the Trucial coast confirmed the existence of an epidemic of plague on that coast, of which mention was made above. No details of that epidemic have, however, as yet been received. On May 19th and 22nd 2 more cases occurred in the infected quarter of Basra, and another one on May 31st. There were 4 deaths in this small outbreak at Basra.

Constantinople, August 19th.

THE BRITISH DENTAL ASSOCIATION.

ANNUAL MEETING.

WE lately published[1] an account of the meeting in London of the Eleventh Annual Session of the International Dental Federation, which by gathering annually in various capitals arranges for the meetings every five years of the International Dental Congress. This year the delegates were the guests of the British Dental Association, which held its thirty-first annual meeting at the University of London on August 3rd, 4th, and 5th, with special receptions by the Royal College of Surgeons of England at its building, and at the Hotel Cecil and other places arranged for by the large and important metropolitan branch of the association.

As the new President of the association for 1911–12, Mr. W. B. Paterson, senior dental surgeon at St. Bartholomew's Hospital, also is the President of the International Dental Federation, it was but natural that distinguished representatives of the profession from abroad should linger in our metropolis and make common cause with British dentists in discussing many important questions regarding the education of our dental *confrères* and the part they can take in State provision for better oral conditions among the young, the poor, and the great national services.

Greatly appreciated by dental practitioners was the interest shown by the President of the Royal College of Surgeons of England, Sir Henry Butlin, and the Council of the College who placed at the disposal, not only of the International Federation, but also of the British Dental Association, the building of the College, with its unrivalled museum, so rich in odontological specimens. The coincidence of the international meeting with the annual meeting of the British body, and the fact that the President of the Federation was also President of the Association—having been during 21 years successively honorary secretary and chairman of the representative board—accounted for an annual meeting this year in London which was by far the largest ever held. With a total membership now of about 2020, there were in London at least 1000, including visitors and ladies; and as the association comprises a good majority of all medically qualified dentists, the annual deliberations of the body must necessarily command serious attention.

[1] THE LANCET, August 19th, p. 529.

Among the formal annual reports made to the meeting that of the representative board dealt at some length with such questions as the need of better and more precise legislation in the interests of both the public and the profession, as shown by the opinions of high judicial authorities, the revelations of the recent Blue-book on unqualified practice, and the well-known great increase of an amount of irregular and totally incompetent "dentistry" never contemplated by the promoters of the present Dentists Act or by Parliament when it was drafted; also the position of the profession in assisting with the examination and treatment of school children under recent enactments.

Dental Treatment of School Children.

Upon the latter important matter, in which the coöperation of dental and medical practitioners is acknowledged to be essential, the board report said:—

As a proof that the importance of dental treatment is recognised by the highest authorities, it is satisfactory to be able to point to the special chapter on the subject in the Second Annual Report of the Chief Medical Officer of the Board of Education, in which several recommendations of the association are adopted. An experimental clinic has been started by the London County Council in connexion with the Poplar Hospital, and a half-time dentist appointed; and at Deptford a clinic, which owes its inception to private munificence, receives L.C.C. school children. No system of dental treatment at any of the large general hospitals on the lines of the experimental scheme of medical treatment has been instituted, and as nearly all the dentists attached to such hospitals are of opinion that this method is inadvisable, it is unlikely that anything of the kind will be attempted. The views of the association on the best means to be adopted have been submitted to representatives of the L.C.C. by members of the committee appointed for the purpose. Assistance has also been given to the Medical Committee of the Wandsworth clinic in drawing up plans for the inclusion of dental treatment, and it is hoped that such treatment will before long be instituted. Similar assistance has been afforded to the dentists of Norwood in connexion with the medical clinic in that district, and has also been submitted for the consideration of the Mid-Kent Organisation Committee.

In the provinces dental clinics have been started at Bradford and Norwich, a whole-time dentist will shortly be appointed at Coventry, and other towns are in process of making arrangements; an interesting experiment is being tried in West Dorset, the first strictly rural district to attempt dental treatment, where an itinerant whole-time dentist has been appointed. It is to be hoped that more may be done in the near future to inculcate the principles of hygiene of the mouth and prevention of dental caries by the organisation of instruction to teachers in training colleges, the regular inclusion of dental hygiene in school teaching, and lectures to parents.

Upon this subject the President (Mr. Paterson) in his inaugural address said:—

Long before Mr. John Burns passed his Medical Inspection Act of 1907 this association had been engaged in the collection of statistics relative to the condition of the teeth of the children of the public elementary and primary schools in various parts of the kingdom; and I have reason to believe that the results of our investigation were not without their uses at the Local Government Board in the preliminary considerations preparatory to the passing of that very important Act—an Act which is already working a silent revolution throughout the country, and one which in the future will have very far-reaching and beneficial effects upon the public health. Sufficient medical inspection of school children's teeth has now been accomplished, and the need of dental treatment is clearly and unmistakably indicated. We know that go where you will throughout the kingdom the teeth of the children require to be saved.

On the subject of the public dental hygiene for schools, the question of the day is, Which is the simplest and best way of setting about the business? In England Cambridge abroad Germany and Sweden, point the way. The school dental clinic appears to be the simplest, best, and most economical means at command. Professor Jessen tells me that they have already established 120 school clinics in the leading cities and towns of Germany. We have, in our association, for long pressed forward the claims of the school clinic, and the only barrier to progress has been the difficulty of finding the money, but now that the State Insurance Bill has turned all men's thoughts towards the financial aspects of public health, we may hope soon to see that barrier removed.

Our honorary secretary, Mr. Norman Bennett, who takes a very keen interest in all dental matters which relate to public health, deserves a special word of recognition and thanks. He has had an active time since the Inspection Act came into force answering questions addressed to our association by various public bodies on the subject of school dentistry and dentists. My knowledge of his answers leads me to say that he has his finger on the pulse of the dental hygiene movement, and that our interests are quite safe in his hands. I am glad of this opportunity of paying my tribute of respect to my colleague's sagacity in such matters, as many of them, owing to his innate modesty, never come within your view.

Whilst doing what we can as an association to direct public attention to the question of dental hygiene at home, we have not neglected the opportunity presented by the Dresden Hygiene Exhibition of enlightening our brethren abroad on our doings. We have recently sent to the British Section of that important exhibition a small and simple yet useful exhibit of the dental outfit of a Poor-law school clinic, and also copies of the association's literature, charts, and case-books in connexion with the care of children's teeth. I am told by those who have seen the exhibition that if Dresden was always worth a visit for art and music, it is trebly so now that a health exhibition is included.

The Care of the Teeth in the Services.

A considerable part of the President's address was devoted to the position of dentists in the naval and military services. As the official representative of the Dental Association upon the Army Medical Council's Advisory Board, and thus speaking with authority and experience, he said:—

You may remember how the British Dental Association was hurriedly called upon to arrange a dental service for the troops in the South African war. This service was so successful that it was increased in numbers during the war and maintained for some years after the war in the home establishment. Throughout its existence I constantly read the records of its work and the good reports of commanding officers, principal medical officers, and the complimentary official reports of three successive directors-general of the Army Medical Department. We know the subsequent turn of events. How during the piping times of peace the service of contract dental surgeons was allowed to languish. How it was made to appear superfluous, and finally to cease. What would happen to our troops in war, or in training manœuvres lasting for, let us say, a period of not less than two months, with no other dietary than that provided in a war ration of "bully beef and biscuit"?

In the navy matters are slightly better. A few contract dental surgeons are employed at the chief naval bases. But the service offers no permanency, and is crippled by a Treasury with a tight purse. How differently has the question of army dentistry been dealt with in the United States of America. There dentistry has been placed upon a permanent footing in connexion with the Army Medical Corps. By the new Act, dental surgeons now take rank as first lieutenants with pay and allowances accordingly. The regular pay is £400 a year with quarters, or in lieu of quarters £7 a month. There is longevity pay, amounting to a 10 per cent. increase on the regular pay, every five years for 20 years; and there is extra pay for foreign service of 10 per cent. on full pay.

Various Matters.

At the general meeting of members the principal subject of discussion was the action to be taken respecting the introduction of fresh legislation in amending the present law as to dental registration, practice, and the protection of title. Although a draft Bill has for some time occupied the attention of special committees, and had been remitted by referendum to the whole association, it was decided after a full discussion to again remit to the representative board the whole subject for further consultation and redrafting.

The retiring President, Mr. W. H. Waite of Liverpool (who was unfortunately not able to be present), was elected a Vice-President, and the following were elected honorary members: Dr. W. H. Williamson of Aberdeen, a former president; Mr. J. Dennant of Brighton, joint founder with Mr. Waite of the benevolent fund; Dr. G. V. Black of Chicago, who obtained the I. D. F. Miller prize; Professor O Walkhoff of Munich, president of the International Dental Congress in Berlin in 1909; Dr. E C. Kirk, Dean of the Faculty of Dentistry in the University of Pennsylvania and editor of the *Dental Cosmos;* and Professor E. Jessen of Strasburg, the pioneer of school clinics.

At the annual dinner at the Hotel Cecil on Thursday evening, among distinguished visitors were Sir Frederic W. Hewitt, Sir A. Pearce Gould, Sir R Havelock Charles, Professor Sidney H. C. Martin, Dr. Norman Moore, and many foreign guests. There were many provisions made for the entertainment of ladies by a committee presided over by Mrs. Paterson, which included a special ladies' dinner and a joint entertainment at the hotel after the banquets.

On Friday great interest was taken in papers on scientific and practical subjects (printed in advance and usually taken as read, so allowing of good discussion), and there were many demonstrations and exhibits in the halls of the University of London.

A feature of the meeting was a select museum, including orthodontic models, clinical cases, and specimens of students' work from American schools. A number of specimens from the museum of the Royal College of Surgeons of England on periodontal diseases were demonstrated.

The invitation of the Scottish Branch to hold the 1912 meeting in Glasgow at the University, on August 7th, 8th, 9th, and 10th, was cordially accepted.

ASYLUM REPORTS.

Nottingham City Asylum at Mapperly Hill (Annual Report for the Year 1910).—At this asylum the average number resident for the year was 818. In addition to the number resident at the end of the year 20 females were boarded out at the Storthes Hall Asylum. The admissions numbered 177 and were above the average as regards the males and below the average as regards the females. The character of the cases which were admitted was for the most part of an unfavourable type, having regard to the prospect of recovery, 6 being imbeciles, 23 general paralytics, 12 senile cases, 15 incurable dements, and 8 cases in which

insanity had lasted over 12 months when the patients were admitted. It would appear that alcohol was the cause of the illness in 25·4 per cent., mental stress and poverty in 23·6 per cent., hereditary predisposition in 14·8 per cent., old age in 7·1 per cent., and influenza in 4·1 per cent. of the admissions. Eighty-seven patients were discharged, and of these 72 were recovered, being 42·6 per cent. of the direct admissions. In 93 per cent. of the recoveries the duration of the illness before admission had been under three months. There were 78 deaths, being a percentage of 9·5 on the average number resident. Nineteen deaths were from general paralysis and 18 from phthisis. Post-mortem examinations were made in 93 per cent. of the deaths.

Staffordshire County Lunatic Asylum at Stafford (Annual Report for the Year 1910).—The daily average number resident was 874. At the end of the year there were no vacancies for women patients, and it appears that further accommodation will soon require to be provided. There were 241 admissions, and of these 11 men and 16 women had previously been under care. The discharges numbered 134, of whom 33 men and 31 women had recovered, giving a percentage of 31·68 of the cases admitted. There were 101 deaths, giving a percentage of 11·55 of the average number resident. Twenty patients died under three months' residence. Post-mortem examinations were held in 63 cases.

Staffordshire County Lunatic Asylum at Burntwood, near Lichfield (Annual Report for the Year 1910).—The number of patients received at this asylum, together with the low death-rate, has obliged its authorities to transfer some of the patients to the other asylums of the county, but, nevertheless, there are 26 patients in excess of the number for which the asylum provides statutory accommodation. The average daily number on the registers was 889. Admissions numbered 281. One hundred and fifty-seven persons were discharged during the year, and of these 71 were recovered. There were 84 deaths, giving a percentage of 7·31 of the total number under treatment.

Staffordshire County Lunatic Asylum at Cheddleton (Annual Report for the Year 1910).—The average daily number on the registers was 977. At the end of the year the female side of the asylum was full. There were admitted 269 cases, of whom 185 were already chronic. Among the non-recoverable cases there were 33 general paralytics, as against 20 admitted during the previous year. Eighty-three persons were discharged, and of these 57 were recovered. Deaths numbered 125, 32 being from tuberculosis, 13 from general paralysis, 15 from pneumonia, 15 from dysentery, 1 from enteric fever, and 37 from chronic degenerative disorders. Dr. W. F. Menzies, the medical superintendent, is of opinion that the type of dysentery obtaining at the asylum is acquiring increased virulence. A common predisposing cause has been observed to be sudden changes in temperature, for warm weather preceded by cold disposes to bacteriological changes in food-stuffs, while cold weather after warm tends to produce chills among the patients. The vogue of open windows, however advantageous to the general asylum population and to tuberculous cases in particular, is bad for dysenterics. It is certain that a large number of persons are carriers, and it will probably be some time before these are all discovered by bacteriological and clinical research. During the year all the dysenteric cases have been examined bacteriologically, and perhaps the outstanding result has been the variety of micro-organisms found. The Flexner bacillus proved to be the organism most commonly present. As regarding treatment, sera and vaccines have been used, but it is plainly too early to form a judgment of their value. Dr. Menzies is now treating the patients by draughts and enemata of potassium permanganate solution.

West Sussex County Asylum at Chichester (Annual Report for the Year ending 1910).—The average daily number on the registers was 763. There were 154 admissions. Of the females admitted 53·8 per cent. were regarded as possible or probable recoveries, while of the males admitted in 65·56 per cent. the chances of recovery were considered to be very remote. Of etiological factors heredity, so far as could be ascertained, was present in 39·74 per cent. of the cases. Sixty-three patients were discharged, of whom 42 were recovered, the rate on the direct admissions being 30·65 per cent. In nearly all the recoveries the duration of the attack on admission was less than six months. There were 80 deaths, and necropsies were held in all cases except two. The death-rate on the daily average number resident was 10·48 per cent. Seventeen deaths were due to tuberculous disease and 18 to general paralysis.

THE TREATMENT OF WOUNDED SOLDIERS IN TIME OF INVASION.

WE have received from a correspondent at the recent manœuvres of the 2nd London Division of the Territorial Force at Shorncliffe the following interesting and instructive account of the working of the medical arrangements, with pertinent remarks on a few lessons to be drawn therefrom. Our correspondent writes:—

The Forces Engaged in the Sham Fights.

Few medical men have any clear idea of how wounded soldiers would be treated in this country in the event of invasion, and therefore an account of what might be described as as a full dress rehearsal, which recently took place at Folkestone, may be of special interest to members of the medical profession, as it was on a much larger scale than has ever yet been attempted. The 2nd London Division of the Territorial Force, some 11,000 strong, under Major-General Vesey Dawson, C.V.O., were encamped in the neighbourhood of Shorncliffe, and as on several days there were sham fights it was decided to have a great many imitation casualties on one day, to give practice to a field ambulance and the members of any voluntary aid detachments (V.A.D.'s) who might be willing to coöperate. A field day had been arranged for Friday, August 18th, between two forces—"Whiteland" and "Greenland"—in the neighbourhood of Cæsar's Camp. As the "Whites" were on the south near Folkestone it was decided to fall out the casualties from this force. "White," as a matter of fact, was defeated, and the number of casualties, if bullets had been used, would have been at least as many as were actually dealt with. Colonel Andrew Clark, K.H.S., administrative medical officer 2nd London Division, was in charge of arrangements of the R.A.M.C. (T.) and Lieutenant-Colonel J. W. T. Gilbert, of Folkestone, of the V.A.D.'s. Each casualty, as he fell to order, was to have attached to him a tally giving a brief description of the injuries he had received, and although this arrangement was not carried out quite as it was intended, nearly 100 officers and men became casualties.

Field Ambulance Work.

The wounded received first aid from the regimental stretcher-bearers, superintended by the regimental medical officers. They were then carried back (or walked back if the injuries described permitted it) until the bearers of the 6th London Field Ambulance were met with. These took over the cases and proceeded to one or other of the two advanced posts of the ambulance, which were situated respectively at Wingate Farm and the "Valiant Sailor." Here they were attended to by the medical officers and men and, when necessary, given beef-tea, &c. They were then placed in the ambulance wagon and a spare motor-car, and taken to the Tent Division (formerly called the Field Hospital) of the Field Ambulance, which was situated about a mile in the rear at Lime Kiln Farm, where there were a fully equipped operating tent and a few bell tents. Here the patients were placed in the bell tents, and urgent operations would have been performed if necessary.

Rest Camps.

Information was then received that severe fighting was proceeding elsewhere, and the Field Ambulance was ordered to evacuate all wounded and march. In the same field as the Tent Division, but at a supposed distance of three miles, there was established the first rest camp of the V.A.D.'s, whence the men of the male V.A.D.'s set off with stretchers to fetch in all serious cases, the others walking (as they would have to do on active service). As the wounded arrived they were taken charge of by a medical man and members of the female V.A.D.'s. Their dressings were readjusted if necessary, and they were taken by carts to the second rest camp, where bivouacs were erected and where they remained until transport was

available. The third rest camp was established at the Black Bull-road Board School, and was of the nature of a temporary hospital. An excellent operating theatre fully equipped was established, and the class-rooms were turned into wards. A careful examination of this rest camp showed that nothing had been neglected; the sanitary veniences were excellent, and the way in which beds and operating theatre had been improvised showed that we can place great reliance on some, at least, of the V.A.D.'s. Each detachment appeared to have its fully trained nurse, and the members carried out her directions faithfully. There was a lack of medical men present, but no doubt plenty would be available if the occasion were a real one. There was no lack of trained cooks, and even every visitor was supplied with hot soup.

In actual warfare the more seriously wounded patients would have been transferred from this temporary hospital to an ambulance train at Folkestone and sent thence to the Territorial General Hospitals, which would be established in London at various institutions, such as the London University or the Prudential Buildings; but as each general hospital has to have at least 520 beds the buildings which are suitable and available are few.

Observations on Various Points.

A rehearsal on this scale allows one to obtain some idea as to how matters would proceed in a real action, and to point out details in which alteration is needed. First, as to the field ambulance: owing to lack of special knowledge of map-reading on the part of its officers and to the absence of compasses, the Field Ambulance took a wrong road, and was therefore very late in arriving at its appointed stations. Other difficulties arose from the fact that for economy the Field Ambulance receives in peace time less than one-third of its mobilisation equipment and forces, and even then its general service wagons and forage cart are not the real things, but hired carts, which are much less convenient. Again, the distribution of the available officers should be such that at the Tent Division at least sufficient officers to undertake operations should be present. The Territorial Royal Engineers fixed up telephonic communication between the three stations of the Field Ambulance, but as this could rarely happen in warfare the Field Ambulances should be put in possession of better means of intercommunication than they at present possess.

Secondly, as to the V.A.D.'s. It was absolutely astonishing to see how well the various detachments (some St. John Ambulance and some Red Cross) which came from all parts of Kent worked together, and their cleverness in improvising whatever came to hand was notable. But a few points need criticism. Four or five nurses are not required to each cart of wounded; men with gunshot wounds would not usually be able to stand up to be dressed, and lightly wounded should be made to walk. But these points are, of course, of minor importance.

Finally, in all cases of sham fights one or two real accidents are to be expected, and that these may be passed back without delay to the military hospital, taking precedence of imitation casualties, they should have special tallies. On this occasion one such case was overlooked.

BRITISH MEDICAL BENEVOLENT FUND.

AT the August meeting of the committee 15 applications were considered, but only very inadequate help could be given as the treasurer reported that the grant account was already overdrawn to the extent of £90. Grants amounting to £96 were made to the most distressing of the cases, so that the total deficit is now nearly £200, and the reserves will have to be still further drawn upon. Numerous appeals are always received during the last quarter of the year, and the committee therefore urgently begs for support to enable them to be dealt with. Contributions may be sent to the honorary treasurer, Dr. Samuel West, 15, Wimpole-street, London, W. Appended is an abstract of the cases assisted:—

Widow, aged 44, of L.R.C.P., L.R.C.S. Edin. Husband's savings exhausted by a five years' illness, ending in death, and applicant's only income is the interest on the money received from a small life policy. Tries to make both ends meet by taking boarders, but at present has none. Two children, aged 10 and 9, the elder at an institution and the younger recently elected to one. Voted £10.

Widow, aged 47, of M.R.C.S., L.R.C.P. No income, no children, and hopes shortly to find a suitable post. Voted £5.

Widow, aged 37, of M.R.C.S., L.R.C.P. Two children, aged 6 and 4, and dependent on a small monthly allowance from a sister and occasional earnings from sewing and painting. Has been obliged to part with most of her furniture. Voted £10.

Widow, aged 41, of M.B., C.M. Aberd. Quite unprovided for at husband's death a few years ago. Endeavours to support herself by letting lodgings. Two children, one at an institution. Relieved four times, £34. Voted £12.

Daughter, aged 63, of late M.R.C.S., L.S.A. Maintained herself as a dispenser until no longer able to find work as such, and now dependent on small occasional earnings by wood carving and slight help from a sister. Relieved five times, £50. Voted £10.

Daughter, aged 60, of late F.R.C.S. Has acted for many years as companion, housekeeper, &c., but for some time past has not been able to obtain a suitable post, and has consequently spent her small savings. Relieved twice, £10. Voted £2, and case to be reconsidered at next meeting.

L.R.C.P. Edin., aged 66. Has been incapacitated by ill health for the last two years, and is dependent on help given by a brother. Children unable to help. Relieved twice, £36. Voted £18.

Daughter, aged 68, of late L.S.A. No income and in very feeble health. Relieved four times, £40. Voted £2, and case to be reconsidered at next meeting.

Widow, aged 55, of L.R.C.P. Irel. Since husband's death has maintained herself by nursing, &c., but has been in bad health for some time past; is now in arrears for rent, and has been obliged to dispose of some furniture and clothing. Relieved twice, £20. Voted £5, and case to be reconsidered in October.

Daughter, aged 55, of late M.R.C.S. No income, and practically incapacitated. Relieved nine times, £85. Voted £12.

Widow, aged 54, of L.R.C.P., L.R.C.S. Edin. Receives slight help from relatives, and earns a few shillings a week by writing for newspapers. Two children, of whom the elder will soon be self-supporting. Relieved six times, £62. Voted £10.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

The Public Health of Calcutta.—In presenting his report for 1910 Dr. T. F. Pearse, the health officer of Calcutta, mentions that in previous reports the population of the city had been estimated on the supposition that an increase had taken place since the Census of 1901, and in the same ratio as in the previous decennial period. When the Census was taken, however, in the present year it was found that actually a considerable decrease had occurred, owing to movement of population into the suburbs. The population, as now estimated for 1910, is stated as 886,000, but the rates of mortality, &c., have been calculated on the population of 1901—viz., 847,796. The slight increase in the past nine years has been due to immigration, there having been no natural increase, but, on the contrary, an excess of deaths over births to the extent of 145,634 during the ten years. The birth-rate was 19·3, a very low figure compared with that for India generally (38·64, mean of the last quinquennium), but in Calcutta females constitute only one-third of the population. The total death-rate was 27·9 per 1000, the lowest recorded for over twenty years; corrected according to the new Census returns, it was 26·7. The reduction is chiefly due to diminished mortality from cholera, plague, and small-pox, and applies to every district in the city. It is noteworthy, however, that the death-rate in the suburban area was 38·0, as compared with 24·8 per 1000 for the urban area, the former having shared in the general improvement to a much smaller extent than the latter. The mortality from cholera (2·13) was the lowest recorded for ten years. Plague also was much less fatal than in any year of the decennium, the death-rate being only 1·4 per 1000. In 1909 there had been a severe outbreak of small-pox; in 1910 the city was almost free from this disease, only 48 deaths having been recorded. It is noted that the age for compulsory vaccination has now been reduced to six months, which ought to reduce the infant mortality in the future. Beri-beri had been prevalent in 1909, and the outbreak continued through the spring of 1910, the total deaths having numbered 171, of which 143 occurred in the four months January to April. Hindus suffered more than Mohammedans, and females more than males. Dr. Pearse does not subscribe to what he calls "the extraordinary theory" that this disease arises from deficiency in the dietary due to the process of milling of the rice and wheat used by the Bengalis. "It does not explain the sudden outbreak at the Alipore Reformatory, and its extension over the city, the subsequent subsidence, and the sudden recrudescence of a still more severe character in the following year (1909), with

a much reduced incidence during 1910. The rice and wheat used by Bengalis have been prepared in the same manner for many generations." Enteric fever appears to be on the increase, but probably this is due to improved diagnosis and the fuller inquiries now made in fever cases. There were 330 deaths, chiefly in the northern part of the city. The ratio is 0·38 per 1000. Malaria has been declining since 1905, the mortality ratio being now only 1·7 per 1000, but there was greater prevalence in suburban Calcutta than in the northern half of the old city. Tuberculosis (chiefly phthisis) caused a mortality of 2·3 per 1000, the incidence on females (3·2) being much greater than on males (1·8). There is little variation from recent years. Dr. Pearse thinks that the chief hope for any reduction lies in improved sanitary conditions, especially in freer ventilation for dwellings; he recommends the establishment of tuberculin dispensaries. The drinking water-supply for Calcutta is filtered through sand-beds at Pulta. The total bacteria found were generally below 100 per cubic centimetre; bacillus coli could be detected in from 1 to 5 c.c. generally, but in the drier months not in 20 c.c. The construction of tanks for storage of water previous to filtration may be taken into consideration. Dr. Pearse draws attention to the very dangerous and out-of-date method of washing the sand for filtration that is still practised; "coolies stand waist deep in an underground tank and stir up the dirty sand in unfiltered river water." This procedure is inexcusable in the capital city of the Indian Empire, and might at any time lead to dangerous contamination of the water. Mechanical sand washers should be provided. Dr. Pearse also recommends the construction of additional sedimentation tanks. Much good work appears to have been done by a female sanitary inspector, who has been employed as an experimental and temporary measure since 1908. It appears, however, that the corporation hesitates to make the appointment a permanent one. This is to be regretted. The great value of these officers is now thoroughly recognised in this country, and in the East there is even greater scope for their employment among the female population. Other important sanitary recommendations made by Dr. Pearse are the construction of model dwellings for the poor, clearance of insanitary areas, improvement of lines of communication, and the provision of a better supply of filtered water for the interior of the native quarters. The sanitary charge of a huge city like Calcutta is, indeed, a task of the greatest difficulty.

REPORTS OF SCHOOL MEDICAL OFFICERS.

Tottenham Education Committee.—Dr. J. F. Butler-Hogan's school report for the year 1910 lays great stress upon the value of the feeding of necessitous school children, but raises the question of the supply of the right kind of food, suggesting the provision of a central cookery depôt from which food could be supplied to all places where meals are served. This would secure an improvement in the quality of food provided, and do away with the possibility of invidious comparison of one district's cooking with another. Of all children for whom medical treatment was considered necessary, 63 per cent. are reported as having received professional attention. The percentage varied in different schools, and even in different departments of the same school, very much in this respect depending upon the cordiality and energy of the teacher's coöperation. Reviewing the whole matter, Dr. Butler-Hogan continues that it is practically impossible for the cases most seriously needing treatment to obtain it, and writes: "It is those diseases which are most serious for the children, which interfere most with attendance, and therefore with the school grant, that are unfortunately left untreated, owing, in many instances, to the negligence of the parents, but often through their sheer inability to procure, in any form, the necessary medical attendance." These considerations lead Dr. Butler-Hogan to consider in detail the whole question of treatment of school diseases, and to discuss from every point of view the question of supplying special treatment in a "school clinic." The report outlines the conditions necessary for the establishment of such a school clinic, these being quoted largely from the report of Dr. L. A. Williams, school medical officer of Bradford, pointing out that objections to such clinics are purely theoretical, and somewhat imaginary. The discussion is thorough and should prove valuable both to medical officers of schools and members of education authorities.

County Borough of Brighton.—The annual report for 1910 of Dr. Duncan Forbes and Dr. J. Lambert, school medical officers, shows that the number of children inspected in Brighton was 6273, and of these 2312 were found to be in need of some form of medical advice or treatment. An interesting survey of the methods available for the treatment of defects shows that a large percentage of children suffer from ailments which are not treated, as a rule, by private practitioners—for example, children suffering from ringworm of the scalp, those in need of spectacles, and those requiring the removal of tonsils and adenoids. It is pointed out that the majority of children requiring spectacles, or the removal of adenoids and tonsils, "are patients of practitioners doing large practices amongst the poor. Even if those practitioners cared to specialise in the required directions, the parents could not afford to pay them adequately for their work. To make it worth doing, therefore, the Education Committee would need to pay a part, if not the whole fee." A consideration of these facts led to a meeting of the local branch of the British Medical Association on Nov. 18th, 1910, when details of a scheme for treatment of school diseases suitable for Brighton were laid before members of the elementary school subcommittee. This meeting dealt with a larger scheme, but a small school clinic is in the fifth year of its existence in Brighton, and is held once weekly on Tuesday afternoons, at 5.30, in a room of the special school. The conditions treated are diseases of the skin and scalp, verminous conditions, and eczema; in addition, blepharitis, conjunctivitis, and certain other conditions are dealt with. Cases of other diseases are sent down for examination by teachers, but these are more frequently dealt with at the Public Health Office. These are the classes of case found to be most neglected in ordinary school work everywhere, and for which ordinary agencies do not suffice. When we add to these the cases previously mentioned, it would seem that there is a distinct field for the clinic quite apart from the ordinary province either of hospital work or private practice. Moreover, the need for dental treatment makes the necessity for the clinic much more pressing. An interesting experiment is that of training girls in domestic work in a model home in which several of the teachers reside, thus securing actuality in the conditions. The girls are required to carry out the whole of the housework, and it is expected that the experience gained will be very valuable in enabling them to obtain employment promptly on leaving school and in equipping them for their own home duties in the future. Investigations have been carried out during the year on the prevention of dust in schools by the application of oil preparations to the floor. The exposure of culture plates has demonstrated that the use of such preparations is a very great improvement upon the ordinary methods of "cleansing" not only floors but furniture. Another experiment is the provision of a special class for "intermediate" children whose development is between backwardness and actual mental deficiency. More elaborate subdivision and special grouping of children are required in school work, and every experiment in this direction is very valuable. It is these intermediate children who are the difficulty, as also in another way are the "semi-deaf" and the high myopes. None of these groups can be satisfactorily taught either in the ordinary or in the special classes; attempts to separate them are therefore particularly helpful.

City of Birmingham Education Committee.—Dr. G. A. Auden's report contains an interesting survey of the ameliorative agencies which have to do with child life, both before and during school age. These include infant health supervision in all its forms, one of them being a guild of mothers, where meals are provided for expectant mothers, and where the children are carefully looked after at birth. During school age there are the special care committees, established in connexion with four schools (voluntarily), the Women's Settlement, and the National Union of Teachers Children's Charity Fund. A list is given of the general curative agencies, hospitals, dispensaries, &c., also of special educational institutions and general ameliorative agencies (among these sanatoriums, the Charity Organisation Society, and a police charity), also after-care committees. The medical officer points out in urging the establishment of care committees, as they already exist in London, that all of these nstitutions affect the schools and should be grouped and coördinated with the schools by means of the care committee organisation. It is also stated that considerable as

the great stream of charity implied by all these agencies is, there are yet great gaps, as, for instance, in the treatment of tonsils and adenoids, defective teeth, ringworm, and eye troubles. The care committees by supplying the coördinating mechanism would make it possible to fill up these gaps, and, as the medical officer says, "would go far in supplying the initial coördination, which is necessary, and would allow the problem to be attacked from the point of view of the home." It must be remembered, however, that in London, where care committees are already established, attempts on the part of the care committees at coördination have not been very successful, and can only be effectual if the school clinic is added—that is to say, the school clinic appears the centre around which all the various ameliorative agencies must be coördinated, the care committee being merely the mechanism bringing the agencies to that point. Voluntary institutions can, in fact, be best used in association with these committees. Experiments on dust prevention in schools have been carried on in Birmingham, and their result points strongly in the direction of the value of oil preparations applied to the floors. A good feature in Birmingham, which other authorities might well copy, is the provision at Floodgate-street council school of a well-equipped school bath. The excellent photograph reproduced gives one a very pleasant impression, as does also, by the way, the picture of the combined hammock for use in infant schools for the "baby room."

East Suffolk County Education Committee.—Interesting comparisons of different parts of the county as regards clothing, nutrition, and defects are made, and some important differences in measles as between town and country school populations are brought forward.

County Borough of Hastings.—The report of the schools in Hastings is chiefly remarkable for consisting only of three-quarters of a page of print. 2770 children were examined, but no special school medical information is given beyond a bare recital of figures.

Great Yarmouth Education Authority.—The table by the school medical inspector, Dr. H. W. Harding, gives an instructive comparison between height and weight and standard for different age groups. Superior physique is found in the superior standard, and this Dr. Harding attributes to higher standard of home life, implying in this "all details entering into the boys' surroundings while out of school."

Hull Education Committee.—By October, 1911, the medical officer reports that the whole of the children attending school will have been inspected. In 1910 18 824 children were examined, 4996 notices to parents regarding treatment issued, but the result was only recorded in 954 cases. A medical register in each department would secure a more adequate record. Some interesting statistics of nutrition are tabulated.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 8146 births and 6368 deaths were registered during the week ending Sept. 2nd. The revised estimate of population of these towns in the middle of this year is 16,157,797 persons. The annual rate of mortality in these towns, calculated on this revised estimate, which had steadily increased from 11·8 to 21·2 in the seven preceding weeks, declined to 20·6 per 1000 in the week under notice. During the first nine weeks of the current quarter the annual death-rate in these towns averaged 16·3 per 1000, while in London during the same period the mean annual death-rate did not exceed 15·3 per 1000. The recorded annual death-rates in the 77 towns last week ranged from 10·4 in Northampton, 11·4 in Barrow-in-Furness, 11·6 in Leyton, and 11 9 in Croydon, to 29·8 in Wigan, 31·4 in Bolton, 33·8 in Burnley, and 36·8 in Stoke-on-Trent. The 6368 deaths from all causes in the 77 towns last week were 200 fewer than the number recorded in the previous week, and included 2617 which were referred to the principal epidemic diseases, against numbers increasing from 268 to 2900 in the nine preceding weeks. Of these 2617 deaths from the principal epidemic diseases no fewer than 2461 resulted from infantile diarrhœa, 58 from whooping-cough, 35 from diphtheria, 34 from measles, 21 from enteric fever, and 8 from scarlet fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases last week was equal to 8·4 per 1000, against 8·8 and 9·4 in the two preceding weeks. The deaths of infants under 2 years of age attributed to diarrhœal diseases in the 77 towns, which had increased from 70 to 2714 in the nine preceding weeks, declined last week to 2461, and caused the highest annual death-rates of 15·3 in Bolton, 16·0 in Grimsby, 16·4 in Bootle, 16·6 in Burnley, and 21·3 in Stoke-on-Trent. The deaths referred to whooping-cough, which had been 46 and 68 in the two previous weeks, declined to 58 last week, and included 16 in London and its suburban districts, 5 in Liverpool, 4 in Newcastle-on-Tyne, 3 in Preston, and 3 in Sheffield. The fatal cases of diphtheria numbered 35, and were equal to the average number recorded during the five preceding weeks; 10 deaths were registered in London, 5 in Liverpool, 4 in Bristol, and 3 in Birkenhead. The deaths attributed to measles, which had been 59 and 54 in the two previous weeks, further declined last week to 34, and was the lowest number recorded in any week of the current year; 6 deaths occurred in London, 6 in Bolton, 5 in Manchester, and 3 in Nottingham. The deaths from enteric fever, which had been 11 and 18 in the two preceding weeks, further rose to 21 last week, and included 3 in Wigan, 2 in Stoke-on-Trent, and 2 in Hull. The 8 fatal cases of scarlet fever was the lowest number recorded in any week of the current year. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had been 1442, 1388, and 1352 in the three preceding weeks, had further declined to 1327 on Saturday last; 168 new cases of this disease were admitted to these hospitals during the week, against 159, 149, and 132 in the three previous weeks. These hospitals also contained at the end of last week 723 cases of diphtheria, 231 of whooping-cough, 161 of measles, and 57 of enteric fever, but not one of small-pox. The 1529 deaths from all causes in London last week showed a decrease of 116 from the number returned in the previous week, and included 73 which were referred to diseases of the respiratory system, against 97 and 85 in the two previous weeks. The deaths attributed to different forms of violence in the 77 towns, which had been 184 and 152 in the two preceding weeks, further declined to 147 last week, and 322 inquest cases were registered. The causes of 35, or 0·5 per cent., of the deaths registered in the 77 towns during the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified last week in Sheffield, Bristol, Bradford, Hull, Newcastle-upon-Tyne, Nottingham, and Portsmouth, and in 48 other smaller towns. The 35 uncertified causes of death last week included 5 in Liverpool, 3 in Birmingham, 3 in Gateshead, and 2 each in Reading, West Bromwich, Coventry, Burnley, and South Shields.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of this year, 752 births and 564 deaths were registered during the week ending Sept. 2nd. The annual rate of mortality in these towns, which had been equal to 14·2 and 15·5 in the two preceding weeks, further rose last week to 17·2 per 1000. During the first nine weeks of the current quarter the annual death-rate in these Scotch towns averaged 14·8 per 1000, and was 1·5 below the mean rate during the same period in the 77 large English towns. The annual death-rates in the Scotch towns last week ranged from 13·4 and 15·4 in Aberdeen and Edinburgh, to 20·1 in Leith and 20·3 in Perth. The 564 deaths from all causes in the eight towns last week exceeded by 55 the number returned in the previous week, and included 134 which were referred to the principal epidemic diseases, against 99 and 114 in the two preceding weeks; of these 134 deaths, 113 resulted from diarrhœa, 10 from whooping-cough, 5 from diphtheria, 4 from measles, 1 from scarlet fever, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 4·1 per 1000, the mean death-rate last week from the same diseases in the 77 English towns having been 8·4. The deaths attributed to diarrhœa, which had increased from 33 to 88 in the four preceding weeks, further rose last week to 113, and included 96 of infants under two years of age; 72 deaths occurred in Glasgow, 11 in Dundee, 8 in Edinburgh, and 6

each in Paisley, Greenock, and Perth. The 10 fatal cases of whooping-cough were 2 less than the number in the previous week, and included 4 in Edinburgh, 3 in Glasgow, and 3 in Aberdeen. The 5 deaths from diphtheria were equal to the number in the previous week, and included 2 in Leith and 2 in Perth. Two of the 4 deaths referred to measles, and the fatal case of enteric fever, were registered in Glasgow. The fatal case of scarlet fever was recorded in Edinburgh. The deaths referred to diseases of the respiratory system in the eight towns, which had been 29 and 41 in the two preceding weeks, declined to 24 last week, and were 23 below the number in the corresponding week of last year. Of the 564 deaths from all causes in the eight towns last week 159, or 28 per cent., were recorded in public institutions, and 14 deaths were attributed to different forms of violence. The causes of 10, or 1·8 per cent., of the deaths in the eight towns last week were not certified; in the 77 English towns the proportion of uncertified causes of death during the week did not exceed 0·5 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 609 births and 462 deaths were registered during the week ending Sept. 2nd. The annual rate of mortality in these towns, which had been 17·1, 19·4, and 19·3 in the three preceding weeks, rose again to 21·0 per 1000 in the week under notice. During the first nine weeks of the current quarter the annual death-rate in these towns averaged 17·5, whilst the mean rate during the same period did not exceed 16·3 per 1000 in the 77 English towns, or 14·8 in the eight Scotch towns. The annual death-rate last week was equal to 25·8 in Dublin (against 17·6 in London), 18·6 in Belfast, 24·5 in Cork, 12·8 in Londonderry, 17·7 in Limerick, and 9·5 in Waterford; whilst in the 16 smallest of these towns the mean annual death-rate did not exceed 17·8 per 1000. The 462 deaths from all causes in the 22 Irish towns exceeded the number in the previous week by 36, and included 153 which were referred to the principal epidemic diseases, against 114 and 133 in the two preceding weeks; of these 153 deaths, 141 resulted from diarrhœal diseases, 7 from whooping-cough, 2 from enteric fever, 2 from measles, and 1 from diphtheria, but not one from scarlet fever or from small-pox. These 153 deaths from the principal epidemic diseases were equal to an annual death-rate of 6·9 per 1000. The mean rate from the same diseases in the 77 English towns was equal to 8·4 per 1000, while in the eight Scotch towns it did not exceed 4·1. The deaths attributed to diarrhœal diseases, which had been 104 and 112 in the two preceding weeks, further rose to 141 last week, and included 126 of infants under two years of age. Fifty-eight deaths occurred in Dublin, 49 in Belfast, 6 in Cork, and 6 in Newtownards. The deaths referred to whooping-cough, which had been 3 and 8 in the two preceding weeks, were 7 last week, and were all registered in Dublin. The 2 fatal cases of enteric fever occurred in Dublin and Belfast, those of measles in Dublin and Newtownards, and that of diphtheria in Dublin. The deaths referred to diseases of the respiratory system, which had been 39 and 30 in the two preceding weeks, were 31 last week. Of the 462 deaths from all causes in the 22 town districts last week 109, or 24 per cent., occurred in public institutions, and 8 deaths were attributed to different forms of violence. The causes of 15, or 3·2 per cent., of the deaths in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes of deaths during the week under notice did not exceed 0·5 per cent. in the 77 large English towns, and was equal to 1·8 per cent. in the eight Scotch towns.

SUNDERLAND AND NORTH DURHAM EYE INFIRMARY.—The extension of the Sunderland and North Durham Eye Infirmary, undertaken in memory of Mr. Thomas Frederick Hopgood, surgeon to the institution, who died in May, 1909, was opened by the Mayor of Sunderland on August 26th. After the ceremony the mayor, on behalf of the vice-president and the general committee, presented a silver rose bowl and some other articles to Captain George Butchart, chairman of the house committee, for his supervision of the work. The cost of the extension has been over £700.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: J. H. Pead to the *Cumberland*, on recommissioning; J. E H. Phillips to the *Superb;* and G. A. Waters to the *Excellent*. Staff Surgeons: H. Hunt to the *Endymion;* J. G. Peebles to the *Dido*, on commissioning; and R. W. B. Hall to the *Sirius*, for voyage out and home. Surgeons: R. F. MacMahon to the *Pembroke*, additional, for disposal; L. L. Greig to the *Cumberland*, on recommissioning; and G. Moir to the *Pembroke*, additional, for disposal.

ROYAL ARMY MEDICAL CORPS.

Major James C. Morgan to be Lieutenant-Colonel, vice S. R. Wills, retired (dated August 30th, 1911).

The under-mentioned officers are seconded for service with the Egyptian Army (dated August 17th, 1911): Captain Robert B. Black and Lieutenant Harry S. Ranken.

Captain E. S. Worthington, M.V.O., now serving in London, has been appointed medical officer on the staff of the Duke of Connaught when the latter proceeds to Canada. Captain R. J. B. Buchanan has been appointed to the Alexandra Hospital, Cosham, as clinical pathologist. Captain D. Coutts has been granted general leave to Oct. 15th next.

Colonel M. W. Kerin, C.B., principal medical officer of the Seventh (Meerut) Division, has taken up duty at Mussooree. Brevet-Lieutenant-Colonel O. R. A. Julian, C.M.G., lately commanding the Military Hospital, and civil surgeon at Kasauli, has taken up duty in the Dublin District on completion of his tour of service in India. Major T. McCulloch, from Mandalay, has been appointed to the medical charge of the Military Hospital at Calcutta. Major E. C. Anderson, from Kuldana, has been transferred to the Military Hospital at Rawal Pindi for duty. Major P. H. Collingwood, from Devonport, has been appointed to the medical charge of troops at Exeter. Captain W. F. H. Vaughan has been transferred from Cosham to Parkhurst. Captain G. E. Cathcart, from Chester Military Hospital, has been placed in medical charge of Trawsfynydd Camp. Captain R. H. L. Cordner, on return from service in India, has been appointed for duty in the Southern Command. Captain D. P. Johnstone, from Liverpool, has been detailed for duty at Ross Camp. Captain A. A. Meaden, on completion of a tour of service at Nasirabad, India, has been posted to the Military Hospital at Fermoy. Captain G. Ormerod has been transferred from Belfast to Londonderry. Captain C. P. O'Brien-Butler, from Purandhar, has taken up duty at Belgaum.

INDIAN MEDICAL SERVICE.

Surgeon-General P. H. Benson has retired. Colonel D. ffrench-Mullen, who will shortly vacate the appointment of Deputy Principal Medical Officer at Indian Army headquarters, has been appointed Principal Medical Officer, Sirhind and Jullundur Brigades. Major L. F. Smith has been appointed to the charge of the Brigade Laboratory at Nowshera. Captain C. H. Cross has been posted to the medical charge of the 15th Ludhiana Sikhs.

His Excellency the Governor of Bombay in Council has appointed Lieutenant-Colonel Ashton Street to be Senior Surgeon and Professor of Clinical and Operative Surgery at the Grant Medical College, Bombay, in succession to Lieutenant-Colonel W. H. Quicke, who has retired. Major J. G. Murray has been appointed Civil Surgeon at Berhampur, Bengal. Major J. M. Woolley has been appointed Senior Medical Officer at Fort Blair. Major R. F. Standage, Bombay, has had an extension of leave granted by the Secretary of State for India. Major J. W. Watson has been appointed Agency Surgeon at Alwar. On return from combined leave of absence home from India Major C. H. Bensley has been appointed to officiate as Superintendent of the Central Jail at Nagpur. Major F. O. N. Mell has been appointed to officiate as Inspector-General of Prisons in the Central Provinces during the absence on leave of Lieutenant-Colonel W. B. Lane. The services of Captain R. T. Wells have been placed temporarily at the disposal of the Government of the Punjab by the Home Department. Captain A. S. M. Peebles has been appointed to officiate as Superintendent of the Central Lunatic Asylum at Berhampur. Captain E. P. Mackie has been posted by the Home Department of the Government of

India for duty in the United Provinces. Captain H. M. Brown has been selected to officiate as Deputy Sanitary Commissioner of the Bengal and Orissa Circle. Captain C. C. Murison has been appointed to officiate as Civil Surgeon and Superintendent of the Lunatic Asylum at Hyderabad.

TERRITORIAL FORCE.

Yeomanry.

Nottinghamshire (South Nottinghamshire Hussars) Yeomanry: Surgeon-Lieutenant William T. Rowe to be Surgeon-Captain (dated July 27th, 1911).

Royal Army Medical Corps.

1st London (City of London) Field Ambulance, Royal Army Medical Corps: The undermentioned officers resign their commissions: Captain Charles A. Lees and Captain Percival G. A. Bott (dated Sept. 6th, 1911). Hans Conrad Swertz to be Lieutenant (dated Sept. 6th, 1911).

5th Southern General Hospital, Royal Army Medical Corps: Major John R. S. Robertson to be Lieutenant-Colonel (dated May 1st, 1911). Captain Thomas A. M. Forde to be Major (dated May 1st, 1911).

For Attachment to Units other than Medical Units.—John William Bell to be Lieutenant (dated July 18th, 1911).

Attached to Units other than Medical Units.—Captain Robert H. Gilbert-Bruce resigns his commission (dated Sept. 6th, 1911).

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant Alexander C. McKillop resigns his commission (dated Sept. 6th, 1911).

The undermentioned Lieutenants are confirmed in their rank: Arthur H. Habgood, Alexander C. Court, Clarence E. Greeson, John P. Charnock, William Crymble, Laurence M. Routh, Sydney J. Higgins, Robert H. Nolan, Leonard W. O. Taylor, Reginald Fisher, John H. C. Grene, and Harold F. Vellacott.

The undermentioned to be Lieutenants (on probation): Cadet Lance-Corporal Charles Hope Carlton, from the University of Oxford Contingent, Officers' Training Corps (dated July 31st, 1911). Cadet Corporal D'Arcy Power, from the University of London Contingent, Officers' Training Corps (dated August 7th, 1911).

VACCINATION IN THE ARMY.

In the House of Commons recently the Under Secretary of State for War, replying to Mr. John Ward, M.P., said that with the exception of those bearing distinct marks of small-pox all army recruits were vaccinated, unless in the case of a recruit joining from the Special Reserve the operation was certified to have been successfully performed during his service in this force. Once a year, in March, medical officers were required to satisfy themselves that every man, woman, and child under their charge was sufficiently protected by vaccination. There had been only one admission to hospital for small-pox amongst the army at home for the last five years, and that was in the case of a woman. It was well known that the period of immunity after vaccination or revaccination varied, and those individuals whose period of immunity commenced to decline earlier than usual were liable to fall victims to the disease, as was the case with the woman mentioned. Accordingly, owing to the chance of there being individuals present in the barracks whose period of immunity was for various reasons declining or becoming evanescent, it was considered necessary that all persons living in or associated with barracks should be adequately protected against small-pox.

THE UNITED STATES NAVAL MEDICAL BULLETIN.

This quarterly bulletin is published under the authority of the Surgeon-General of the United States Navy "for the timely distribution of such information as is deemed of value to the medical officers and the hospital corps in the performance of their duties." The issue of July, 1911, contains a very useful compilation by Surgeon E. M. Shipp, U.S.N., of our present knowledge of tropical diseases in their relation to the eye, in which he divides them into five classes—viz., those due respectively to bacteria, moulds, protozoa, helminths, and toxins and other causes. He discusses each member of these five groups separately. A report, a sequel of a previous communication, from the United States Naval Hospital, Norfolk Va., by Passed Assistant Surgeons G. B. Trible and H. A. Garrison, U.S.N., records and discusses eight cases in which the conclusion is arrived at that the treatment of syphilis with salvarsan is of particular advantage in the service, either alone or in combination with mercurials. In the primary and secondary stages (the most common ones in the service) the rapidity of return to duty on treatment with salvarsan is remarkable. The following is recommended as an ideal treatment: "In primary lesions, thorough excision as soon as diagnosed, two intravenous administrations of salvarsan at intervals of ten days, followed by an active mercurial treatment by injection or inunction for a period of three months. In the secondary and tertiary stages this treatment should be combined with mercury and potassium iodide." Passed Assistant Surgeon H. Butts, U.S.N., discusses the mental examination of 50 recruits who became insane soon after enlistment, and urges more time for the inquiry into the past history of candidates, so as to exclude alcoholics, drug fiends, sexual perverts, and mental defectives. Oblique inguinal hernia (almost the only type found in the United States navy) is discussed with reference to diagnosis and treatment by Passed Assistant Surgeon B. F. Jenness, U.S.N. From the United States Naval Medical School laboratories comes a report of special interest to naval surgeons, on the Davainea Madagascariensis in the Philippine Islands, by Passed Assistant Surgeon P. E. Garrison, U.S.N. Passed Assistant Surgeon M. E. Higgins, U.S.N., arrives at the conclusion that a negative reaction in Noguchi's complement fixation test "may mean either that the individual has never had syphilis, that he has had syphilis and been cured, or that owing to treatment the action has disappeared," while "weakly positive and faintly positive reactions without strong clinical evidence of lues are not to be accepted as bespeaking a positive diagnosis." Among many other interesting communications Passed Assistant Surgeon W. A. Anguin, U.S.N., describes a somewhat complicated but apparently effectual method of treating fracture of the lower jaw by wiring.

Correspondence.

"Audi alteram partem."

SEA-WATER: ARE ITS CURATIVE EFFECTS DUE TO RADIO-ACTIVITY?

To the Editor of THE LANCET.

SIR,—In THE LANCET of August 5th, p. 361, Dr. I. C. Maclean and Mr. L. de C. Harston record a case of toxæmia, presumably of intestinal origin, which cleared up in a remarkable manner under injections of sea-water. They state that Dr. H. D. Rolleston, who saw the case in consultation, regards the good effect as possibly due to the large amount of sodium chloride introduced into the tissues. Other writers have also held this view. Leary, for example, states that the action of isotonic sea-water solution is practically neither more nor less than that of physiological saline.[1] If this be indeed the case, then the careful process of collection and preparation becomes simply an elaborate farce.

But is the action, osmotic or chemical, of sodium chloride the complete explanation of the therapeutics of sea-water? Discussing, some months ago, the treatment of mucous colitis,[2] I suggested that radio-activity may play a part in the effects produced. Since then further investigations have strengthened this belief, and it may be of interest to state briefly the facts on which I base my conclusion.

In the course of my practice I receive many cases of lupus and of indolent leg ulcer for treatment by X rays. Amongst other work obstinate cases from the Auckland Union Infirmary come under my care, whereas the simple examples are treated by other methods. Through the courtesy of Mr. Mark A. Wardle I was enabled to watch the progress of some of these latter, *pari passu* with that of my own cases under X rays. The clinical course and results, allowing for difference of severity, were so strikingly similar that I was led to the conclusion that the same agent—radio-activity—might be at work. Beyond a casual reading of Robert

[1] Leary: Boston Medical and Surgical Journal, August 18th, 1910.
[2] Practitioner, May, 1911.

Simon's article[3] I had not till this time taken much interest in the therapeutics of sea-water; but I have since consulted all the literature available to me on sea-water injection, sea voyages, and radium-water therapy.[4]

I find that the two agents agree in the following properties: 1. General tonic and stimulant action; this is produced with great rapidity and thus differs from the slow effects obtained by medicinal tonics. 2. The production of diuresis, and alteration in the output of urea and uric acid. 3. Continued administration results in gain in body weight, with accompanying speeding up of metabolism, increase of appetite, and increased output of CO_2. 4. Therapeutically, marked benefit is produced in neurasthenia, intestinal auto-intoxication, certain skin diseases, chronic joint troubles, early tuberculosis, and some cases of albuminuria. 5. Radium-water, whether artificially prepared or obtained from natural springs, owes its activity to dissolved "emanation," which is a gas. This gas which, under natural conditions, is being constantly renewed, loses its activity fairly rapidly, declining to half value in less than four days. It may be removed from the water by boiling for some time. *The therapeutic value of sea-water is destroyed by heat; nor is it of any use after it has been kept three weeks.* Of the truth of these statements I have had ample confirmation in my own practice.

A pertinent question is, Does the physicist recognise the presence of radio-activity in freshly gathered sea-water? At the recent meeting of the British Medical Association in Birmingham, Professor Farr (chair of Physics, Christchurch, N.Z.) gave an address on the Effects of Radio-active Water on Fish.[5] In connexion with this subject, I mentioned to him my views on sea-water treatment, and he informed me that ocean water *is* to some small extent radio-active, and that this activity is mostly due to dissolved emanation.

I submit, therefore, that in view of the fact that sea-water is radio-active, and that its physiological and therapeutic effects so strikingly resemble those of radium water, there is very good reason to believe that its curative powers are, at any rate in great part, due to the emanation which it contains. In radio-activity we have an agent capable of producing all the diverse and powerful effects which are claimed for sea-water treatment—effects which range from the cure of lupus to the banishment of an obscure toxæmia, such as that described by Dr. Maclean and Mr. Harston. So far as I am aware, no salt or combination of salts could accomplish such results.

If my theory be correct, its practical importance is obvious. Ocean water is kept constantly radio-active, probably as a result of submarine volcanic processes. Once removed, however, it rapidly loses its virtue. Hence, it is only freshly collected water which is of value; to get the best results we should use it within a week. Those who do not observe this rule cannot be said to give the method a fair trial; they may well find sea-water of no more value than salt solution.

I am, Sir, yours faithfully,

FRANCIS HERNAMAN-JOHNSON, M.D., Ch.B. Aberd.,
R.N. (retired).,

Bishop Auckland, August 15th, 1911.

A QUESTION IN EUGENICS.

To the Editor of THE LANCET.

SIR,—Many of your readers have carefully followed the discussion of this question in your pages. We have, I trust, derived benefit, but the actual enlightenment is less than many of us hoped for.

The original question was specific and definite. Is a father, acting in the interests of an epileptic son under age, entitled to procure an operation which will prevent that son from becoming a father? It is a question that will, before long, demand an answer. But it has not so far received an answer. The stream of heart-felt eloquence at high pressure directed against your columns seems, indeed, to have washed the question away. Certainly it is satisfactory to know that there are members of the profession who wear their hearts upon their sleeve, and still more satisfactory to be assured that the emotions contained in those hearts are of so lofty a character. But we never doubted it. These emotions are beside the mark. The question is one that can only be discussed profitably in the dry light of intelligence. Moreover, it demands precise knowledge.

It is surprising to find that several of your correspondents imagine that a question of this kind can be dismissed by talking about a supposed abstract conflict between the "individual" and the "race." A concrete question demands a concrete answer. In this case the possible father is an "individual"; the possible children would also be "individuals." The children of this father are likely to involve a special burden of anxiety and expense, while his own condition will render him unfit to cope with that burden. Under such conditions the children are likely to be a misery to themselves and to others. There is no conflict here between the "individual" (the possible father) and the "race" (the possible children). Their interests are identical. Evidently it is dangerous to plunge into academic disquisitions of a pseudo-metaphysical character when asked to reply to a simple concrete question.

There is another point on which some of us feel that we have been led astray. No doubt there is a wide range of variation in what the phrenologists call philoprogenitiveness. But in some of your correspondents this bump must be developed to a really alarming extent. It is good to have children, so long as one is reasonably assured that those children will be well-born, and that one is able to provide for them. But it is another matter to have children at all costs. We must not allow our philoprogenitive impulses to grow so hysterical that we become unable to see that many people remain happy and lead useful lives without children, and even with no prospect of children. I have elsewhere recorded the case of a medical man who, having as many children as he desires and wishing to avoid the unpleasant routine of preventive methods, has had vasectomy performed with results that are highly satisfactory both to himself and his wife. Now, many will consider that in such a case the operation was not called for. But supposing the subject had been a man of profoundly neuropathic constitution, there ought surely to be little difference of opinion, even though vasectomy had been performed at the outset of sexual life. In many cases, it is probable, sterilisation and freedom will prove the only proper alternative to isolation without sterilisation. "Life under such conditions is not worth living," exclaims one of your correspondents; he would rather retire to a colony for degenerates. Very well. *Chacun à son goût.*

It is not easy to feel enthusiasm about sterilisation, any more than about any other operation for the relief of suffering humanity; it would be better to avoid the need for it, and its scope must always be limited. It is surprising, therefore, to find that one of your correspondents has so much faith in the enormous effects of asexualisation that he fears lest, by abolishing human suffering, it will remove the need for moral helpfulness. One may note in passing that the "moralist" who would perpetuate human misery in order to cultivate his own moral helpfulness is a "moralist" who must be severely isolated in inverted commas. (Let me add that I am sure he does himself an injustice and is the victim of his own controversial ingenuity.) But this fear is uncalled for. Everyone who is acquainted with the actual conditions of things to-day knows that, far from being threatened by the disappearance of the need for moral helplessness, we are being overwhelmed by the burdens involved by our moral helpfulness. The favour with which sterilisation is now viewed is largely due to the hope that, if wisely and discriminately carried out, it may help us to cope with those burdens.

It is not, I believe, quite correct that sterilisation has been "legalised" in Switzerland. The reference is probably to the operations performed at the Cantonal Asylum at Wil. (The portion of the sixteenth annual report of the asylum dealing with the matter is reproduced in the *Psychiatrisch-Neurologische Wochenschrift*, No. 2, 1909.) In these cases the operation (actual castration), carried out on two men and two women, was performed not only by agreement with the relatives and the local authorities, but with the eager consent of the patients themselves, who were thus enabled to return

[3] Robert Simon: "Injections of Sea Water," Medical Annual, 1910.
[4] Amongst writings consulted were: "Sea Air and Sea Baths," Quain's Dictionary of Medicine; "Treatment of Rheumatism by Radium," Professor His, Brit. Med. Jour., Feb. 4th, 1911; Papers on Radium Emanation by Armstrong and Saubermann, British Medical Association, Birmingham, July, 1911.
[5] See THE LANCET, August 12th, 1911, p. 446.

to freedom and to work. No compulsion being exercised, no legislation was necessary. This is as it should be. There are very serious objections to compulsory sterilisation.

This discussion has made it clear not only that it is desirable (let me repeat) to cultivate the dry light of intelligence, but also that an extended knowledge of the elementary facts of sexual physiology and psychology would be highly advantageous. Here we see a medical man who apparently confuses vasectomy with castration; there another who believes that vasectomy is fairly comparable with crypt-orchidism; again a third who, one suspects, imagines that sterilisation involves impotence. It is also evident that some among us, however young in years, are still living in the past, not realising what men and women are thinking and doing to-day, nor the new ideals which are inspiring them.

In these matters of eugenics the growth of both general and professional opinion (even since the Royal Commission on the Feeble-minded issued its report three years ago) is most remarkable to those who watch the development of opinion. It is idle to ignore it.

I am, Sir, yours faithfully,

West Drayton, Sept. 4th, 1911. H. HAVELOCK ELLIS.

NATIVE NURSES IN SOUTH AFRICA.

To the Editor of THE LANCET.

SIR,—In a South African newspaper, the *East London Daily Dispatch*, a few weeks ago there appeared an extract from a letter said to have been published in THE LANCET. I have not been able to trace the letter in your columns, but as I presume it must have appeared I should be glad to be allowed a little space to reply to it. The writer says that the native probationers in training in this hospital "are stated to compare very unfavourably with European probationers," and the inference from his letter is that they are so unsatisfactory that no hospital will employ them. The fact, however, is that with one exception the colonial hospital authorities have never been willing to give these nurses a trial. That one hospital has employed two and is now wanting another.

It is quite true that a native girl has a longer hill to climb than a European girl before she can become a good nurse. Her home training usually is not so good. Studying in English is also a difficulty for probationers whose home language is not English. But some of our probationers have become very fair nurses, and in the work of nursing natives they, of course, have a great advantage over European nurses, who often cannot speak the patient's language. We are hoping to find employment for our native nurses under Lady Gladstone's District Nursing Scheme in memory of King Edward. In this scheme special provision is being made for this purpose, and I hope none of your South African readers who may be in a position to forward the native section of the scheme will be deterred from doing so by the letter to which I have referred. One of our nurses has for several years been engaged in district nursing and her work has been favourably commented upon both by her employers (a colliery company) and by the public health authorities.—I am, Sir, yours faithfully,

NEIL MACVICAR, M.D.,
Medical Superintendent, Victoria Hospital, Lovedale Mission, South Africa.

*** The subject was referred to in our columns on July 8th, but the words quoted were not used. We have pleasure in publishing Dr. Macvicar's letter.—ED. L.

TATTOOING *v.* VACCINATION.

To the Editor of THE LANCET.

SIR,—Curiously enough, I was just on the point of writing to you on the subject of tattooing in connexion with vaccination, when I read the letter of your correspondent, "E. A. A.," on the subject in THE LANCET of August 26th, p. 664. My object was to tell you that I had recently been informed by a time expired non-commissioned officer, late of the Indian army, that at several stations where he had served medical officers repeatedly told the men that they need not be vaccinated if they were tattooed, and he himself being well tattooed had been exempted from compulsory vaccination.

The attention you are drawing to the subject ought to test the truth of such stories (personally I have absolute confidence in the truth of my informant) and bring the matter to the attention of those responsible. My informant added that men who agreed to allow themselves to be tattooed were granted 13 or 18 days (I forget which) relief from duty for the express purpose!

I am, Sir, yours faithfully,

J. Y. W. MACALISTER.

Royal Society of Medicine, Cavendish-square, W., August 31st, 1911.

SPONTANEOUS COMBUSTION OF METHYLATED SPIRIT.

To the Editor of THE LANCET.

SIR,—With reference to the letter of Dr. John J. Robertson, in THE LANCET of August 12th, p. 475, may I record a somewhat similar incident that has occurred here? On August 1st a lady rose to make a cup of tea at 6.15 A.M. The spirit lamp (with wick) was standing on the floor near the grate. Directly she took the cover off it flared up, and she was burned rather severely about her face and ear. The lamp had not been used since the morning before. A box of matches was on the mantel-piece, but had not been touched. The window was open top and bottom, but the sunlight was streaming through the glass on to the lamp. The patient told me that a similar accident happened ten years ago to her cousin. The lamp in that case was standing in a bay-window, and its ignition was attributed to the sunlight.

I am, Sir, yours faithfully,

W. J. ERNELY SUMPTER, M.D., &c.

Sheringham, August 29th, 1911.

A DERMOID CYST OF THE TESTICLE.

To the Editor of THE LANCET.

SIR,—Dr. Ernest E. Hughes's statement, in recording a case with the above title in last week's number of THE LANCET, that "a left-sided testicular dermoid has yet to be recorded," presumably means in English. Of the cases collected by Wilms and published in 1896, the side affected was stated in ten cases and was the left in four of them.

I am, Sir, yours faithfully,

F. J. F. BARRINGTON.

Medical School, University College Hospital, W.C., Sept. 4th, 1911.

A DISCOVERY IN REGARD TO THE FUNCTIONS OF THE KIDNEY: A CORRECTION.

To the Editor of THE LANCET.

SIR,—I trust you will allow me to correct an error in the Croonian lecture delivered before the Royal Society on June 15th by Professor T. G. Brodie, which I have only just noticed.

The "new conception of the glomerulus" of the kidney offered by Professor Brodie was discovered over 30 years ago by my brother, Dr. A. W. Smyth of New Orleans (better known in connexion with the first successful operation for subclavian aneurysm by tying the vertebral artery for the first time, and mentioned at length in Erichsen's Surgery and by Sir Frederick Treves and others). The discovery in regard to the function of the kidney was published in a pamphlet at the time and appears in the "American Encyclopædia of Biography" and elsewhere.

A. W. Smyth showed that there was no communication between the Malpighian corpuscle and the uriniferous tubules, as taught by Bowman; that there was no filtration; that the water reached the tubules by their own epithelial cells; that the glomerule was a vascular hydraulic ram acting with such force, as in one instance, to push a calculus half an inch in diameter down a ureter.

I am, Sir, yours faithfully,

WM. WOODS SMYTH,
Fell. Med. Soc. Lond., &c.

Maidstone, Sept. 1st, 1911.

ACUTE MANIA A COMPLICATION OF MEASLES.

To the Editor of THE LANCET.

SIR,—The few text-books which make any mention of such a complication of measles as acute mania only allude to it in the briefest possible manner, so that the following account of a case may be of some interest.

The patient was a well-built, well-nourished, strong, active woman aged 22 years. No history of disease of the nervous system or of mental disorder could be discovered amongst her relations past or present There was nothing of interest in the past history of the patient, who was one of a family of six. The attack of measles began in the usual way with nasal catarrh. Menstruation began two days previously and lasted four days and was normal in every way. Koplik's spots were seen quite distinctly on the second day, when the morning temperature was 100·2° F. The rash appeared on the evening of the third day, and when fully developed was very characteristic. It was first noticed behind the ears, and was not well out on the face until the evening of the fourth day. It had disappeared on the eighth day. The morning temperature was 99 8° on the third day, 102·8° on the fourth, 101·6° on the fifth, 99·2° on the sixth, and 98·4° on the seventh and eighth. There was never any earache, vomiting, diarrhœa, headache, or sore-throat. There was never any evidence of lung trouble beyond the bronchial catarrh usual in measles, which was not at all severe in this case. There was a good deal of injection of the conjunctivæ on the fourth day, but this soon abated. The eyes were bathed every four hours with boric lotion. At the end of a week the patient seemed to be on the high road to a rapid and complete recovery. She was hungry and cheerful. She had slept well for two nights, and showed no signs of the illness beyond a natural feeling of weakness.

In the light of after events there is an inclination to think that the patient was rather excited on the morning of the eighth day, but had she recovered from the measles in the ordinary way it is probable that no one would ever have recollected the excitement. About 9 P.M. on the eighth day she quite suddenly asked whether she would be well enough to go to a dinner party with some friends that day fortnight. The question aroused some interest because the day was Sunday and the friends were not people who were at all likely to give a dinner party on the Sabbath, and also no mention of any dinner party at their house had been made by anybody. However, nothing more unusual happened until about midnight, when the patient, who had been lying quiet in bed, though not asleep, for about two hours, suddenly sprang out of bed and literally bundled an old servant, who was dozing in a chair by the fire, neck and crop out of the room and downstairs before she had time to realise what was happening. At 12 30 A M the patient was sitting up in bed talking incessantly and incoherently. At intervals she made frantic struggles to get to the fire, and it was with considerable difficulty that two people were able to keep her in bed. Her face was flushed, her eyes bright and sparkling, her temperature 99·2°, pulse 96, and respirations 24. There was nothing abnormal to be detected in the thorax or abdomen. The pupils reacted well to light; the knee-jerks were normal; urine had been passed about 10 P.M.; the bowels had been open after an aperient the previous morning; the tongue was tremulous and coated with white fur. The patient was labouring under a delusion that all her relatives were devils, and she consigned them all, individually and collectively, to the nether regions in extremely vigorous language. She was given 40 grains of bromide of potassium and in about an hour she became much quieter so long as her relatives did not approach her. Any attempt on the part of any of them to do this irritated and excited her extraordinarily. From 2 A.M. to 5 A.M. she remained fairly quiet though not asleep, but about 5 A.M. she became as excited again as she was at midnight. After another dose of bromide there was comparative peace until about 9 A.M., when another phase of excitement began. There was neither sugar nor albumin in the urine. There was nothing abnormal to be seen with the ophthalmoscope. There was no nystagmus, no strabismus, no deafness, no tremor of the hands, and no anæsthesia or hyperæsthesia of the skin could be discovered. Forty grains of bromide of potassium were given every four hours, and during the day the patient was not violent, though at times she became very excited, and all day she was quite irrational. She took sloppy food well. The temperature was 99·4° in the morning and 100·8° in the evening. Thirty grains of chloralamide were given about 10 P.M., but the patient never slept at all during the night. Most of the time she talked incessantly, and two or three times was quite violent. On the tenth day a dose of 30 grains of bromide of potassium with 15 grains of chloral hydrate was given every four hours. The temperature was 99·8° in the morning and 100·6° in the evening. The face was much less flushed and was almost expressionless instead of being bright and excited. A daily dose of an aperient had to be given to overcome the constipation. The patient's main delusion now was that the doctor was Jesus Christ.

On the eleventh day the patient was a good deal worried by hallucinations of sight and hearing; and she imagined that she was the chief of sinners. She was quieter but very morose. Her memory seemed completely in abeyance. The morning temperature was 99·2° and the evening 99·8°. The pulse was 84. On the twelfth day the chief mental trouble was the appearance of pronounced erotic symptoms. When the doctor tried to put his stethoscope on her chest she flung her arms round his neck and tried to drag him into the bed. A Widal reaction proved negative. Sloppy food was taken well. The temperature was 99·0° in the morning and 99·6° in the evening. The chloral and bromide were still continued, but the patient had only had about four hours' sleep during the last four days. The erotic symptoms persisted for four days and then gradually subsided, and at the same time a gradual general improvement began. More sleep was obtained, the restlessness diminished, and the delusions disappeared.

At the end of three weeks the chloral and bromide were given up and occasional doses of chloralamide were given to ensure a good night's rest. The patient was free from delusions but was inclined to be melancholic. She took no interest in what went on around her, and her intellect seemed to have relapsed into the condition of that of a child of four. She answered questions childishly and was quite pleased when a book of nursery stories was read aloud. The presence of her relatives no longer worried her, and so they were readmitted to her room which they had not entered for ten days. At the end of a month there was a decided improvement, though there were occasional fits of depression, and a dose of chloralamide had to be given occasionally.

The patient began to get up soon after this, and though rather weak physically soon picked up strength. She went away to the seaside at the end of six weeks and made steady progress. She became more cheerful and much less childish. She amused herself with sketching and simple games, and took a good deal of walking exercise, but was incapable of any sustained mental effort for nearly six months, and her movements were performed in rather a jerky manner. No hypnotic was given after two months. Nine months after the onset of the measles the patient was quite herself again in every way and no traces of the illness remained.

I am, Sir, yours faithfully,

Sept. 2nd, 1911. A PHYSICIAN.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

A Nursing Home for Edinburgh.

A NEW nursing home for Edinburgh, Leith, and country districts for patients of limited means, which is to be established in Chalmers-street, Edinburgh, is the outcome of the successful experience of the working of the small nursing home of 12 beds in Rutland-square, in the development of which Dr. D. Chalmers Watson took an active part. For the past few years this institution has shown a working profit of £100, and all the original capital outlay has been paid up. The gradual growth of confidence, following on the characteristic Scotch caution with which the Rutland-square home was at first regarded by the Edinburgh medical men, led Dr. Watson to suggest this larger scheme, which has developed under the auspices of the Edinburgh branch of the British Medical Association and the Leith

Medical Practitioners' Association to the region of practicability. A block of three large houses in Chalmers-street has been secured, which will be converted into a well-equipped nursing home, with all modern facilities for the diagnosis and treatment of disease as soon as the necessary sum of £10,000 is in hand. The committee first appealed for donations on March 29th. By April 12th the sum of £3600 had been secured; by May 6th, £5600; by June 16th, £7300; by July 8th, £8600; and now only a balance of £800 is still required. Donations only are asked for; subscriptions will not be required, as it is confidently expected that as soon as the home is open it will become self-supporting. The aims of the home are best described in the following words of Lord Balfour of Burleigh:—"The very poor have a chance of getting assistance in our best hospitals. Those in the higher grades of the social scale can provide it for themselves, but between these two extremes there are many who, while they can, and ought, and are indeed willing to pay something, are quite unable to meet the whole expense of operations and a long residence in nursing homes." The proposed nursing home will contain 50 beds—viz., 18 at the rate of 1 guinea a week, 18 at 2 guineas, and 14 (in single rooms) at 3 guineas. Admissions at the 1 guinea rate must all be made on the recommendation of the medical adviser as being cases suitable for admission at this rate. Both sexes will be received, and for either medical or surgical ailments, and they will be attended by any qualified practitioner at their own selection. The charges include all maintenance and nursing, the patients being responsible for the fees of their medical attendants. The scheme has received the cordial approval of the council and executive committee of the City of Edinburgh Charity Organisation Society. Lord Dunedin is the chairman of the general committee, Mr. Richard Lodge is chairman of the executive committee, while Mr. John L. Somerville, of 6, South Charlotte-street, and Dr. Watson are respectively treasurer and secretary.

Strichen Hospital: Local Government Board Inquiry.

For some considerable time past trouble has been experienced in the working of the Strichen infectious diseases hospital. The hospital, which serves a wide radius, from as far south almost as Ellon, seawards to Boddam, and north-west to Aberdour, is managed by a subcommittee of the Deer district committee of the Aberdeenshire county council. Two medical practitioners in Strichen, Dr. G. S. Trail and Dr. J. H. Stephen, some 15 months ago were appointed medical attendants at the hospital for alternate periods of a year each. According to this arrangement Dr. Trail should have been taking up duty in place of Dr. Stephen in May last. On April 29th of this year the hospital subcommittee met and resolved to ask Dr. Stephen to continue in office after Whit-Sunday next (subject to the existing condition of three months' notice), and instructed the clerk to intimate this resolution to Dr. Stephen and to Dr. Trail. This action of the subcommittee was objected to by Dr. Trail's law agent as being illegal, and has given rise to repeated acrimonious discussions in the district committee. Eventually it was decided to communicate with the Local Government Board and ask that an inspector be sent down to report on the whole working of the hospital. This was done, and the inquiry began on August 29th. The commissioners who held the inquiry were Dr. T. F. Dewar, one of the Local Government Board's medical inspectors, and Mr. Alexander McKinna, of the Public Health Department of the Board. The inquiry was held in the Victoria Hall, Maud, on August 29th and 30th, and was conducted in private. All the members of the hospital subcommittee were cited to appear as well as Dr. Trail, Dr. Stephen, Dr. J. P. Watt (medical officer of health for the county), the matron of the hospital, and others. It will probably be some considerable time before the result of the inquiry is made known.

Accident to a Medical Man.

When returning from a visit to a patient on the evening of August 31st, Dr. Andrew Fowler of Ellon, who was riding a motor cycle, met a motor whose lights he mistook for those of a couple of cyclists, with the result that he struck the splash-board and was thrown with great force from his machine. Fortunately the car was travelling slowly at the time, and on his being conveyed home it was found that his injuries were confined to severe bruises and shock.

Perthshire Fever Accommodation.

At a meeting of the Perthshire Highland district committee, held on August 26th, it was reported that the net cost of the county fever hospital for the past year was £1765, the proportion payable by the Highland district being £424. It was stated that only four patients had been sent from the district last year, while 150 patients were sent from Perth district at a cost of £580. It was explained that the contributions from the district had nothing to do with the number of patients sent, and the fact that there were so few was testimony to the health of the district.

Sept. 5th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Notification of Births in Dublin.

THE Notification of Births Act was adopted by the city council of Dublin last year, and came into operation on Nov. 1st, 1910. Sir Charles Cameron, in his annual report as medical officer of health, gives some information regarding its working during the first two months. Although the duty of notification is put by the Act primarily on the father of the child, it is noticeable that by far the greater proportion of births was notified by medical men and nurses. The total number of births notified was 628, of which 251 were notified by medical men, 312 by midwives and nurses, and only 53, or about 8 per cent., by parents. Inasmuch as (to quote Sir Charles Cameron), "the object of the Act is to give advice where necessary to mothers of the poorer classes on the feeding and rearing of infants," it is important to know how this duty was carried out by the sanitary authority. The figures concerning the number of visits paid by the lady sanitary inspectors, as given in the report, are self-contradictory, but we learn that 464 first visits were paid and 238 re-visits. The number of re-visits is very small and must be of little use in guiding the mothers in the rearing of the babies. If such visits are to be of use they should be regularly paid, and be maintained until the child is at least a year old. It is noticeable that in 408 of the cases visited breast-feeding was practised. The reports of the lady sanitary inspectors show that they realise the duties of their work and that they are able to fulfil those duties tactfully.

Death of Mr. J. C. Sellars.

The death occurred recently of Mr. J. C. Sellars, a medical man of Dundalk, and coroner for the county Louth. In former years he was a crack rifle shot, and was a member of teams representing Ireland in international competitions.

Bequest by Sir G. P. O'Farrell.

The will of the late Sir George Plunkett O'Farrell, Inspector in Lunacy, has been proved, his estate being valued at £20,295. In the event of his son and daughter dying without issue, half this sum is to go to the Irish Medical Association to form a "Sir George O'Farrell Fund" for the benefit of the widows and children of medical men dying destitute.

Health of Belfast.

At the monthly meeting of the city council of Belfast held on Sept. 1st the health report for the five weeks ending August 19th showed the death-rate of the city from all causes during that period to be 16·4 per 1000, as compared with 14·0 in the preceding month and 15 8 in the corresponding period of 1910. The zymotic death-rate was 4·1, as compared with 3·3 in the previous month, the increase being due almost entirely to diarrhœa, which caused 90 85 per cent. of the deaths from zymotic diseases. An unfavourable feature of the report is the increased notifications of enteric fever (of which there were 18 cases), and it is still more unsatisfactory to find that no cause can be assigned for this reappearance of the disease, and that the cases are scattered throughout the city.

Scarcity of Water.

All over the north of Ireland, in both urban and rural districts, there is a great scarcity of water, a very rare phenomenon in our part of the world. In many of the provincial towns the reservoirs are empty, and the city of Belfast since Sept. 4th has been placed on a short supply—that is, from 7 P.M. to 8 A.M. the water is cut off. It is clear the

water commissioners will be obliged to build new reservoirs in the Mourne mountains; they seemed never to have anticipated such a dry season as the present one. As an indication of the dryness of the year, it may be mentioned that in August there were only 2·54 inches of rain, while in the same month of 1910 the rainfall was 6·18 inches, the average for the past 36 years in that month being 4·33 inches. Up to the end of August the rainfall for the whole of this year was 18·55 inches, as against 31·78 for 1910. Owing to the low state of the rivers many salmon and trout have been killed by flax-water (that is, the water coming from holes in which the flax is "retted"), while, still worse, in certain places, such as River Roe, county Derry, poachers have poisoned the water.

Disease in Newtownards.

Mr. D. Jamison, medical officer of health of Newtownards, county Down, owing to the prevalence of English cholera and measles in that town has recommended the temporary closing of the schools.

Sept. 5th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A New Use for Radium.

NEW applications for radium in the relief or cure of disease, and particularly of those forms of disease hitherto lacking any efficacious treatment, are being diligently sought. Dr. Dominici and Dr. Chéron are the latest contributors in this field. These authors have claimed to have obtained considerable amelioration, and even cure, of deep extra-pulmonary tuberculous lesions, such as chronic adenopathies, costal caries (in this case in association with Dr. Barbarin), and fistula consequent on incomplete extirpation of bacillary foci, by the introduction into the tuberculous tissues of silver tubes containing radium. These observations have demonstrated to the authors the superiority of the procedure. The efficacy of radium-therapy in regard to certain tuberculous lesions that have hitherto shown themselves rebellious to medication has, they say, been demonstrated. The authors conclude from their observations, not that radium-therapy is always, and necessarily, more valuable than other modes of treatment in tuberculous lesions, but that there is sufficient encouragement to continue the study of radium-therapy, combining it with surgical methods and the use of various physical agencies, such as X rays, hot air, and diathermia, as well as hygienic, drug, and orthopædic measures.

The Legal Regulations for Distributing Serums.

France has a law regulating the preparation, distribution, and sale of therapeutic serums. According to this law, attenuated viruses, therapeutic serums, modified toxins, and analogous products, of use in the prophylaxis and treatment of contagious diseases, as well as substances of organic origin for injection, of undefined chemical constitution, for use in the treatment of either acute or chronic affections, shall not be issued, either gratuitously or for payment, without first obtaining the Government authorisation granted on the recommendation of the consultative committee of public hygiene of France and of the Academy of Medicine. The penalty is three months' imprisonment and 50 francs fine. The Court of Cassation has recently handed down a judgment which will cause much consternation in medical circles. A medical man, Dr. Lorot, was prosecuted last year before the Correctional Tribunal of the Seine, under circumstances that gave rise to the question whether the law applied in the case of a medical man who himself injected into his own patients an antituberculous serum of his own discovery and preparation, without first obtaining the required Government authorisation. The tribunal acquitted him, holding that there had not been any issue of the serum. On appeal by the Procureur Général the case was taken into the courts, but the Chamber of Correctional Appeals confirmed the decision of the previous judges. The Procureur Général, however, carried the case to the Criminal Chamber of the Court of Cassation, which quashed the decree of the Chamber of Correctional Appeals that had acquitted Dr. Lorot. It follows from this judgment that a medical man cannot, under penalty of the law, inject his own patients with a serum of his own manufacture without first obtaining the Government authorisation. The Criminal Chamber will determine later the court before which Dr. Lorot is to be brought.

Sept. 4th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

The Report of the Canadian Commission of Conservation for 1910.

THE reports of agricultural surveyors of Canada for 1910 to the Commission of Conservation, which have now appeared, have many interesting medical points in them. In Prince Edward Island 97 per cent. of the inhabitants obtain their water-supply from wells, but no typhoid fever has been reported from any of the farms on the island during the past ten years. In Nova Scotia 74 per cent. of the inhabitants depend on wells and 21 per cent. on springs. In the same period 2 per cent. of the farms have reported typhoid fever. In New Brunswick 60 per cent. depend on wells and 35 per cent. on springs, while typhoid fever appeared on no fewer than 11 per cent. of the farms. According to the report this large percentage of disease goes to show great carelessness regarding the water-supply and the sanitary conditions of the farmhouses and premises. In the English-speaking part of the Province of Quebec 100 per cent. depend on wells, many of them poorly protected, and 5 per cent. of the farms have reported typhoid fever. In the French-speaking part of Quebec the water-supply is furnished by rivers, pipe lines, springs, and wells; 13 per cent. of the farms have reported typhoid fever. In Manitoba 100 per cent. depend on wells, and 6 per cent. of the farms have reported typhoid fever. In Saskatchewan over 80 per cent. depend on wells, and 7 per cent. of the farms have reported typhoid fever. In Alberta 90 per cent. depend on wells, but no cases of typhoid fever have been reported. In British Columbia about 40 per cent. of the inhabitants depend on wells, and 3 per cent. of the farms have reported typhoid fever. The reports also show that with regard to coal mine accidents fatalities therefrom are considerably higher in the United States and in Canada than in any other country of the world for which accurate statistics are available. Furthermore, the fatalities in the United States and in Canada are on the increase, while Great Britain, Belgium, Russia, and France show a gradual decrease. This state of affairs is thus commented on in the report: 1. The danger inherent in the work can never be entirely eliminated, but may be brought down to a minimum, as indicated by the low, constant death-rate in Belgium, Great Britain, and France. 2. Coal explosions occur very frequently in Canada and the United States, while they are more infrequent in other countries. It is not reasonable to expect that the loss of life and property can be entirely done away with, but at the same time experience has abundantly proved that careful and impartial investigations of such conditions will point the way to the remedying of at least some of the abuses.

Ottawa Typhoid Fever Epidemic.

An official report has appeared on the epidemic of typhoid fever which occurred in the city of Ottawa during the early spring of this year. By a process of elimination, milk, food-supplies, insanitary conditions, sewage, flies, and dust were excluded as primary causative factors, and consequently the only other common factor, water, remained. The immediate cause of the epidemic, which began in Ottawa on Jan. 1st, 1911, according to the report, was infection of the water-supply. The pollution of the water-supply began at about the middle of December, 1910, and was mainly due to the unusual lowness of the river and the freezing of the shallow places to the bottom, thus diverting the currents of polluting matter into the sources of public water-supply. The outbreak of the epidemic is now attributed to carelessness on the part of those responsible for the supervision of the water-supply of the city, who, firstly, allowed an old acqueduct to be converted into a sewer, and, secondly, neglected to follow the recommendation, made in October,

that the drinking-water of Ottawa should be subjected to treatment by hypochlorite of lime. The continuance and spread of the epidemic appear to have been due to various obvious causes, such as contact with persons ill of the disease and defective plumbing. Several points of interest were brought out in the investigation by the committee, for instance, that slums and insanitary conditions existed in Ottawa to an extent hitherto unthought of. The great lesson, however, to be learned from the typhoid outbreaks in Montreal, Toronto, Ottawa, and in other parts of Canada is that the only sure mode of protecting the public against the attacks of water-borne diseases is by the installation of an effective filtration system with, what is more important, the provision of adequate storage.

August 30th.

NOTES FROM SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

The Retirement of Government Health Officers.

THE proposal of the Government to retire Dr. A. John Gregory, the medical officer of health for Cape Colony, and Dr. G. Pratt Yule, the medical officer of health for the Orange Free State, was alluded to recently in THE LANCET.[1] It is now officially stated that the Government also proposes to retire Dr. E. Hill, the medical officer of health for Natal. This will leave only two comparatively junior Government health officers on the active list for duty in South Africa, and obviously this staff will be hopelessly inadequate. The decision of the Government, particularly in regard to Dr. Gregory, has provoked the utmost indignation throughout South Africa, and strong resolutions protesting against the proposal of the Government to retire Dr. Gregory have been passed by numbers of professional, municipal, and other public bodies. On July 7th, for instance, the subject was brought forward specially at the Western Cape Branch of the British Medical Association. At this meeting Mr. H. A. Moffat, in moving resolutions dealing with the matter, reviewed briefly the history of the agitation by the profession since the Union for the creation of a department of public health with a medical officer as its administrative head. He pointed out that there was one, and only one, obviously suitable man in South Africa to fill such a post—namely, Dr. Gregory. His length of service, great experience as an organiser and administrator, singled him out above all others. His claims were best shown by the history of public health administration in Cape Colony. There had been a gradual recognition of the importance of its administration, and there had been a gradual increase in powers accorded to the medical officer of health, until in 1907 a definite department had been created with Dr. Gregory as its administrative head. Dr. Gregory, during the whole 20 years of his service, had fought for the best form of public health administration and had finally gained it for the people of Cape Colony. The creation of the department in the Cape was the most eloquent tribute to Dr. Gregory as an organiser and administrator. He had successfully overcome the deep-rooted prejudice of Ministers, and had shown that a medical man could be entrusted with administrative duties. Dr. Gregory was a strong man and he had not chosen the paths of least resistance which would have brought him popularity. Instead he had pursued undeviatingly what he considered best for the country. Dr. A. Jasper Anderson, medical officer of health for Cape Town, in seconding the resolution, pointed out the arduous work Dr. Gregory had had to do as a pioneer in public health. He had been the first Government medical officer of health in South Africa. His had been a most difficult post to fill—one which had brought him into opposition to all sorts of vested interests and prejudices. Dr. Gregory's signal devotion to duty had always been most striking, and he had earned the gratitude and respect of all local authoritiees throughout the Province. Dr. Anderson supported the resolutions in their entirety because it was detrimental to the public interest to retrench an officer of such ripe experience and ability. Dr. Hewat, the president, expressed his accord with the resolutions, for he felt that it was impossible to find another man with the same practical knowledge of conditions in South Africa and of what was not merely theoretically desirable but of what was actually possible. He regarded Dr. Gregory's retirement, at an age when he was at his best and when his service would have been invaluable, as an immense loss to the State. A number of other members also spoke in a similar strain, and the following resolutions were then put and carried unanimously:—

1. This association learns with deep regret that the services of Dr. Gregory are to be dispensed with by the Union Government, and desires to record its sense of the signal value of Dr. Gregory's services as medical officer of health for the Cape Colony, and its appreciation of his devoted energy, integrity, courage, and ability in that capacity.
2. That the Association wishes to voice its convictions that in the organisation of the Public Health Department of the Union the services of Dr. Gregory, an officer of unrivalled experience and tried qualities, should have been retained to direct such organisation.
3. This Association is greatly concerned that the medical officer of health for the Union has not yet been appointed, as such appointment was definitely promised in Parliament by the Minister for the Interior.

It was also resolved that a copy of these resolutions, which are similar to those passed by other branches of the British Medical Association, should be forwarded to the Governor-General in Council, each Member of the Cabinet, the Executive Committee of the Province, the Council of every Municipality throughout the Union, the press, and Dr. Gregory. The Medical Council of the Cape, which is vested with certain advisory functions in regard to public health by statute, at its meeting on July 4th expressed itself in even stronger terms, for the following resolution was then passed:—

That this council deeply regrets the loss of Dr. A. John Gregory, one of its most valuable members, and takes this opportunity of expressing its grateful appreciation of the services rendered by him to it during his 11 years of membership. At the same time this council wishes to protest strongly against the failure of Government to recognise and retain for the Union the unrivalled knowledge and experience gained by Dr. Gregory during nearly 20 years of devoted service, and would further point out that the way in which the health department has been abolished and its head got rid of is contrary to the interests of the country and fraught with grave danger. That this be sent to the Minister for the Interior, the Acting Prime Minister, the Administrator and Council of the Cape Province, and to Dr. Gregory.

Discontent in the Profession.

As a result of the retirement of the three medical officers of health, there is grave discontent in professional circles with the Government. Medical men in other branches of the civil service appear to be realising that the State no longer offers security of tenure to its servants, and there may be difficulty in the securing of good men to fill posts as they fall vacant. Already several subordinate medical officials have handed in their resignations, and it is stated that others will follow suit as opportunity for other employment offers. Amongst those leaving the service shortly may be mentioned Dr. J. C. Mitchell, Government bacteriologist and pathologist for the Transvaal, who has secured the appointment of medical superintendent of the Transvaal Miners' Phthisis Sanatorium at Springkell. The general feeling of discontent has been still further accentuated by the manner in which the patronage of Ministers has been used in the filling of vacant district surgeoncies and other appointments of a similar character.

The Transmission of Leprosy.

The last International Conference on Leprosy held at Bergen suggested that leprosy might possibly be spread by the biting of insects. In a recent issue of the *South African Medical Record* appeared two papers on this subject by Mr. E. C. Long, principal medical officer, Basutoland, and Dr. T. L. L. Sandes, research medical officer, Robben Island. They have apparently been working independently of each other, and both show that bugs fed on the leprous nodules of patients contain in a fair proportion of cases, when killed and the alimentary tracts and contents are examined, bacilli which in shape, size, and staining reactions are similar to the bacillus lepræ. Dr. Sandes states that on May 2nd last he fed some bugs on a case of tubercular leprosy suffering from an acute exacerbation of the disease. On the 15th they were again fed on the same patient. Next morning one of them was found dead. In a smear made from the stomach contents there were a few bacilli, but in smears made from the body tissues field after field displayed numerous acid-fast bacilli. The appearance of these differed, in Dr. Sandes's opinion, from the classic lepra organisms. He states that they were shorter, and some almost coccoid; also that they were more homogeneous in staining, displayed no granularity, had occasionally a median

[1] THE LANCET, August 12th, p. 481.

constriction, and occasionally a terminal clubbing. The great majority were arranged in groups, the individuals in the groups showing a tendency to adhere in parallel formations. Dr. Sandes considered these to be young lepra bacilli in full prolific activity, not having as yet assumed the senile or degenerative forms usually observed in the impacted bacillary masses of human tissues. Dr. Sandes on comparing the organisms from this bug with those from cultures believes them to be identical.

South African Scurvy.

For some years past many practitioners have held the view that "scurvy" as met with in South Africa is different from the disease as met with elsewhere. For instance, it does not appear to follow deprivation of any special article of diet, is not quickly curable, and it appears to have a distinct seasonal variation. Years ago Dr. A. J. Gregory stated his belief that the disease was infectious, and that either the etiology of scurvy has been misunderstood or that the disease if not scurvy is an unrecognised disease simulating scurvy. In recent numbers of the *Transvaal Medical Journal* a lengthy article has appeared from the pen of Dr. W. Morton Hewetson, medical officer to the Wankie Colliery Company, Southern Rhodesia, entitled "The Etiology of Scurvy," which has attracted considerable attention. It would, however, appear very doubtful whether the author is describing the disease regarded elsewhere in South Africa as scurvy. It would seem rather to be pyorrhœa alveolaris, which is very common amongst native labourers. This is a disease, associated often with scurvy it is true, which is mildly infectious, occurs at certain seasons of the year, is unaffected by alterations in diet, is usually unaccompanied by other symptoms, and is readily cured by local treatment. Although Dr. Hewetson's paper has come in for considerable criticism at the hands of the profession, it is possible that the pyorrhœa alveolaris as met with in the compounds may be an early symptom of so-called "scurvy," and one would like to see research work undertaken from a bacteriological standpoint. There is no doubt that diet does play an important rôle in the causation of both conditions, but it is not an important factor in the cure of local inflammation of the gums. It is, however, a factor of great importance in the cure of South African "scurvy." The infectiousness of "scurvy" is now being more and more recognised. For instance, several district surgeons, on a prisoner being admitted to gaol with symptoms of "scurvy," insist on his isolation if possible, and if this cannot be done they prepare themselves for an outbreak of the disease.

Illicit Liquor Trading.

In spite of drastic legislation, the illicit selling of liquor to natives is on the increase, particularly on the Rand and in other mining areas. The traffic is causing much anxiety to those interested in the welfare of the native races of South Africa. It is not as though a sound liquor is supplied; on the contrary, most of that confiscated from time to time by the police is found to be a vile compound, of which "dop" brandy is the principal constituent. It is usually faked with Cape sherry and often fortified with rectified or even methylated spirit. It is often flavoured with bluestone, tobacco, or other deleterious substances. The effect of drinking such a liquor may be imagined. It is disastrous morally and physically; it is responsible undoubtedly for much of the crime on the Rand and elsewhere, and for much of the ill-health amongst native mine-workers, for which the former place particularly has become notorious. The profits are so enormous that the traffic is never likely to be suppressed under present conditions. There are some thinking men who hold that reasonable facilities should be afforded natives for obtaining pure liquors under official observation and regulation. Public opinion would not, however, tolerate this, but most practitioners would agree to a measure permitting the manufacture and sale of good kaffir beer. This is a native beverage which is harmless if not fortified by the addition of spirit. It is, moreover, an excellent anti-scorbutic. If the sale of this article of drink were legalised, and the existing laws relating to the sale of other liquors remained in force, the traffic in "fire-water" would be greatly diminished, if not entirely suppressed. The existing state of affairs demands rectification, but it is doubtful whether the problem will ever be tackled properly by the Government owing to the risk of alienating adherents with temperance sympathies.

Transfer of a Well-known Official.

Mr. Leonard Bostock, the well-known authority on malaria, who contributed a valuable chapter on the subject as relating to the Transvaal, in Sir Ronald Ross's latest book, "The Prevention of Malaria," has resigned his appointments as railway medical officer and district surgeon at Komatie Poort in the Transvaal, and has left to take up an appointment at Porto Amelia in Portuguese Nyassaland. Mr. Bostock has done much good anti-malarial work in the Transvaal, and the Portuguese authorities are to be congratulated on securing his services.

July 25th.

Obituary.

LEONARD CANE, M.D., B.S. LOND., M.R.C.S. ENG., L.S.A.,

CONSULTING PHYSICIAN TO THE PETERBOROUGH INFIRMARY.

Leonard Cane was born at Chichester on July 31st, 1848. He came of a professional stock, no fewer than 24 of his near relatives having been members of the medical profession. After leaving school he became a pupil of his uncle, Dr. Leonard Buckell of Chichester, with whom he lived for five years. During that time he matriculated at the University of London and passed the Preliminary Scientific Examination. In October, 1867, he entered upon his professional studies at University College, London, where he obtained the Atkinson Morley scholarship (£135), the Liston gold medal for clinical surgery, the gold medal for medicine, silver medals for clinical medicine, anatomy and physiology, and other distinctions. At University College Hospital he studied under the eminent men then connected with it, notably Sir William Jenner, Sir J. E. Erichsen, Sir J. Russell Reynolds, and Sir Henry Thompson, and had as fellow students and friends many who have since risen to great eminence in their profession, amongst whom may be mentioned Sir Thomas Barlow and Sir John Tweedy. Dr. Cane took the degree of M.B., B.S. Lond. in 1872, graduating with honours in both. He took the degree of M.D. Lond. in 1873, and held also the diplomas of M.R.C.S. Eng. and L.S.A. In 1875 he went into partnership with Mr. Thomas Southam of Peterborough, an old-established practitioner of that city. Here he succeeded in making a large general practice, and held several public appointments. In 1876 he was elected consulting surgeon to the Peterborough Infirmary, and in 1895 he was elected physician, which post he held until 1906, when he was compelled by paralysis agitans to retire from practice. He then went to reside at Eastbourne where he had built a house at the foot of the Downs.

Dr. Cane had three sons and one daughter. The eldest son, who took his M.D. degree at Cambridge a few months before his father's death, succeeded him in the practice at Peterborough and was appointed assistant physician to the infirmary. The second son joined the Royal Army Medical Corps, and the third son is also entering the profession. Here, indeed, is a family in whom the hereditary instinct for medicine, to which we alluded in these columns recently as becoming less pronounced, is extraordinarily in evidence. But that so first-class a practitioner of our science and art as he whose death we are now recording should have been closely followed by his children is not perhaps extraordinary, for as well as the example of a father they had that of a brilliant expositor always before them.

ARTHUR BEADLES, M.R.C.S. ENG., L.S.A.

THE death is announced of Mr. Arthur Beadles of Forest Hill, who died at Dover on August 19th. He was the son of John Nathaniel Beadles, who practised as a medical man at Broadway, Worcestershire. Arthur Beadles was educated at Irving's School, Mitcheldean, Gloucestershire, and in 1856 was apprenticed to his father in accordance with the usual routine of the day. After four years of this practical training he entered the medical school at Westminster Hospital, and obtained his diplomas in 1862 and 1863. After holding office as house surgeon at the Westminster Hospital, in 1866 he settled at Forest Hill, and there for many years he was one of the hardest worked of men in a large practice which he made

for himself. His powers of observation and his common-sense gave him a breadth of view and a grasp of many of the problems of clinical medicine that rightly inspired confidence in the public. For many years he was frequently hampered by recurrent attacks of rheumatic iritis. These were attended with gradual impairment of sight, which at last compelled his complete retirement in 1907 to Dover, where he died on August 19th. He was buried hard by the scene of his life's work at Elmer's End on August 23rd.

Dr. Eustace Smith sends us the following personal appreciation:—"Mr. Arthur Beadles was for many years the principal practitioner at Forest Hill, where his abilities and professional skill were universally recognised and esteemed. He was one of the old school of family physicians who brought a large fund of common-sense to bear upon his treatment, and whose intimate knowledge of drugs and their uses enabled him to treat the ailments and diseases of his patients with a readiness of resource and a success which commanded at once their gratitude and admiration. Mr. Beadles was in practice for many years before the days of microbes, but he was careful, in spite of his many engagements, to keep himself abreast of the advances of medical science, although he was never led by the allurements of the microscope or the charms of bacteriological research to forget that the primary object of his calling was the alleviation of suffering, to which his life was devoted. His amiable disposition and kindness of heart endeared him to all who had the privilege of his friendship, and his intellectual gifts and keen interest in literature and the arts made him a welcome companion. His loss will be felt by many besides the members of his own family."

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Jonas Baron, professor of surgery in Budapest. Dr. Felici Filippo, *privat docent* of medical pathology in the University of Rome. Dr. T. Place, formerly professor of physiology in the University of Amsterdam. Dr. P. Girot, professor of natural history in the Clermont Medical School. Dr. L. Bruandet, professor of anatomy in the Rheims Medical School.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Külbs of Kiel has been recognised as *privat-docent* of Medicine.—*Bologna:* Dr. Teresio Rezzia has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Gratz:* Dr. Paul Mathies, *privat-docent* of midwifery, and Dr. Hans Spitzy, *privat-docent* of orthopædic surgery, have been granted the title of Extraordinary Professor.—*Heidelberg:* Dr. Tobler, *privat-docent* of pædiatry, has been granted the title of Extraordinary Professor. Dr. August Homburger has been recognised as *privat-docent* of Psychiatry.—*Innsbruck:* Dr. W. Trendelenburg of Freiburg has been appointed to the chair of Physiology in succession to Dr. F. Hofmann.—*Lemberg:* Dr. Paul Kucera, Extraordinary Professor of Hygiene, has been promoted to the Ordinary Professorship.—*Marseilles:* Dr. Olmer has been appointed Professor of Hygiene and Forensic Medicine in succession to the late Dr. Fallot.—*New York (College of Physicians and Surgeons):* Dr. Horatio B. Williams has been appointed Adjunct Professor of Medical Entomology.—*Prague (German University):* Dr. Hermann Schloffer of Innsbruck has been appointed to the chair of Surgery in succession to Dr. Wölfler.—*Rome:* Dr. Arsenio Brugnola of Sarsari has been recognised as *privat-docent* of Medical Pathology.—*San Francisco (University of California):* Dr. J. G. Fitzgerald has been appointed Adjunct Professor of Bacteriology.—*Sienna:* Dr. Luigi Rugani of Turin has been recognised as *privat-docent* of Laryngology and Otology.—*Tübingen:* Dr. A. Basler, *privat-docent* of Physiology, has been granted the title of Extraordinary Professor.

LITERARY INTELLIGENCE.—Messrs. J. and A. Churchill announce the ninth edition of Dr. Frederick Taylor's "Practice of Medicine." The work, which will be in a larger form, has been very thoroughly revised. Considerable alterations and additions have been made in dealing with the subjects of cholera, dysentery, aphasia, hysteria, obstruction of the bronchi, phthisis, the physical examination of the heart and vessels, colitis and appendicitis, ankylostoma, gall-stones, anæmia and leukæmia, diabetes, and functional albuminuria. The subjects new to this edition are pellagra, meralgia pariæsthetica, pneumococcal meningitis, myotonia congenita, enterospasm, Hirschsprung's disease, intermittent claudication, congenital family cholæmia, peritoneal adhesions, lymphatism, bacilluria, and pneumaturia. The illustrations in the text have been increased.—Mr. William Heinemann of Bedford-street, Strand, will in the autumn publish a work by Dr. Nansen, entitled "Through Northern Mists," in two quarto volumes; it will be illustrated from old charts and engravings, as well as from drawings by the author. The same publisher also announces, under the title of the "Modern Criminal Science Series," translations of some of the most interesting volumes by continental writers on different phases of crime and criminality. The first four to appear will be: "Criminal Psychology," by Hans Gross; "Modern Theories of Criminality," by C. Bernaldo de Quiros; "Crime: its Cause and Remedies," by Cesare Lombroso; and "Criminal Sociology," by Enrico Ferri.

THE THIRD CONGRESS OF THE INTERNATIONAL SOCIETY OF SURGERY.—The following is the programme of the Third Congress of the International Society of Surgery, which will take place this month at Brussels:—Sept. 25th: 2.30 P.M., Meeting of the International Committee. 8 P.M., Reception to the members of the Congress by Professor Dr. Lorthioir, President of the Belgian Society of Surgery. Sept. 26th: 9.30 A.M., Formal opening of the Congress; opening of the Exhibitions of Fractures and of Surgical Apparatus. 10.30 A.M., The Diagnosis of Pancreatitis, by Professor Dr. Gaston Michel of Nancy. 2 P.M., The Treatment of Pancreatitis, by Professor Dr. W. Körte of Berlin and M. Giordano. 9 P.M., Reception to the members of the Congress by Professor Lucas-Championnière, President of the International Society of Surgery. Sept. 27th: 9 A.M., Pneumothorax, Ways and Modes of Access; Emphysema, by M. Garré of Bonn; Acute Purulent Pleurisy, by Professor Dr. H. Gaudier of Lille; Pleural Fistulæ, by M. Girard. 2 P.M., Pleuro-pulmonary Wounds, by Professor Ch. Lenormant; Pulmonary Tumours and Parasites, by Professor A. H. Ferguson of Chicago. Sept. 28th: 9 A.M., Demonstrations of the Treatment of Fractures. 2 P.M., General meeting. 3 P.M., Pleuro-pulmonary Abscess and Gangrene, by M. Van Stockum; Bronchiectasia, by Professor Sauerbach of Zürich. 7.30 P.M., Banquet. Sept. 29th: 8 A.M., The Surgical Treatment of Pulmonary Tuberculosis, by M. P. L. Friedrich of Marburg. 10 A.M., Acute Colitis, by Professor E. Sonnenburg of Berlin. 3 P.M., Chronic Colitis, by M. Ségond, Dr. C. L. Gibson of New York, Mr. D'Arcy Power of London. Discussions will take place on all the papers. 8 P.M., Special performance at the Théâtre Royal de la Monnaie.

THE BRITISH HOSPITALS ASSOCIATION.—The second annual conference of this association, whose object is to promote the discussion of matters connected with hospital management and to give opportunities for the acquisition of a knowledge of hospital administration, will be held in Manchester on Thursday and Friday, Sept. 28th and 29th. The first day will be devoted to a discussion on the National Insurance Bill and its probable effects upon the voluntary hospitals, in which the following are expected to take part: Sir William Cobbett, chairman, Royal Infirmary, Manchester; Mr. Charles Lupton, chairman, General Infirmary, Leeds; Dr. D. J. Mackintosh, M.V.O., superintendent, Western Infirmary, Glasgow; and Mr. Howard J. Collins, house governor, General Hospital, Birmingham. On Friday papers will be read as follows: (1) Representation of Honorary Medical Staffs upon Boards of Management of Voluntary Hospitals, by Dr. E. S. Reynolds, chairman of the medical board, Manchester Royal Infirmary; and (2) The Methods of Distribution of Hospital Saturday and Sunday Funds, by Mr. Charles Hopkinson, member of the board, Manchester Royal Infirmary. The meetings of the conference will open each day at 10 A.M. in the Lord Mayor's parlour at the Town Hall. Members of the association will be entertained at luncheon each day by the United Hospitals of Manchester, and the Lord Mayor will hold a reception on the afternoon of the first day, while visits of inspection to the various local

hospitals will be arranged. The honorary local secretary is Mr. W. G. Carnt, Royal Infirmary, Manchester. Trustees, members of committees or executive, and professional heads of hospitals and kindred institutions are eligible for membership. Application should be made to Mr. Conrad W. Thies, Royal Free Hospital, London, W.C., the honorary treasurer.

PRESENTATION TO A MEDICAL PRACTITIONER.—Dr. R. F. Gill of King Henry's-road, South Hampstead, who recently retired from active work owing to ill-health, has been presented by his former patients and friends with a cheque for £120 and other gifts as a mark of their esteem.

LONGEVITY.—Mrs. Drew, of Arden Caple House, near Helensburgh, Dumbartonshire, celebrated the anniversary of her hundredth birthday on August 1st, and received a letter of congratulation on behalf of the King. In 1829 Mrs. Drew met and conversed with Sir Walter Scott in her aunt's house at Orbiston, Lanarkshire.

Dr. Halls Dally, whose paper on Pachon's Sphygmo-oscillometer was published in THE LANCET last week, wishes to remedy an oversight in his work. He omitted by accident to refer to a communication on the estimate of blood pressure by means of the sphygmo-oscillometer which was published in the *British Medical Journal* of Dec. 3rd, 1910.

NOTIFICATION OF ACUTE POLIOMYELITIS.—The London County Council has made an Order that in the Administrative County of London, Section 55 of the Public Health (London) Act, 1891, with respect to the notification of infectious diseases, shall apply to acute poliomyelitis or acute polio-encephalitis. The Order, which has been approved by the Local Government Board, came into operation on Sept. 1st, and will continue in force until March 12th, 1912.

THE SOUTHWARK MORTUARY.—At the Southwark coroner's court, on August 30th, Dr. F. J. Waldo again called attention to the necessity for new mortuary accommodation in the district, and said that perhaps an alteration would be made owing to the publicity which had been given to the matter from time to time. If an improvement was made, he thought it would be better for the health of the district, the death-rate of which had been very high. Dr. Waldo further mentioned that every time he called a jury, half an hour or more was wasted owing to the distance of the mortuary from the court. A jury had recently complained that the children in the churchyard playground adjacent to the mortuary were distressed by the foul emanations proceeding from the mortuary. Medical men also objected to making necropsies in such an atmosphere.

LONDON INTER-COLLEGIATE SCHOLARSHIPS BOARD: MEDICAL SCHOLARSHIPS AND EXHIBITIONS.—In addition to the scholarships previously advertised, two scholarships in arts and science and two scholarships in anatomy and physiology, tenable at Charing Cross Hospital Medical School, will be offered for competition at the September examination of the London Inter-Collegiate Scholarships Board. On the results of this examination, therefore, elections will be made to 32 entrance medical scholarships, tenable at the following schools of the University of London: University College, King's College, Westminster Hospital, St. George's Hospital, Charing Cross Hospital, London School of Medicine for Women, University College Hospital, and King's College Hospital. Further information may be obtained from the deans of the respective medical schools, or from the secretary of the board, Mr. Alfred E. G. Attoe, University of London, University College (Gower-street, London, W.C.).

BOOKS, ETC., RECEIVED.

UNIONE TIPOGRAFICO-EDITRICE TORINESE, Torino (Corso Raffaello, 28), Milano, Roma, Napoli.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

FORDE, ROBERT MICHAEL, L.R.C.P. & S. Edin. (Principal Medical Officer), has been appointed an Official Member of the Legislative Council of the Colony of Sierra Leone.

HOLMES, PATRICK JOHN, L.R.C.P. & S. Irel., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Killaloe District of the county of Clare.

KIRK, THOMAS DICK, M.D., M.Ch. R.U.I., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Montgomery District of the counties of Montgomery and Salop.

MATHIESON, D. MORLEY, M.D. Edin., D.P.H., has been appointed Medical Officer of Health and Medical Superintendent of the Infectious Diseases Hospitals for the County Borough of South Shields.

MOXON, HERBERT W., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Matlock District of the county of Derby.

WHELAN, JOHN B. B., M.D. Dub., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Ruskington District of the county of Lincoln.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ASHTON-UNDER-LYNE, DISTRICT INFIRMARY AND CHILDREN'S HOSPITAL.—Senior House Surgeon. Salary £120 per annum, with board, residence, and laundry.

AYR DISTRICT ASYLUM.—Junior Assistant Medical Officer. Salary £120 per annum, with board, lodging, and laundry.

BANGOR, CARNARVONSHIRE AND ANGLESEY INFIRMARY.—House Surgeon. Salary £100 per annum, with board, washing, and lodging.

BIRMINGHAM GENERAL HOSPITAL.—Dental Surgeon. Salary £50 per annum.

BODMIN, CORNWALL COUNTY ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £140 per annum, with rooms, rations, laundry, and attendance.

BRADFORD ROYAL INFIRMARY.—House Physician, unmarried. Salary £100 per annum, with board, residence, and washing.

BRECKNOCK COUNTY AND BOROUGH INFIRMARY.—Resident House Surgeon, unmarried. Salary £120 per annum, with apartments, board, attendance, &c.

BRIGHTON AND HOVE HOSPITAL FOR WOMEN.—House Surgeon, unmarried, for six months. Salary £80 per annum, with apartments, board, attendance, &c.

BRISTOL ROYAL INFIRMARY.—Resident Casualty Officer for six months. Salary at rate of £50 per annum, with board, lodging, and washing. Also House Surgeon. Salary £100 per annum, with apartments, board, and laundry.

CANCER HOSPITAL, Fulham-road, London, S.W.—House Surgeon for six months. Salary £70 per annum.

CARLISLE DISPENSARY.—Resident Medical Officer. Salary £150 per annum, with apartments.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn-road, W.C.—House Surgeon. Salary at rate of £50 per annum, with board and residence.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—House Physician. Salary £70 per annum, with board, apartments, and laundry.

COLCHESTER, ESSEX COUNTY HOSPITAL.—House Surgeon. Salary £80 per annum, with board, washing, and residence.

CROSSLEY SANATORIUM, Delamere Forest, Cheshire.—Assistant Medical Officer. Salary £100 per annum, with board, apartments, and laundry.

DEVONPORT, ROYAL ALBERT HOSPITAL.—House Surgeon, unmarried. Salary £125 per annum. Also Assistant House Surgeon, unmarried, for six months. Salary at rate of £75 per annum. With board, apartments, laundry, &c., in each case.

DUDLEY, GUEST HOSPITAL.—Assistant House Surgeon for six months. Salary £75 per annum, with residence, board, and washing.

DUNFERMLINE, CARNEGIE DUNFERMLINE TRUST.—Assistant Medical Officer. Salary at rate of £250 per annum.

EALING, KING EDWARD MEMORIAL HOSPITAL.—House Surgeon, unmarried, for six months. Salary at rate of £80 per annum, with board, apartments, and laundry.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—House Physician and House Surgeon. Salary in each case at rate of £75 per annum, with board, residence, and laundry.

EDINBURGH SCHOOL BOARD.—Assistant Medical Officer. Salary at rate of £250 per annum.

EXETER, ROYAL DEVON AND EXETER HOSPITAL.—House Physician and Assistant House Surgeon for six months. Salary at rate of £60 per annum, with board, apartments, and washing.

GLOUCESTER, GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board, residence, and washing.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N.—Resident Medical Officer. Salary £120 per annum, with board, lodging, and laundry.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—Assistant House Surgeon. Salary £75 per annum, with board, residence, and laundry.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.—House Physician for six months. Salary at rate of £70 per annum, with board and residence.

HASTINGS, EAST SUSSEX HOSPITAL.—Senior House Surgeon. Salary £100 per annum, with residence, board, and washing. Also Assistant House Surgeon. Salary at rate of £50 per annum with residence, board, and washing.

HEMEL HEMPSTEAD, HERTS, WEST HERTS HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with rooms, board, and washing.

HOLBORN UNION INFIRMARY, Archway-road, Upper Holloway, N.—Second Assistant Medical Officer. Salary £80 per annum, with board, apartments, and washing.

LEAMINGTON SPA, WARNEFORD, LEAMINGTON, AND SOUTH WARWICKSHIRE GENERAL HOSPITAL.—House Surgeon. Salary £100 per annum, with residence, board, and laundry.

LEEDS PUBLIC DISPENSARY.—Junior Resident Medical Officer. Salary £100 per annum, with board, residence, and washing.

LEICESTER BOROUGH LUNATIC ASYLUM.—Medical Superintendent. Salary £800 per annum.

LEICESTER INFIRMARY.—House Physician. Salary at rate of £100 per annum, with board, lodging, and washing.

LEITH HOSPITAL.—Out-door Visiting Physician for six months. Salary at rate of £100 per annum, with board.

LEWES DISPENSARY AND INFIRMARY AND VICTORIA HOSPITAL.—Resident Medical Officer. Salary £120 per annum, with apartments, board, washing, attendance, &c.

LIVERPOOL DISPENSARIES.—Head Surgeon, unmarried. Salary £170 per annum, with board and apartments. Also Assistant Surgeon, unmarried. Salary £100 per annum, with board and apartments.

LIVERPOOL INFECTIOUS DISEASES HOSPITAL.—Assistant Resident Medical Officer, unmarried. Salary £120 per annum, with board, washing, and lodging.

LONDON COUNTY COUNCIL.—Medical Officer of Health of the County of London. Salary £1250 a year and travelling expenses.

MARGARET-STREET HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, 26, Margaret-street, W.—Honorary Physician. Also Honorary Dental Surgeon.

MIDDLESBROUGH, NORTH RIDING INFIRMARY.—Assistant House Surgeon for six months. Salary £75 per annum, with residence, board, and washing.

MILLER GENERAL HOSPITAL FOR SOUTH-EAST LONDON, Greenwich road, S.E.—Senior and Junior House Surgeon, each for six months. Salaries at rate of £100 and £80 per annum respectively, with apartments, board, attendance, and laundry.

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon, unmarried. Salary £160 per annum, with apartments, attendance, &c.

NOTTINGHAM GENERAL HOSPITAL.—Assistant House Surgeon. Salary £100 per annum, with board, lodging, and washing.

PETERBOROUGH INFIRMARY.—House Surgeon, unmarried. Salary £100 per annum, with residence, board, and laundry.

PRESCOT UNION WORKHOUSE AND INFIRMARY, Whiston.—Resident Assistant Medical Officer, unmarried. Salary £120 per annum, with apartments, board, washing, &c.

PRESTON ROYAL INFIRMARY.—Senior House Surgeon, unmarried, for six months. Salary £80 per annum, with board, residence, and washing.

PRETORIA LUNATIC ASYLUM.—Junior Medical Officer. Salary £360 per annum, with quarters, rations, fuel, light, washing, and attendance.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Resident Medical Officer for four months. Salary at rate of £60 per annum, with board, residence, and washing.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, N.E.—House Surgeon for six months. Salary at rate of £80 per annum, with board, residence, and washing.

RAROTONGA, COOK ISLANDS.—Assistant Medical Officer. Salary £350 per annum.

ROCHDALE INFIRMARY.—Senior House Surgeon, unmarried. Salary £100 per annum, with board, residence, and laundry.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—House Physician for six months. Salary at rate of £60 per annum, with board, lodging, and washing.

ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C.—Third House Surgeon. Salary at rate of £50 per annum, with board and residence.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—Resident House Surgeon, unmarried, for six months. Salary £100 per annum, with board, residence, and washing.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.—Honorary Dental Surgeon.

ST. PETER'S HOSPITAL FOR STONE, &c., Henrietta-street, Covent Garden, W.C.—Junior House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone-road, N.W.—Resident House Surgeon. Salary £80 per annum, with board and residence.

STAFFORD, STAFFORDSHIRE COUNTY ASYLUM.—Assistant Medical Officer, unmarried. Salary £150 per annum, with apartments, board, and washing.

STOCKPORT INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, washing, and residence.

STROUD GENERAL HOSPITAL.—House Surgeon. Salary £100 per annum, with board, lodging, and washing.

TAUNTON AND SOMERSET HOSPITAL.—Resident Assistant House Surgeon for six months. Salary at rate of £70 per annum, with board, lodging, and laundry.

WALSALL AND DISTRICT HOSPITAL.—House Physician and Casualty Officer. Salary £80 per annum, with board, residence, and laundry.

WEST HAM AND EASTERN GENERAL HOSPITAL, Stratford, E.—Junior House Physician. Salary £75 per annum.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon for six months. Salary £80 per annum, with board, rooms, and laundry.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Act at Slaithwaite, in the West Riding of Yorkshire.

Births, Marriages, and Deaths.

BIRTHS.

BUTT.—On August 31st, at Randfontein, Transvaal, the wife of H. T. Hayward Butt, M.B., M.R.C.S., L.R.C.P., of a son.

HANSON.—On Sept. 5th, at Frognal, Hampstead, the wife of Reginald John Edward Hanson, F.R.C.S E., of a son.

HEATH.—On August 31st, at Weymouth-street, W., the wife of P. Maynard Heath, M.S., F.R.C.S., of a son.

NIMMO.—On August 7th, at Chakrata, United Provinces, India, the wife of Captain Wilfrid C. Nimmo, R.A.M.C., of a daughter.

PORTER.—On August 29th, at St. James's-road, Surbiton, the wife of George Porter, M.D., of a daughter.

MARRIAGES.

BRUCE—OWEN.—On August 31st, at St. Michael's, Playden, by the Rev. J. Casper Lintott, Harold Wilson Bruce, M.D., to Ethel Madeline, second daughter of the late Frank Owen of Rye.

DICK—DUKE.—On August 30th, at St. Andrew's Church, Muswell Hill, John Lawson Dick, M.D., F.R.C.S., to Norah Winiefred, daughter of the late Captain W. E. Duke.

GOODING—SEEL.—On Sept. 2nd, at the Church of the Holy Innocents, South Norwood, Simonds Gooding, M.D., to Edith May, daughter of Thomas J. Seel.

MORLEY—DIXEY.—On Sept. 1st, at Union Chapel, Islington, Edwin B. Morley, M.B., B.S., to Ada Mary, daughter of Albert Dixey.

ROBERTS—NICHOLSON.—On August 31st, at St. Michael's Church, Hoveringham, Notts, by Rev. J. E. Kent, M.A., Chaplain to Royal Army Medical Corps, Territorial, and Rev. A. M. Y. Bailey, M.A., Vicar, Charles Roberts, F.R.C.S., to Ethel, second daughter of Arthur Nicholson, of Burnside, Hoveringham. At home, Ravensbourne, Victoria Park, Manchester, Oct. 24th, 25th, and 26th.

WARING—RELTON.—On August 29th, at St. John's Cathedral, Hong-Kong, Captain Arthur Durham Waring, R.A.M.C., to Gladys Frances Lyons Relton, daughter of Arthur John Relton.

DEATHS.

CANE.—On Saturday, Sept. 2nd, at St. Oswald's, Meads, Eastbourne, Leonard Cane, M.D., aged 63, late of the Mansion House, Peterborough. Cremated at Golder's Green on Wednesday, Sept. 6th, at 2.30 P.M.

WYNNE.—On Sept. 1st, at Eryl Môr, Newquay, John Kendrick Wynne, M.D.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

HUSTLE.

THE following breathless itinerary was handed to a correspondent of THE LANCET by the cicerone of a party of Americans from the Southern States who were "doing the English lakes" between the evening of one day and the afternoon of the next. The travellers were not unintelligent. Indeed, they were mostly ladies with the courtesy of manner which American writers claim to be peculiar to Georgia and Virginia. This demeanour was in strange contrast to the austere bluffness of the people among whom for a brief spell they found themselves. Naturally they looked excessively tired, and the medical eye discovered among them the traces of dyspepsia and nerve-strain due to accomplishing a tour almost identical with that here printed. The document *donne furieusement à penser* both on psychological and hygienic grounds. It is also an ethnological curiosity.

VISITING ENGLAND, FRANCE, BELGIUM, HOLLAND, GERMANY, AUSTRIA, SWITZERLAND, AND ITALY.

July 22nd, Saturday.—Sail on ss. *Cincinnati* (18,000 tons), Hamburg-American Line ($105.00 berth).

July 31st, August 1st, 2nd, 3rd, 4th, Monday, Tuesday, Wednesday, Thursday, and Friday.—In London.

August 5th, Saturday.—Leave for Paris *viâ* Newhaven-Dieppe, stopping at Rouen.

August 6th, 7th, 8th, 9th.—In Paris (Grand Hotel du Louvre).

August 10th, 11th, 12th, Thursday, Friday, and Saturday.—Motor *viâ* Versailles to Blois, to Orleans, Touraine Country, Fontainebleau, and return to Paris.

August 13th, Sunday.—In Paris.

August 14th, Monday.—To Brussels.

August 15th, Tuesday.—In Brussels (Grand Hotel).

August 16th, Wednesday.—Leave *viâ* Antwerp to the Hague.

August 17th and 18th.—In the Hague and Scheveningen (Hotel Paulez).

August 19th and 20th, Saturday and Sunday.—Amsterdam and Isle of Marken (Hotel Victoria.)

August 21st, Monday.—To Cologne (Hotel Disch).

August 22nd, Tuesday.—Up the Rhine to Mayence (Rheinerscherhof).

August 23rd, Wednesday.—*Viâ* Wiesbaden to Heidelberg.

August 24th, Thursday.—In Heidelberg (Schloss Hotel).

August 25th, Friday.—Leave for Munich.

August 26th, Saturday and Sunday.—In Munich (Hotel Bellevue).

August 29th, Tuesday.—Down Danube to Vienna.

August 30th and 31st, Wednesday and Thursday.—In Vienna (Hotel Metropole).

Sept. 1st, Friday.—To Innsbruck.

Sept. 2nd, Saturday.—To Lucerne.

Sept. 3rd.—In Lucerne (Hotel des Balances).

Sept. 4th, Monday.—Travel *viâ* lake and train to Andermere and coach over Furka Pass to Rhine Glacier (Rhine Glacier Hotel).

Sept. 5th, Tuesday.—Coach 32 miles along the Rhone River to Brieg and train to Zermatt.

Sept. 6th and 7th, Wednesday and Thursday.—In Zermatt (Mont Cervin Hotel).

Sept. 8th, Friday.—Leave *viâ* Visp to Brieg and coach over the famous Simplon Pass to Pallanza along Lake Maggiore (Grand Hotel Pallanza).

Sept. 9th, Saturday.—Italian Lakes to Milan.

Sept. 10th, Sunday.—Morning to Milan and afternoon to Venice.

Sept. 11th, 12th, 13th.—In Venice (Grand Hotel on Grand Canal).

Sept. 14th, Thursday.—To Rome.

Sept. 15th, 16th, 17th, 18th, 19th, 20th.—In Rome (Hotel Michel).

Sept. 21st, Thursday.—To Naples (Grand Hotel Santa Lucia).

Sept. 22nd, 23rd, 24th.—Pompeii, Sorento, Capri, and in Naples.

Sept. 25th, Monday.—To Florence.

Sept. 26th, 27th, 28th, 29th.—In Florence (Grand Hotel de la Ville).

Sept. 30th, Saturday.—*Viâ* Pisa to Genoa.

Oct. 1st, Sunday.—Afternoon to Monte Carlo.

Oct. 2nd, Monday.—Motor over Upper Corniche Road to Nice and train to Marseilles.

Oct. 3rd, Tuesday.—To Paris.

Oct. 4th and 5th.—In Paris.

Oct. 6th.—Sail *viâ* s.s. *Bluecher*, Hamburg-American Line ($90.00 berth).

Oct. 14th.—Due in New York.

HOSPITALS AND CHARITABLE INSTITUTIONS IN URUGUAY.

His Majesty's Minister in the Republic of Uruguay, Mr. R. J. Kennedy, in his annual report, states that the total population is a little over 1,000,000, and includes 1324 British subjects. Only those are returned under this head who were born outside of Uruguay; children born in the country of British subjects are Uruguayans, enjoying all the privileges and liable to all the obligations appertaining to Uruguayan citizenship. In 1886 a National Commission of Charity and Public Benefaction was created as a State institution under the supervision of the Ministry of the Interior. The Hospital of Charity was placed under the management of this Commission, and the property held by it is valued at £570,000; the principal source of revenue, amounting annually to about £270,000, is the profit derived from the sale of State lottery tickets. A charge, fixed periodically by the Commission, is made for admission to the various institutions under its management. Amongst these may be mentioned the Orphans and Foundlings Asylum, the Mendicants and Incurables Asylum, the Lunatic Asylum, the Isolation Hospital for Infectious Diseases, three asylums for children between the ages of 2 and 8 years, and a deaf and dumb institute. The cost of maintenance in these institutions is estimated per month as follows: Monte Video Hospital of Charity, £4 2*s.* *d.*; Mendicants and Incurables Asylum, £1 18*s.* 4*d.*; Orphans and Foundlings Asylum, £2 9*s.* 5*d.*; Lunatic Asylum, £1 8*s.* 6*d.*; Isolation Hospital, £4 12*s.* 4*d.* Besides these institutions there are in Monte Video several private hospitals and nursing homes, and a British, an Italian, and a Spanish hospital; also, all the chief provincial towns are provided with hospitals managed by the local authorities. During the year 1910 617 indoor patients were treated at the British Hospital, and of this number 437 were discharged as cured and 94 as improved.

The British Hospital was founded 22 years ago as a British seamen's hospital, and is probably at the present time the best managed hospital institution in Monte Video. It contains accommodation for about 50 patients, including paying patients who occupy private or semi-private rooms, and it receives sick persons of all nationalities on the recommendation of subscribers, preference being always given to British or North American nationality. The building occupied by the hospital is old and out of date, and for several years this has been impressed upon those interested. A new and up-to-date building in a more suitable place than its present overcrowded locality has been greatly needed, but the difficulty with which the hospital committee (of which the British Minister is *ex-officio* chairman) was confronted was the want of funds. This has now been solved by devoting to the building of a new hospital the subscriptions paid into the King Edward VII. Memorial Fund. Nearly £6000 are thus available, and that sum, together with the estimated value of the old hospital (which is to be sold) and the issue of bonds to the value of £6000 (all taken up privately by friends and well-wishers), will provide the full amount necessary. Plans and estimates have been prepared; the new building will be begun this year, and it will be known as "The British Seamen's and King Edward VII. Memorial Hospital." The generous manner in which many Uruguayan commercial firms subscribed towards this memorial testifies in an eloquent manner to the warmth of Anglo-Uruguayan friendship.

CHILDREN'S COUNTRY HOLIDAYS FUND.

To the Editor of THE LANCET.

SIR,—I venture to ask the hospitality of your columns on behalf of the Children's Country Holidays Fund. The object of the Fund is to send to the country for a fortnight the children of the poorest classes in London. Those of us who are now enjoying our annual holidays are best able to realise what such a fortnight must mean to children whose horizon would otherwise always be bounded by streets and slums, and we venture to appeal for assistance in order to carry out this work.

The expenses of the Fund increase annually, and this year they have been exceptionally heavy, and unless we are able to speedily obtain the sum of £3000 the work of the Fund will have to be seriously curtailed. Subscriptions and donations will be gratefully received and acknowledged by me here.—I am, Sir, yours faithfully,

ARRAN,
Honorary Treasurer, Children's Country Holidays Fund.

18, Buckingham-street, Strand, W.C., August 31st, 1911.

SOME SAMOAN DISEASES.

Mr. T. Trood, Acting British Vice-Consul for Samoa (or Navigator Islands), in his report for 1910 describes a visit to Samoa from Dr. N. Leber, of the Imperial University Hospital for Eye Diseases, Berlin, and Dr. von Provaczek, from the Institute for Ship and Tropical Diseases, Hamburg. These gentlemen investigated the epidemic eye diseases prevalent in Samoa for several years, their main object being to find out the causes as well as the means whereby they can be stamped out. Their visit was a great boon to the islands, for many of the native inhabitants were suffering from eye diseases. Their treatment has been singularly successful, for the Government having brought them out,

they rendered advice gratis to all native patients. The report says further: "Dr. von Provaczek has made experiments regarding the 'hook-worm' disease and other tropical complaints. He has also examined horses suffering from disease peculiar to the climate, and, I am told, strongly recommends the appointment for Samoa of a veterinary surgeon. In Tutuila for many months past the medical gentlemen attached to the Government staff and navy have been combating the 'hook-worm' disease, very prevalent there formerly, with great advantage to the Tutuila residents, foreigners as well as natives."

A WARNING.

To the Editor of THE LANCET.

SIR,—A consulting-room thief is on the warpath, and his method is a variant on some older ones. He is a foreigner—German, I think—speaking English indifferently. He presented a card bearing the name of a Toronto firm (which I forget), and had a slip of paper on which was written the title of an old article of mine. He was anxious to get this and any other useful books and pamphlets, explaining that a large sum of money had been left for the purpose of forming a library. I paid little heed to his incoherent story, and, being anxious to get rid of him, I told him to apply to THE LANCET Office, and left the room for less than a minute to get the date of the article from the Medical Directory. He was profuse in thanks and apologies, and backed himself—and my opera-glasses—out of the house. As my house is a home for nerve cases and bears no professional plate, and is situated in a retired spot, the thief must have had local knowledge.

I am, Sir, yours faithfully,

St. George's-terrace, N.W., Sept. 5th, 1911. J. SCOTT BATTAMS.

*** Dr. Scott Battams has perhaps made the acquaintance of a gentleman against whom the profession was warned in THE LANCET of August 5th, 1911 (p. 419).—ED. L.

"A GATE BEAUTIFUL."

THIS is the title of a sixpenny publication issued from the offices of the Ragged School Union, 32, John-street, Bedford-row, London, W.C. Tens of thousands of children in London are beneficiaries of its activity, which is expended in looking after the health, food, clothing, religious training, physical development, and recreation of the little dwellers in "slum-land," the "drift children." It is profusely illustrated, the pictures giving a good insight into the far-reaching domain of its work. The Ragged School Union was one of the fortunate recipients of a gift, on the apportionment of the King, out of the munificent sum left by the Maharaja of Gwalior for distribution. A picture on the cover shows a boy scout helping along a little cripple.

WEATHER INSTRUMENTS FOR AMATEUR METEOROLOGISTS.

WE have received a sixpenny booklet entitled "Weather Instruments and How to Use Them," by Mr. D. W. Horner, which describes in clear and simple language the meteorological instruments employed at the "second order" stations of the Royal Meteorological Society. It is intended as a companion work to the author's little handbook on "Observing and Forecasting the Weather," and both are published by Witherby and Co., 326, High Holborn, London, W.C. There must be many people who take a mildly scientific interest in the weather, and who would like to know how to set up and read and take care of, or at least how to understand, such common meteorological instruments as the rain gauge, the wet and dry bulb thermometer, the barometer, the sunshine recorder, and the wind gauge. This small work tells them how to do so in a very readable way. Every amateur who reads it will in future study the weather reports in the newspapers with new interest and understanding, and will be able, if he wishes, to make his own meteorological observations and records in a scientific manner.

H.—(1) The costs are very usually borne by both in common; (2) there is no such place, charitable institutions being compelled to decline such responsibilities.

Everybody's Mug has not confided his name and address to us.

ERRATUM.—*Anderson's College Medical School, Glasgow.*—We are informed by the house superintendent of the Glasgow Maternity and Women's Hospital, which is alluded to in our Students' Number under the heading of this school, that the fee for students for three months' attendance at the hospital is 4 guineas and 2 guineas for the nine months immediately following; and not, as was stated in the Students' Number, 3 guineas for six months.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement.

The following Congresses, Conferences, and Exhibitions are announced for September, 1911:—

April–October.—Rome Exhibition (United Italy's Jubilee).
,, 29th–Oct. 26th (Turin).—International Exhibition.
May 3rd–Oct. 31st (Glasgow).—Scottish Exhibition.
,, 6th–Oct. 31st (Dresden).—International Hygiene Exhibition (British Section opens June 14th).
May 12th–Oct. 31st (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
May 18th–October 31st (London, Shepherd's Bush).—Coronation Exhibition.
,, 19th–Oct. 31st (London).—Earl's Court Exhibition.
August 28th–Sept. 11th (South-East of France).—Eleventh "Voyage d'Etudes Médicales."
Sept. 2nd–9th (London).—Bakers' and Confectioners' Exhibition.
,, 4th–9th (Yarmouth).—Sanitary Inspectors' Association. Annual Conference.
,, 9th–11th (Ostend).—Fifteenth Flemish Nature and Medical Congress.
,, 9th–20th (Turin).—International Congress of the Applications of Electricity.
,, 11th–13th (Vienna).—German Urological Society.
,, 11th–13th (Berlin).—Third International Conference on Infantile Mortality (*Gouttes de Lait*).
,, 11th–16th (The Hague).—Thirteenth International Congress on Alcoholism.
,, 12th–15th.—Celebration of the 500th Anniversary of the Foundation of the University of St. Andrews.
,, 17th–20th (Turin).—Second National Congress of Guardians of Training Schools and Prisons.
,, 18th–23rd (Sydney).—Australasian Medical Congress.
,, 18th–23rd (Paris).—International Conference of Genetics.
,, 23rd–Oct. 21st (London, Olympia).—Electrical Exhibition.
,, 24th–30th (Karlsruhe).—Eighty-third Meeting of German Physicists and Physicians.
,, 26th–28th (Louisville, Ky.).—American Association of Obstetricians and Gynecologists.
,, 26th–30th (Brussels).—Third Congress of the International Society of Surgery and Exhibition of Fractures.
,, 28th and 29th (Manchester).—Conference of British Hospitals Association.
,, 28th–30th (Dresden).—International Congress for the Protection of Mothers and Sexual Reform.
,, 29th (Edinburgh).—Association of Veterinary Officers of Health. Annual Meeting.
,, 30th (Bruges).—Sixth Belgian Congress of Neurology and Psychiatry.
September (Genoa).—International Exhibition of Marine Hygiene.
,, (Turin).—Congress of the Association of Italian Railway Physicians.
September–November (Antwerp).—International Exhibition of Alimentation, Brewing, Wines, and Liqueurs.

Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

TUESDAY.—4 P.M., Dr. P. Stewart: Clinique (Medical).
WEDNESDAY.—4 P.M., Mr. I. Back: Clinique (Surgical).
THURSDAY.—4 P.M., Dr. C. Wall: Clinique (Medical).
FRIDAY.—4 P.M., Mr. R. E. Bickerton: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women.
THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON) Clinical Theatre, London Hospital, Mile End-road, E.

MONDAY.—2 P.M., Demonstration in Clinical Medicine:—Dr. Wall: Pulmonary Diseases.
TUESDAY.—2 P.M., Demonstration in Clinical Medicine:—Dr. Grünbaum: Diseases giving rise to Morbid Renal Excretion.
THURSDAY.—2 P.M., Demonstration in Clinical Medicine:—Dr. Head: Diseases of the Nervous System.
FRIDAY.—2 P.M., Demonstration in Clinical Medicine:—Dr. L. Smith: Diseases of the Heart.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (11th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (12th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.) Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (13th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's 2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.)., Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (16th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1911, which was completed with the issue of June 24th, were given in THE LANCET of July 1st.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1911 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A

METEOROLOGICAL READINGS.

The following journals, magazines, &c., have been received:—
Medical Chronicle, School Hygiene, Annals of Tropical Medicine and Parasitology, Guy's Hospital Gazette, Indian Public Health and Municipal Journal, Transvaal Medical Journal, Practitioner, Archives of Pediatrics, Archives of the Roentgen Ray, Public Health, Edinburgh Medical Journal, Monthly Cyclopædia and Medical Bulletin, Polyclinic, International Journal of Surgery, Dominion Medical Monthly and Ontario Medical Journal, Journal of the Royal Sanitary Institute.

Communications, Letters, &c., have been received from—

A.—Automobile Association, Lond., Chairman of; Dr. J. C. Dalmahoy Allan, Hong Kong; *The Abolitionist*, Lond.; Anglo-American Pharmaceutical Co., Lond.; Mr. W. Anderson, Aberdeen; Dr. D. A. Alexander, Clifton; Mr. R. J. Albery, Lond.

B.—Messrs. W. H. Bailey and Son, Lond.; Messrs. R. and J. Beck, Lond.; Birmingham General Hospital, Secretary of; British Hospitals Association, Lond., Hon. Treasurer of; Dr. G. F. Blacker, Lond.; Mr. J. Buchanan, Paisley; *The Bystander*, Lond., Editor of; British Medical Benevolent Fund, Lond., Hon. Secretary of; Bristol General Hospital, Secretary of; Messrs. Burroughs, Wellcome, and Co., Lond.; Mr. C. Birchall, Liverpool; Bristol Royal Infirmary, Secretary of; Dr. Samuel Bailey, Mount Ayr, Iowa; Dr. W. Cecil Bosanquet, Lond.; Dr. John Brownlee, Glasgow; Mr. G. Barrington, Lond., Dr. J. Scott Battams, Lond.; Dr. M. Cameron Blair, Lond.

C.—Mr. A. G. Coulsell, Lond.; Messrs. J. and A. Churchill, Lond.; Child Emigration Society, Oxford, Secretary of; Children's Country Holidays Fund, Lond.; Cellular Clothing Co., Lond.; Mr. G. Candussio, Parenzo; Dr. C. C. Cuthbert, Glasgow; Messrs. Corbyn, Stacey and Co., Lond.; Carnarvonshire and Anglesey Infirmary, Bangor, Secretary of; Chesterfield Hospital, Secretary of; Cornwall County Asylum, Bodmin, Clerk to the; Messrs. G. W. Carnrick Co., New York; Carlisle Dispensary, Secretary of; Dr. F. G. Crookshank, Lond.; Mr. J. P. Candler, Woodford Bridge; Mr. F. J. Colyer, Lond.; Mr. E. F. Connolly, Wimbledon; Chicago School of Sanitary Instruction, Chicago.

D.—Messrs. W. Dawson and Sons, Lond.; Dr. J. F. Halls Dally, Lond.; Mr. J. Dunlop, Lowestoft; Mr. Peter Daniel, Lond.

E.—Mr. W. A. H. Egerton, Headingley; Dr. C. T. Ewart, Claybury; Mr. H. Havelock Ellis, West Drayton.

F.—Major H. C. French, R.A.M.C., Vevey; Dr. A. M. Fraser, Portsmouth; Mr. Gustav Fischer, Jena; Hofrat Dr. S. Flatau, Nürnberg; Dr. J. Freeman, Lond.

G.—Dr. E. Glynn, Liverpool; Mr. E. W. Hey Groves, Clifton; Messrs. Goose and Son, Norwich; Mr. Henry A. Grover, Lond.

H.—Dr. C. L. Herman, Vienna; H. F. S.; Messrs. Horrockses, Crewdson, and Co., Manchester; Dr. G. Hamell, Lond.; Mr. W. Heinemann, Lond.; Miss Hamilton, Lond.; Messrs. Hawksley and Son, Lond.; Dr. F. Hernaman-Johnson, Cockton Hill; Hoffmann-La Roche Chemical Works, Lond.; Mr. H. Hadley, Lond.; Hampstead General Hospital, Lond., Secretary of; Dr. E. A. Houseman, Maidenhead; H.; Mr. Thomas Henderson, Nottingham; Dr. M. Henseval, Brussels.

I.—Incorporated Dental Hospital of Ireland, Dublin, Dean of; The Infirmary, Southport, Assistant Secretary of; International Congress of Pathologists, Turin, Secretary of.

J.—Messrs. B. Jacquemin Bros., Lond.; Dr. Hugh Jones, Liverpool; J. F. O. D.

K.—Mr. A. P. Kothare, Bombay; Messrs. G. Kelly and Co., Lond.; Dr. Knight, Edinburgh.

L.—Dr. R. Larkin, Lond.; London County Council, Clerk to the; Local Government Board, Lond., Secretary of; London School of Clinical Medicine, Dean of; Dr. H. B. Luard, Osmotherley; Messrs. Lee and Nightingale, Liverpool; Leeds Public Dispensary, Secretary of; Leicester Borough Asylum, Medical Superintendent of; Mr. F. W. Lowndes, Liverpool.

M.—Mr. H. W. G. Macleod, Lond.; Lond.; Manchester Hospital for Consumption, Secretary of; Margaret Street Hospital for Consumption, Lond., Secretary of; Maltine Manufacturing Co., Lond.; Mr. J. Y. W. MacAlister, Lond.; Dr. W. Macvicar, Lovedale Mission Station, Cape Colony; Dr. Reginald Morton, Fenton, Drem; Dr. J. J. Mullowney, Peking; Dr. J. Mackenzie, Lond.; Dr. J. N. Matthews, Codford St. Mary; Mr. R. Mosse, Berlin; Captain J. Morison, I.M.S., Bombay; Messrs. Macmillan and Co., Lond.; Dr. Murdoch Mackinnon, Lond.; Mr. J. Murray, Lond.; Mr. E. W. Marshall, Manchester; Dr. David McKail, Glasgow; Messrs. Marks and Clerk, Lond.; Mr. Rutherford Morison, Newcastle-on-Tyne.

N.—Mr. J. C. Needes, Lond.; Mr. H. Needes, Lond.; North Riding Infirmary, Middlesbrough, Secretary of.

O.—Mr. J. Offord, Lond.; One in Doubt.

P.—Mr. H. J. Paterson, Lond.; Mr. P. Phillips, Llanelly; "Printers' Ink," Lond., Manager of; Dr. A. H. Pirie, Lond.; Messrs. W. Porteous and Co., Glasgow; Peterborough Infirmary, Secretary of; Prescot Union, Clerk to the; Paterson's Advertising Agency, Dunfermline; Mr. H. A. Powell, Lond.; Mr. J. B. Pike, Loughborough.

R.—Royal Hants and Southampton Hospital, Secretary of; Messrs. Adolphe Rosenthal and Co., Lond.; Royal Albert Hospital, Devonport, Secretary of; The J. D. Riedel Co., Lond.; Royal Surrey County Hospital, Guildford, Secretary of; Royal Devon and Exeter Hospital, Secretary of; Dr. James Rae, Lond.; Dr. Norman Roberts, Washington.

S.—Scholastic, Clerical, &c., Association, Lond.; *South Wales Argus*, Newport, Manager of; Messrs. W. H. Smith and Sons, Harrogate; Major C. G. Spencer, R.A.M.C., York; Miss M. Smith, Lond.; Sirdar Rubber Co., Lond.; Mr. F. J. V. Skiff, Bad-Nauheim; Mr. W. Woods Smyth, Maidstone; Société Internationale de Chirurgie, Brussels, Secretary of; Messrs. E. H. Sellers and Sons, Huddersfield; Dr. T. H. Suffern, Calabar, S.N.; Stockport Infirmary, Secretary of; Stafford County Asylum, Medical Superintendent of; Dr. Robert Sweet, Lamlash; Sir James Sawyer, Birmingham.

V.—Dr. S. Vieira, Oporto; Victoria, Education Department of, Melbourne, School Medical Officers of; Dr. J. A. Venning, Steeple Aston.

W.—Messrs. Ward Bros., Lond.; Messrs. White and Wright, Liverpool; Mr. H. B. Wilkinson, Ivybridge; Major F. Winslow, R.A.M.C., Sheffield; Mr. A. Wander, Lond.; Fleet-Surgeon E. C. Ward, R.N., Portsmouth; Mr. D. P. D. Wilkie, Edinburgh; Dr. Henry Whitehead, Newton Heath; Dr. F. J. Waldo, Lond.; Mr. C. Stewart Wink, Halstead; Mr. E. C. Morgan Willmott, Cardiff; Mr. H. E. Waller, Moseley; Messrs. Ward Bros., Stockport; Mr. P. Carruthers Watt, Gatehouse of Fleet; Warneford, Leamington, &c., General Hospital, Secretary of; Mr. J. Williams, Bradford; Messrs. F. Williams and Co., Lond.; Mr. W. Watson, Dromore; Warrington Infirmary and Dispensary, Secretary of; Mr. S. W. Wright, Merthyr Vale.

Letters, each with enclosure, are also acknowledged from—

A.—Messrs. Armour and Co., Lond.; Messrs. Allen and Hanburys, Lond.; Ashton-under-Lyne District Infirmary, Secretary of; A. D.; A. A. H.; A. C. D.

B.—Sir Lauder Brunton, Bart., Lond.; Mr. B. Brooke, York; Broadstairs Printing and Publishing Co., Broadstairs; Mr. D. M. Bell, Pelham Manor, U.S.A.; Dr. W. H. Bryce, Edinburgh; British Drug Houses, Lond.; Mrs. Banks, Lewes; Mr. W. H. Barrett, Chichester; Mr. J. S. Beveridge, Milnathort.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only hould be forwarded.

Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Sole Agents for Advertising in Germany, Austria, Hungary, Switzerland, and the French and Italian Riviera—RUDOLF MOSSE, Berlin, S.W., and all Branches.

Agent for the Advertisement Department in France—J. ASTIER, 35, Rue Franklin, Asnières, Paris.

ABSTRACT OF A

Presidential Address

ON

A REVIEW OF THE VITAL STATISTICS OF IRELAND SINCE 1864.

Delivered before the Vital Statistics Section of the Congress of the Royal Institute of Public Health, Dublin, on August 15th, 1911,

BY SIR WILLIAM J. THOMPSON, M.D.,
REGISTRAR-GENERAL FOR IRELAND.

GENTLEMEN,—The reason for taking 1864 as the starting-point is that the General Register Office for Ireland was first opened on Jan. 1st of that year, 27 years in the wake of the English Office and nine years after that of Scotland. This office, as it is now constituted, is therefore 47 years old, although the registration of Protestant marriages dates back to 1845, so that we are able to review approximately half a century's record of marriages, births, and deaths.

DECREASING EMIGRATION.

I think we can safely say there is no country in Europe which has so steadily declined in population as Ireland since the year 1845. From a comparative view of the Census populations for nine decades it will be seen that the population increased in 1831 and 1841, and that decreases were recorded in 1851, 1861, 1871, 1881, 1891, 1901, and in 1911. We observe with pleasure that the decrease for the last decennial period is only 1·7 per cent.

The first published annual report of the Registrar-General for Ireland was that for the year 1864, and the last for the year 1910. The birth- and death-rates have varied little for the past 30 years; the marriage-rate shows an upward tendency, and the rate for emigration a decided fall. We have good reason to be pleased with the birth-rate, seeing that in France, England, the United States, and other countries it shows a steady and continuous decrease. That it has shown so little variation in this country is the more remarkable, having regard to the high rate of emigration during the past 30 years, and to the fact that practically 85 per cent. of emigrants leave between the ages of 15 and 35, the period in the life of the individual which is of the most economic value to the State. The average annual number of emigrants for the ten years 1900–1909 was 35,886—a very great decrease on the ten years 1890–1899, the average annual number emigrating being 44,955—while going back for a further decennial period, 1880–1889, we get the appalling average annual number, 80,491. Comparing the number of emigrants last year, 32,457, with this figure, 80,491, we see that the emigration-rate in the ten years 1901–1910 was practically only half what it was in the decade 1881–1890. The emigration figures for the present year, up to the end of July, show a decrease of 353, as compared with the same period of last year. The average yearly decrease in emigration for the period 1900–1909 is having its effect on the marriage-rate, which for the past 20 years has, if anything, increased, a good sign of increasing prosperity, as it is generally recognised that people do not engage in matrimony in times of commercial or agricultural depression.

PRINCIPAL EPIDEMIC DISEASES.

If we investigate the death-rate further, which in the period under review has shown a tendency to fall, we find that the deaths from practically all the principal epidemic diseases have become less in number. Taking quinquennial periods from 1866 to 1910, in the first of these periods the rate for scarlet fever was so high as 5·5 per 10,000 living, at which figure it remained for about 10 years. It then commenced to fall and has continued to do so steadily ever since, until it has now reached the low figure 0·3. The reduction of this death-rate is Ireland is much to the credit of the medical profession and all those working in the field of public health.

An investigation of the rates for typhus fever shows that the death-rate has fallen from 1·4 in the quinquennial period, 1871 to 1875, to 0·1 in the last period shown.

We come now to enteric fever, the death-rate for which has fallen from 1·8 per 10,000 for the period 1871–1875 to 0·8 for the period 1906–1910. Typhoid fever, considered generally, is a disease of middle life, and the saving of life at that age is a most valuable asset to the country. These three fevers—scarlet fever, typhus, and typhoid—are compulsorily notifiable diseases, and the substantial reduction of their death-rates in Ireland is a strong, and, in my opinion, an unanswerable, argument in favour of compulsory notification of infectious diseases. This point comes out more prominently and forcibly when we examine the charts for measles and whooping-cough, epidemic diseases which are voluntarily notifiable. From the chart for measles we see that the death-rate per 10,000 living was 1·9 for the period 1866–1870, and 1·4 for the period 1906–1910. Again, the death-rate for whooping-cough only shows a fall of 0·9—viz., from 3·3 to 2·4 for the same periods. The Registrar-General can only deal with figures, not with causes and effects, but this point—viz., that the death-rate for infectious diseases which are compulsorily notifiable has decreased much more than that for infectious diseases which are voluntarily notifiable—is one, in my opinion, deserving the serious consideration of all those who have the health and welfare of our country at heart.

TUBERCULOSIS.

Tuberculosis is now recognised as an infectious disease, and the active campaign carried out as a part of the propaganda of the Women's National Health Association, an association inaugurated, guided, directed, and presided over by the President of our Congress, reinforcing and coöperating with the efforts of local health authorities, has had a most telling effect since its inception in 1907, as shown in the reduction of the death-rate in four years from 2·7 to 2·3 per 1000 living, the lowest rate yet recorded. There were 1663 fewer deaths from tuberculosis in 1910 than in 1907, representing a decrease of no less than 32 deaths per week as compared with the number in 1907. We will now consider the death-rate for males and females (*a*) from all forms of tuberculosis and (*b*) from phthisis. We see these are about equal. It will be seen that the female sex has the higher death-rate between the ages 10–15 and 15–20, the figures for the first period being: females, 1·7; males, 0·9; and for the second period: females, 2·8; males, 2·1 respectively; while for all the other periods (except the last, 85 years and upwards) the male death-rate is the higher, particularly so in the period 45–55, when it is 2·7, the female rate at that period being 1·9. This is the first time this point has been so clearly brought out, and it is most instructive.

INFANTILE MORTALITY.

When we come to consider the deaths of infants under one year, our general death-rate in Ireland for such is comparatively low, and we compare favourably with both England and Scotland. The rate of infant mortality for the three countries is: for Ireland, for the year 1909, 92 per 1000 births registered; England, for the year 1909, 109 per 1000 births registered; Scotland, for the year 1908, 121 per 1000 births registered. In 1910 our rate increased slightly—95 per 1000 births. For the past few years the infant mortality rate for England has decreased, whereas ours has remained about stationary. In England and Scotland a vigorous campaign, both voluntary and in connexion with the Early Notification of Births Act, has been going on in regard to this high infant death-rate, with beneficial results in England. In Ireland the infant death-rate in Dublin, Belfast, and Cork compares somewhat unfavourably with some of the great English and Scotch towns, but the rate in the rural districts, as in all agricultural countries, is low, hence our average rate is less than three figures. There is, therefore, an opening in these three cities for good and effective work.

The principal causes of deaths of children under one year are atrophy and debility, which are practically double that of diarrhœal diseases. A large number of these deaths might be prevented. We cannot, I think, blame the mothers too much, because they have never had the opportunity of being instructed in the management of infants, and lack of nourishment from absolute poverty and the evils consequent on overcrowded and bad housing are responsible for much. Efforts in these directions, however, are now being made, both by municipalities and philanthropic associations. Ireland has been a pioneer, for instance, in the establishment of Babies'

Clubs, another of the many good works inaugurated under the auspices of your noble President.

INFLUENZA AND CANCER.

Turning now to diseases which show an upward death-rate tendency, influenza and cancer stand out most prominently. Twenty-two years ago influenza was almost unknown amongst us, but for the past 21 years it has claimed a great number of victims. The rates of death for this disease are particularly high for the two years 1892 and 1900 respectively. I think the medical profession will agree with me that the deaths from influenza are too numerous. This is owing, in a great measure, to the fact that it often comes on insidiously, and patients or their friends do not recognise its seriousness, with the result that the doctor is not called in until too late. Incidentally this leads up to another subject, the high percentage of uncertified deaths in Ireland as compared with England and Scotland. It is a well recognised fact that no profession does so much gratuitous work as the medical profession, and there is, therefore, no cause for such a large percentage of uncertified deaths, medical aid being easily procurable for our poorest people.

The other disease which has increased, not only in Ireland, but also in England and Scotland, is cancer. Last year there were no less than 3664 deaths registered in Ireland from malignant disease. The death-rate from cancer in Ireland has risen from 2·7 per 10,000 living in 1864 to 8·4 in 1910, an increase of 5·7. In England the increase has been 5·6, from 3·9 per 10,000 living in 1864 to 9·5 in 1909, and in Scotland the death-rate for this disease has ranged from 4·3 in 1864 to 9·6 in 1908, an increase of 5·3. Ireland shows a greater increase than England or Scotland. It is asserted by some medical authorities that this is more apparent than real and that the increase is due, in part at least, to a more accurate diagnosis of malignant disease. This is a theory which it is difficult to contradict definitely, and, if true, it applies equally to England and Scotland. With the advance of medical education and the introduction of post-graduate classes medical men are more scientifically trained, and, consequently, likely to be more accurate in diagnosis. Besides, certain morbid conditions are now classified as cancer that some quarter of a century ago were not placed in this category.

SUMMARY.

Summing up the deductions from this review of Irish vital statistics for the past 47 years, we find that (1) emigration has enormously decreased; (2) the birth-rate, notwithstanding emigration and a decreasing population, has remained almost stationary; (3) the marriage-rate has increased of late years; and (4) the death-rate, after many fluctuations, is decreasing. If to these we add some facts which have been brought out in the preliminary report of this year's Census, facts of such significance as would require a separate paper—(*a*) the number of inhabited houses in Ireland has increased; (*b*) the number of houses being built has also increased; (*c*) the number of families has increased; (*d*) the number of uninhabited houses has decreased—we cannot do otherwise than conclude that Ireland is to-day a better, healthier, and more prosperous country than it was half a century ago.

ELEMENTARY MEDICAL TRAINING FOR MISSIONARIES.—Much attention has recently been devoted to the preparation of missionaries for work abroad, and it has been shown that some elementary knowledge of medical subjects is a necessity for all. The time which should be spent in this study varies according to the part of the world in which the intending missionary expects to work, those labouring in isolated spheres needing the longest periods of training. Livingstone College, which makes special provision for this branch of missionary training, has arranged courses of study, theoretical and practical, suitable for the case of all men going to the foreign mission field, varying in length from nine months, which is the full session, to one week of lectures on tropical hygiene. This last is the only course which is open to women as well as men; not that it is less necessary for women to have some knowledge of elementary medical subjects, but because in their case a short course of practical nursing is probably the best preparation for missionary life abroad. The principal of the college will be pleased to advise any who will write to him at Livingstone College, Leyton, E. The new session will commence on Oct. 2nd.

A Clinical Lecture

ON THE

TREATMENT OF CONSTIPATION.

Delivered at the Queen's Hospital, Birmingham,

BY SIR JAMES SAWYER, M.D. LOND., F.R.C.P. LOND., F.R.S. EDIN.,

CONSULTING PHYSICIAN TO THE HOSPITAL; EX-PROFESSOR OF MEDICINE IN THE BIRMINGHAM MEDICAL SCHOOL; LATELY LUMLEIAN LECTURER AT THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

GENTLEMEN,—When you enter into your practice, perhaps the treatment and the cure of habitual constipation will engage your attention oftener than other details of our remedial art. Although this subject is of the tritest, it is well worth frequent revision. We must keep it always in our minds in our daily work as medical men, and it becomes us to reconsider it often by the lights, respectively and combinedly, of physiological, clinical, pathological, and therapeutic progress. In this great subject, as in so many others of ours, clinical observation and physiological investigation go on working together in converging directions, with the best results in practice, sometimes the one anticipating, and each confirming, the other.

Constipation is retarded progress of fæces from the cæcum to the rectum, or it is retention of fæces in the rectum (dyschezia), or it is both of these. In our conceptions of the causes, progress, and cure of habitual constipation we must include the knowledge that human fæces consist in great part of excrementitious matters excreted by the glands of the intestinal mucous membranes as well as of insoluble and superfluous food, mixed with intestinal mucus and biliary and pancreatic excretions. Human excrement, then, is made up of glandular and other excretions, as well as what may be called alimentary refuse. We must recognise both these factors and not contemplate the dietetic effluent only. The manifold errors of what may be called habits of life and ways of living, of defæcational effort, and of diet, which are causal as to constipation, are well understood. In their continued and persistent rectification may be found the cure, without the exhibition of drugs, of most of the slighter forms of costiveness. In a severer case, in one in which drugs, manipulative efforts, and even instrumental aid cannot be avoided, all that well-ordered and daily habits, well-directed efforts, and well-chosen diet, can accomplish—and they can accomplish much—are indispensable adjuvants of mere physicking in the cure of habitual constipation under skilled medical guidance.

There are three canons which should guide your treatment: (1) You should not leave the medicinal treatment of their constipation to your patients; (2) you should not prescribe a drug in the treatment of habitual constipation until you find that the constipation in the particular case before you cannot be cured without drugs; and (3) you should not prescribe drugs in the treatment of habitual constipation without the conjoined use of a judicious combination of the numerous adjuvants of natural alvine relief which are at your disposal, and which you should select especially accordingly to your experience of their use in practice, and combine them in particular cases of costiveness suitably to the individualities of your patients.

You should ascertain fully the characteristics and ways and circumstances of life of each patient, and then arrange the details of your treatment in each case upon such knowledge. In all therapeutics the individuality of the patient is the supreme law. None but a skilful prescriber can treat constipation best. To "open the bowels," to force the appearance of a copious "stool," cures not constipation, but only relieves for a few hours one of its symptoms.

The second of these canons you should remember, that of withholding drugs until drugless methods shall have failed, is a counsel of perfection which is basic in its aim, and should be followed generally; but the insistence of constipated patients for a purgative dose teaches one that patients are sometimes right in this matter (perhaps *fas est ab ægro doceri*), and that medicinal catharsis may give a fair

start for a cure in some cases, which you will be able to distinguish in practice, by disciplinary and dietetic methods. Sometimes an immediate evacuation is desirable, but no real cure of the malady is possible unless disciplinary and dietetic methods have play.

In costiveness our therapeutic clues arise well from an old definition of it—namely, "in constipation the fæces are hard, and may be retained from that cause, from weakness of the muscular coat of the large intestines, or from diseases of the anus, making defæcation difficult or painful." Habitual constipation is a penalty of our imperfect civilisation. It is due to habitual abstinence from emptying the rectum whenever the natural impulse thereunto, the physiological call for defæcation, is felt; it is due to habitual attempts at defæcation when seated upon the usual seat, 18 inches high; it is due to habitually diminished activity of the psoæ and iliaci, of the respiratory muscles, and of the muscular fibres of the large intestines, and to rectal paresis from rectal distension; it is due to habitual abstinence from fruits and other vegetable foods rich in cellulose. It is due in some women from habitual diminution of beverages, from the design of minimising urination. It is due to insufficient mastication of food, especially of meat. The curative treatment of habitual constipation may have to begin in the mouth, and it may be upon the dinner plate. Each of these causes is avoidable. Each of these causes must be sought out and avoided before a drug be taken for the treatment of habitual costiveness; if the avoidance of these causes should not be curative, such avoidance should concur continuously with all medicinal exhibition.

Many hearts throb to the fetich of a punctual fæx. By long-continued habit in health the act of voiding fæces can become to some extent a rhythmical process, done at a fixed time, by an acquired periodicity each 24 hours. Perhaps the best time is after breakfast. Before bed is the best time for a patient who has hæmorrhoids. Defæcation strains and protrudes piles, and the horizontal rest of a night in bed yields venous subsidence. Chosen the time, the voiding effort should be made daily, at the chosen time, whether the "call" to defæcation be felt or not. Besides this, defæcation should always be attempted immediately whensoever the rectal prompting thereunto shall arise. Such feeling, such *mens consoia recti*, should never be "put off." By putting it off the rectum empties itself, if it can, into the sigmoid flexures, or the feeling of rectal pressure subsides in the exhaustion of the local neuro-muscular sense into an unfelt rectal retention of fæces, and habitual constipation, with or without dyschezia, with or without rectal coprostasis, is caused and kept up. Perhaps this holding up of returned fæces in the sigmoid bendings may be a determinant of cancer there. Cancer there is much more frequent in men than in women. Women are more likely than are men to neglect to try defæcation at a rhythmical time; but men put off the act more than women do. Men like to defæcate at a given time, and at no other time. Again, as between the sexes, habitual constipation is more frequent amongst women than it is amongst men, from irregularity in the time of alvine effort, from procrastination therein, from intrinsic feebleness of the muscular factors of defæcation, from the wearing of waist-belts, of "stays," of corsets, of tight skirts, and from "inimbition."

The best position of the body for the complete accomplishment of the act of defæcation is the natural one, in crouching. In such a position only are the parts acting in the proper voidance of fæces in the best position for doing it; the anus is in the best position for opening and the rectum for emptying its contents, all the muscles concerned in the act are in the best position for their efficient play, and the parts liable to injury from strain are guarded by their natural protections, certain hernial orifices, for example. Failure of defæcation upon the usual seat will often at once issue successfully if the effort be renewed forthwith in the physiological attitude.

In a case of habitual constipation you should amplify and explain these considerations to the patient, and counsel acting upon them before placing perilous reliance upon purgative drugs. Further, you should keep in mind that certain faulty and habitual somatic postures are apt to lead to, and to keep up, sluggishness of fæcal movement in the larger bowel, even to coprostasis—namely, stooping forwards, slouching, and slackness of attitude and gait, and especially that form of arching backwards of the lower spine and doubling-up of the belly which occurs while sitting "all in a heap" in a large and low "easy" chair. Such habits of bodily postures are declared by the production of transverse wrinkles in the skin across the epigastrium. Look for these wrinkles in every case of habitual constipation, and counsel correction of postures which cause them. These postures hinder and hamper normal movements of the contents of the belly in many ways and with many ill-effects. They tend to the production of two more angles in the greater gut, one in the ascending colon and one in the descending colon, by an antero-posterior bend on each side, below the hepatic and the splenic flexures respectively.

So there must be physical uprightness in the cure of habitual constipation before drugging, and, if you give drugs, during their exhibition, and always, excepting during horizontal rest, afterwards. One of the many good physicians who were also fair poets wrote long ago:—

> "To lean for ever cramps the vital parts,
> And robs the fine machin'ry of its play."

Daily bodily exercise, especially out of doors and in the sunshine, favours defæcational normality. In the successful treatment of habitual constipation further helps may well be given by exercises which promote biliary flow, such as developed respiratory movements, by physical exercises which bring into play the muscles of the abdominal walls, and by such exercises as promote movement of those portions of the larger intestine in which fæcal stagnation is most apt to occur, that is in the cæcum and in the sigmoid flexures, for which last the psoæ and the iliaci must move well, as in running up stairs two steps at a stride, or as in "knees-up" exercises.

The best diet in the cure of costiveness is what is known as a mixed diet, the ordinary diet in use in English households. If, in a person living upon such diet, habitual constipation does not yield to habitual and physiological alvine effort, aided by suitable physical exercises of the kind I have described briefly to you, then food of a laxative character—that is, foods full of cellulose—should be increased in the dietary, such as cooked green vegetables, fruits, fruit jams, and chiefly marmalade of oranges. The fibres of cellulose appear to be the chief natural stimulant of the muscular movements of the intestines, as was shown, especially in favour of preparations of oranges, by certain striking experiments a few years ago.

Cathartics increase the peristaltic movements of the human intestinal canal, evacuate its contents, usually augment its mucous secretions, and often promote the separation of the secreted products which Liebig taught us it is the province of the intestines to separate from the blood and from the tissues. These medicines may be distinguished according to their energy of action as laxatives, which promote the gentle evacuation of the intestinal contents, and purgatives, which increase secretion and accelerate evacuation. This was Royle's and Headland's practical and excellent definition of them, and it is a good one to keep in mind in our prescriptions. Numerous are the cathartics at our disposal; their distinctions and several utilities are well known in medical practice.

For a case of habitual constipation which does not cure without medicines my favourite remedy is Socotrine aloes, suitably combined and exhibited as a pill, at bedtime. "Myrrh and aloes and cassia" can still make coprostatics glad: myrrh, with its old repute of giving an impetus to the digestive organs, and an increase of muscular power to the digestive canal, Socotrine aloes and cassia pulp, of each equal proportions, made into a pill of the weight of 5 grains with syrup or with castor oil. One pill or more may be given for a dose, as found to be needed, and their administration should be gradually reduced and omitted altogether so soon as may be. I give you this formula only as an example.

Many other cathartics are at our therapeutic disposal in pilular and in other forms, and you must learn to choose from amongst them by your experience in practice according to the particular indications in each patient. No case of habitual constipation can be treated by "rule of thumb." It will always be your duty to your patient and to yourself to investigate each case skilfully, by complete methods, with your full acumen, and by adequate clinical study of it, as to the causal relations and other associated details of the malady in the

individual instance of it in question, as to sex and as to temperament, and each case must be diagnosed *in propriâ personâ* and individually prescribed for, watched, and guided by an experienced adviser in the science and art of medicine. Faulty habits of life must be corrected appropriately, diet must be confirmed or rearranged if need there be, and you must make a suitable selection of medical gymnastic exercises, to restore and improve the health of the body at large, and of the intestines in particular, and fitting medicaments must be prescribed if their employment be unavoidable. And all this must be done with a lively remembrance of the manifold conditions which ever modify the effects of medical treatment, for, as one of the best therapeutists of a recent day, Dr. Scoresby-Jackson, taught, "the general habits of the patient his profession, business, or occupation, his diet, and other circumstances connected with his daily pursuits, influence the actions of medicines; and there are certain indications of treatment in the cases of the rich and the poor, the spare and the plethoric, the man of active and the man of sedentary habits, which are far more easily learned from careful clinical observation than from volumes of literature."

For counsels of perfection in the cure of habitual constipation you must win and sustain the patience and perseverance of your patient, and you must have the courage to insist that the habitual use of cathartics alone to meet a troublesome symptom is harmful, and may lead to the worst results.

A CASE OF ACUTE POLIOMYELITIS IN AN ADULT.

BY C. M. HINDS HOWELL, M.D. OXON., F.R.C.P. LOND.,
PATHOLOGIST TO THE NATIONAL HOSPITAL FOR NERVOUS DISEASES, DEMONSTRATOR OF PHYSIOLOGY AT ST. BARTHOLOMEW'S HOSPITAL, PHYSICIAN TO THE GREAT NORTHERN HOSPITAL;
AND
B. T. PARSONS-SMITH, M.D., B.S. LOND.

CASES of acute paralysis of sudden onset, rapid progress, and fatal termination are fortunately not common, if vascular lesions of the brain are excluded. The difficulties of correct diagnosis in the early stages of such attacks of acute paralysis are very considerable, and in a large number of fatal cases no adequate pathological examination has been obtained. There is a special interest therefore attaching to cases in which a microscopical examination has been possible, and it is for this reason that we think the details of the following case, which occurred in the practice of one of us (B. T. P.-S.), worthy of record. It is greatly to be regretted, however, that the circumstances of the case did not allow of a perfectly satisfactory pathological examination being made. Although it was quite possible to make a definite diagnosis from the material which was obtained, no bacteriological examination was made, nor were any inoculation experiments on monkeys or other animals possible. The following is a brief record of the clinical aspects of the case.

The patient, aged 22, complained of headache and general debility on August 22nd, 1910, which compelled him to return early from business. His previous health had been very good, and so far as is known he had not been exposed to any infection previously to the onset of his illness. It is noteworthy that a brother shared his room with him, and had been in close contact with him in the period immediately preceding the onset of the illness. This brother and the other members of the family remained in perfect health. The patient passed a very restless night on August 22nd, and his condition was obviously worse the next morning. He vomited frequently, the pulse was rapid, and he was evidently extremely ill. During the evening he complained of severe pains in the lower part of the back, and at the same time noticed that the legs were decidedly weak. During the night power in the legs was completely lost. On examination the following morning the patient was observed to be lying perfectly still, breathing with some difficulty, and at a rapid rate—viz., 38 per minute. The pulse was 120, of small volume and low tension. The face was pale and perspiring, the mouth was open, and the alæ nasi working. The temperature was 100° F. Intelligence and memory were unimpaired. With regard to the motor system, movements of the head and facial muscles were possible, and there was no ocular palsy or other cranial nerve defect at this time. The upper extremities were markedly paretic, and coördinated movements were carried out only with great difficulty. There was marked hypotonia of the muscles. The trunk muscles were more affected, the intercostal muscles acting hardly at all, and the diaphragm only very weakly. The patient was quite unable to make any attempt to raise himself in bed. The lower limbs were quite powerless and flaccid. Sensation was absolutely normal, the patient recognising all forms of sensory stimuli readily, naming them correctly and without difficulty. The deep reflexes (sphincters) were unaffected, but the tendon reflexes were all absent, and no superficial reflex could be obtained. During the afternoon the paralysis progressed rapidly and became complete in the trunk and upper limbs. It spread further, however, and involved the tongue and facial muscles to some extent. Speech now became slow and difficult, though consciousness was fully maintained. Respiration became more shallow, and the patient died at 8.30 P.M. on August 24th, two days after he was first taken ill.

The spinal cord and a portion of the cerebral cortex were received for microscopical examination. Sections were made and stained by the following methods—Marchi, Nissl, and hæmatoxylin and Van Giessen.

Cortex.—Nothing abnormal was found in the portions of cortex examined, nor in the meninges, blood-vessels, or nerve cells.

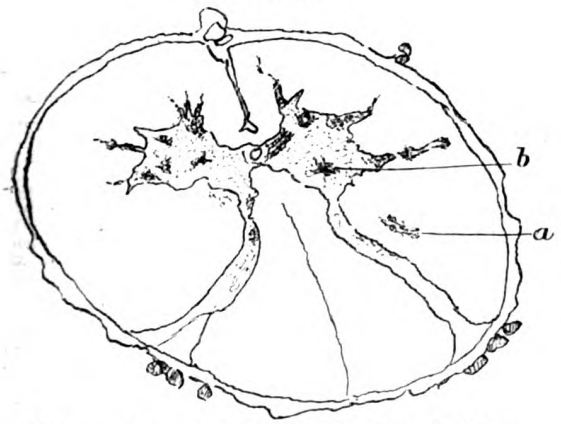
Spinal cord.—The Marchi method, as might be supposed, owing to the rapid course of the disease, showed no changes. In the following examinations the hæmatoxylin and Nissl methods were used:—1. Meninges: For the most part the meninges were quite normal, and there was no widespread inflammatory exudation into them. In a few places, however, particularly in relation to the anterior spinal artery, posterior spinal arteries, and in the anterior fissure of the cord there was a slight amount of small, round-celled exudation, which was most conspicuous in a perivascular distribution, though it extended actually beyond the immediate vicinity of the blood-vessels. 2. Blood-vessels: (*a*) Meningeal blood-vessels: No gross defect was noted in connexion with these, beyond the patchy perivascular exudation referred to above. There was no evidence of thrombosis, though the vessels were considerably engorged. (*b*) Intra-medullary vessels: The same perivascular cell exudation was to be seen in these vessels both in the white and grey matter. The vascular engorgement was marked, but there was no evidence at all of any thrombosis having occurred. The cells of the inflammatory exudation seemed to be almost all of the lymphocytic type, but there were a few endothelial cells also present. Polymorphonuclear cells were conspicuously absent. 3. The spinal cord itself: Throughout the whole cord from the sacral to the cervical region the grey matter macroscopically had appeared darker than normal, and on making microscopical sections was found to be the seat of widespread inflammatory changes. The extent and distribution of these changes are indicated in the diagrams (1, 2, 3). It will be seen that, with the exception of the perivascular exudation in the meninges and in the white matter, the inflammatory changes are confined to the grey matter. It will at once be evident, on glancing at the diagrams, that the cell exudation is not confined to the anterior horns, but that the changes are very intense also in the vicinity of Clarke's column and in the posterior horns. The inflammatory change in the grey matter was diffuse throughout the whole length of the cord, while here and there dense foci of cell collections were to be seen. Some of these were perivascular, but the majority did not appear to be so. The cells of this inflammatory exudation were, in part at least, lymphocytiic in character, but there were numerous other cells the nature of which it was not easy to determine. They did not appear to be derived from the blood, and were probably in part derived from the vessel wall, and in part a product of neuroglia proliferation. A few plasma cells were seen, but they were rare.

With regard to the nerve cells of the grey matter, a striking feature was the alteration in the ventral horn cells. Both in the cervical and lumbar enlargements many of these cells had disappeared altogether, or existed as mere ghosts of their former selves. Those that remained showed every stage of

chromatolysis, and practically not a single quite normal ventral horn cell remained. The cells of Clarke's column appeared to have survived better than the ventral horn cells, but they, too, were seriously affected. Unfortunately, the bulb and pons were not available for examination, so it was impossible to determine the upper limit of the inflammatory process, but clinically it had reached the facial nucleus in the lower part of the pons. The involvement of the pons only occurs in very severe cases, and is uncommon even in them.

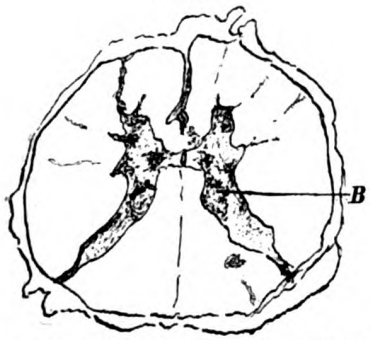
The pathological evidence makes it quite clear that the case was a very severe and widespread one of acute poliomyelitis. The clinical evidence during life was not so conclusive, the first diagnosis, which was offered tentatively, being that of Landry's paralysis, the chief reason for this diagnosis being the ascending character of the paralysis, the patient's age, and the absence of sphincter involvement.

FIG. 1.



Upper cervical segment of spinal cord. Diffuse infiltration with foci of more acute inflammatory reaction (*b*), chiefly in anterior horns, but the posterior horns have not escaped. Vessels in white matter (*a*) show perivascular exudation of small round cells. (Edinger projection × 5.)

FIG. 2.

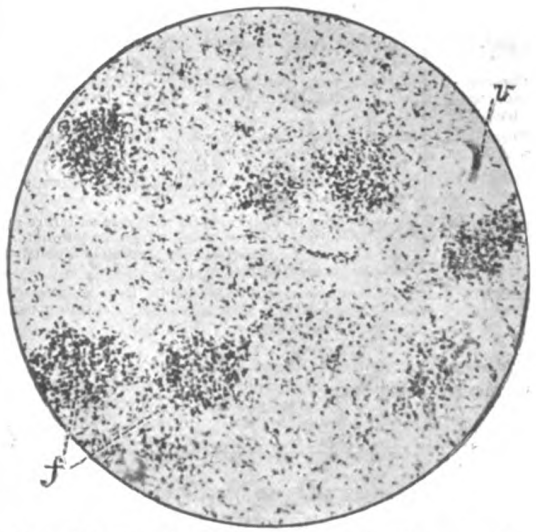


Lower dorsal segment of cord. Infiltration of whole of grey matter. Clarke's column suffers particularly. Intramedullary vessels of white matter show inflammatory changes. B = microphotograph, Fig. 5. (Edinger projection × 5.)

FIG. 3.

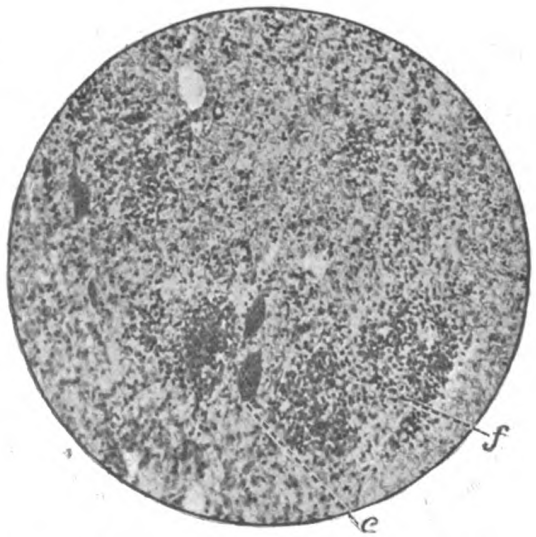
Lumbar segment of cord. Intense inflammatory reaction in posterior horns, as well as anterior. Destruction of ventral horn cells. Inflammatory perivascular exudation in meninges. A = microphotograph, Fig. 4. (Edinger projection × 5.)

FIG. 4.



Microphotograph of part of ventral horn of lumbar segment (vide A, Fig. 3). Note absence of motor cells, and diffuse inflammatory exudation, with patches where this is very intense. *v* = Surviving but damaged ventral horn cell. *f* = Foci of acute inflammatory exudation.

FIG. 5.



Microphotograph of cells of Clarke's column showing intense inflammatory exudation in their vicinity (vide B, Fig. 2). *c* = Cells of Clarke's column. *f* = inflammatory exudation.

None of these features are, however, incompatible with a diagnosis of acute poliomyelitis. In cases of acute paralysis of this kind there are four possible conditions to consider, as Dr. E. Farquhar Buzzard pointed out in his Goulstonian lectures in 1907.[1] These are: (1) acute poliomyelitis; (2) Landry's paralysis; (3) acute toxic polyneuritis; and (4) acute

[1] THE LANCET, March 16th (p. 705) and 23rd (p. 785), 1907.

ascending myelitis. Is it possible to make a certain diagnosis between these conditions during life? Up to a certain point it is, but errors have been made in the past, and will no doubt be made again even by those who have had most experience of these particular forms of infective or toxic conditions of the central nervous system. Acute ascending myelitis is probably the easiest to recognise with certainty, owing to the fact that there is most pronounced sensory loss which ascends *pari passu* with the paralysis, and that the sphincters are early affected. The following points are of some value in making a differential diagnosis, and for the sake of clearness they are arranged in tabular form. It must not be supposed, however, that exceptions do not occur to the brief descriptions set forth below.

Table in which are Particularised Some Points which are Helpful in Making a Differential Diagnosis.

—	Acute poliomyelitis.	Landry's paralysis.	Acute toxic polyneuritis.	Acute ascending myelitis.
1. Onset.	Sudden; progress rapid.	Sudden; progress less rapid.	Onset and progress more gradual.	Sudden.
2. Constitutional symptoms.	Often severe. Temperature 101–103° F.	Not so severe; little or no febrile disturbance.	Often no constitutional disturbance.	Severe; often great constitutional disturbance.
3. Muscular condition.	Flaccid palsy; as a rule some groups of muscles more affected than others. Rapid muscular wasting. Cranial nerves rarely affected.	Flaccid palsy; more uniform distribution. Little muscular atrophy. Cranial nerves rarely affected.	Peripheral muscles more affected than proximal groups. Cranial nerves not uncommonly affected.	Ascending paralysis involving successive segments of the spinal cord.
4. Sensory symptoms.	Severe pains in back and on passive movement common in early stages. No loss of cutaneous sensibility.	Severe pain rare; paræsthesiæ not uncommon. No loss of cutaneous sensibility.	Paræsthesiæ common; tenderness on pressure. Some degree of loss of cutaneous sensibility common.	Pain in back common. Marked degree of loss of cutaneous sensibility; ascending with paralysis.
5. Reflexes.	Deep reflexes abolished in affected muscles. May have extensor plantar in early stage.	Deep reflexes absent. No extensor response.	Absence of all reflexes.	Lost as disease progresses, but may be + in legs with extensor plantar.
6. Sphincters.	Unaffected.	Unaffected.	Unaffected.	Affected early.
7. Prognosis.	Good as to life, except in very severe cases.	Not so good as to life, but muscular recovery likely to be more complete.	Good as to life and recovery of muscular power.	Exceedingly bad.

FURTHER OBSERVATIONS ON THE TREATMENT OF HAY FEVER BY HYPODERMIC INOCULATIONS OF POLLEN VACCINE.

BY J. FREEMAN, M.D. OXON.

(*From the Laboratory of the Department for Therapeutic Inoculation, St. Mary's Hospital.*)

THIS paper is the sequel to Mr. L. Noon's paper on Hay Fever in THE LANCET of June 10th, 1911, in which was described research work for treatment by hypodermic inoculations of pollen toxin.

Previous Work.

Dunbar had described a simple ophthalmo-reaction as a diagnostic test for that susceptibility to pollen which constitutes hay fever; a watery extract of pollen of a certain strength dropped into the eyeball of a normal man produces no effect, but will cause a miniature attack of hay fever in susceptible persons. The test is quantitative in nature, and by noting the dilution of pollen which will just cause the eye to react it is possible to obtain some measure of the patient's susceptibility. Changes in susceptibility presumably have an inverse correlation with changes in immunity to the pollen toxin, and Noon applied this quantitative test to the study of changes in immunity produced by subcutaneous inoculations of pollen vaccine. In this way he demonstrated that *suitable* doses of pollen toxin increased the patient's immunity, while unsuitable doses either did not affect, or even decreased, this immunity; this brings the pollen inoculation work into line with the bacterial inoculation work of Wright and his school. These points established, Noon set to work to immunise hay fever patients during the off season in preparation for the season which we have just passed through. Unfortunately, circumstances compelled him to give up work last February, and the research passed into my hands; it is now possible to tabulate some laboratory data about these and subsequent inoculated hay fever cases, and also to give the clinical results of the treatment as disclosed by the past summer season.

Laboratory and Clinical Evidence in Table.

Explanation of table.—Adjoined is the tabulated list of the 20 cases treated on this system by hypodermic inoculations of pollen toxin; it is important to note that the list is not a collection of flattering "unsolicited testimonials," but gives an account of every case which had any systematic treatment, excluding only one or two people who were seen once and then lost sight of.

The first column gives the reference number of each case. The cases are arranged in the order in which they arrived for treatment; those who were already suffering from hay fever when they first presented themselves are marked with an asterisk.

The second column gives the dates of the beginning and end of treatment; these dates refer especially to the parallel figures in the next two columns.

The third column gives the state of pollen-immunity as judged by the ophthalmo-reaction at these dates. The unit of measurement here employed was explained fully by Noon in his paper last June; it is convenient shortly to redescribe it here. The quantitative measurement of the ophthalmo-reaction is made by noting the weakest dilution of pollen extract of which one drop, when dropped on the eyeball, will just produce a slight flushing of the inner canthus of the eye. The unit of measurement is a one-millionfold dilution of Phleum pratense pollen in water—which is spoken of as one unit of pollen, or shortly as 1 U.P. Thus, a hundred-thousandfold dilution of pollen would equal 10 U.P., a thousandfold dilution would equal 1000 U.P., and so on.

The fourth column gives the hypodermic doses of pollen extract which were used at these two dates respectively; these doses are also given in terms of pollen units, 1 U.P. being 1 cubic centimetre of the millionfold extraction, or, to put it another way, the amount of pollen toxin extracted from one-millionth of a gramme of Phleum pratense pollen.

The fifth column gives a short summary of the fate of the patients during the hay fever season this year as reported by the patients or their friends.

In the sixth column I sum up my own impression of the case.

Laboratory evidence in table.—In studying this tabulated list of inoculated cases, the first point to be noted is the increased tolerance of pollen toxin which was produced by the inoculations in every case. This is shown in Column 3 by the ophthalmo-reaction which the patient gives at the beginning and end of treatment; and as the personal equation, the "functional error," of the observer enters very little into the results of this reaction, it is claimed that this change in the ophthalmo-reaction represents an undoubted change in the immunity of the patient.

Then, again, it is clear from Column 4 that the doses also were increased. Now, it was found by experiment that it

was impossible at the commencement of treatment to give much larger inoculations than those indicated in the list without producing symptoms of an overdose—symptoms clinically, and as noted in the laboratory by a falling off in the ophthalmo-reaction. If the dose *were* increased markedly, one might produce even in mid-winter such unpleasant things as swelling, pain, and urticaria at the site of inoculation, a general malaise, and all the nose and eye symptoms of a thorough attack of hay fever. Yet as immunisation progressed it was found by repeated ophthalmo-reactions that larger doses could be given with advantage, and though some of these were enormously greater than the initial dose, they were given without any clinical symptoms and without lowering the ophthalmo-reaction.

As denoted by the asterisks, most of the people at the end of the list were already suffering from hay fever when they came, but it was found that in these cases also there was an increase in immunity and an increase in the dose employed. The original scheme was one of prophylactic immunisation, and this was much more suitable for the preliminary research work because the effects of each dose could not be obscured by chance doses of pollen from the atmosphere; but clearly phylactic inoculations are of more use if only they will answer reasonably well. At first thought it might be argued that phylactic doses of pollen toxin will only add poison to an already poisoned patient, but this objection is no more valid in the treatment of hay fever than it is in the treatment of boils by staphylococcus vaccine; the answer is the same in both cases. Though it may or may not be true that at the seat of the disease the tissues are over-poisoned, yet the rest of the body may, under the stimulus of an inoculated vaccine, respond by an increased production of antibodies; this surmise is justified when it is found that such an inoculation *is* followed by a demonstrable increase in immunity.

Case.	Month and year.	Resistance.	Dose.	Patient's opinion.	Writer's opinion.
1	July, 1910. May, 1911.	40 U.P. 5000 U.P.	4 U.P. 2000 U.P.	Extremely bad with hay fever for last four years. Inoculated persistently during the off season; stopped treatment in May. Tested well, but absolutely immune.	Eminently satisfactory.
2	July, 1910. (Did not continue.)	40 U.P.	2 U.P.	Refused treatment owing to article on anaphylaxie. Had hay fever worse than ever this year.	(Satisfactory.)
3	Sept., 1910. May, 1911.	20 U.P. 400 U.P.	4 U.P. 120 U.P.	Inoculated irregularly and also with two bacterial vaccines. Had hay fever, but probably not so bad as formerly, and was sooner over.	Disappointing.
4	Feb., 1911. May, ,,	20 U.P. 170 U.P.	6 U.P. 25 U.P.	Certainly much better, though not clear of hay fever.	Fairly satisfactory.
5	March, 1911. June, ,,	40 U.P. 400 U.P.	18 U.P. 20 U.P.	Has been practically free from hay fever this season, but has felt "on the verge of it" once or twice. Went in hay fields, motored, &c. (which was impossible formerly).	Satisfactory.
6	March, 1911. June, ,,	40 U.P. 1000 U.P.	12 U.P. 100 U.P.	"Have had no hay fever this year, except one attack lasting an hour after walking through a hay field, and no asthma. In former years had bad hay fever for at least six weeks and asthma at night."	Eminently satisfactory.
7	April, 1911. July, ,,	6 U.P. 1000 U.P.	2 U.P. 18 U.P.	"I think I may fairly say that though I had it pretty badly occasionally, it was not in so severe a form nor so easily excited. Susceptibility diminished, perhaps one-third. Effects less pronounced in the same proportion."	Inconclusive.
8	May, 1911. June, ,,	13 U.P. 170 U.P.	4 U.P. 20 U.P.	"Quite a marked improvement, if not an absolute cure."	Moderately satisfactory.
9	May, 1911. June, ,,	40 U.P. 500 U.P.	4 U P. 25 U.P.	This case was handicapped by the inoculations being given rather irregularly. "The attacks were less violent on the whole, and certainly did not last as long."	,,
10*	May, 1911. June, ,,	130 U.P. 170 U.P.	4 U.P. 10 U.P.	Did not improve after several inoculations, and as he could with difficulty spare the time he decided to postpone the treatment for prophylaxis in the winter.	Failure.
11	May, 1911. July, ,,	13 U.P. 170 U.P.	1½ U.P. 10 U.P.	Had a little sneezing, but was clear of hay fever most of the time—probably not a very severe case. He reported, "the cure still continues to work marvellously."	Satisfactory.
12	May, 1911. June, ,,	40 U.P. —	4 U.P. 10 U.P.	"I do not want to boast, but I think I am quite done with the accursed thing for this year. There can be no sort of doubt, seeing the kind of season it has been, that I should have suffered, and that severely, if I had not had these inoculations."	,,
13*	May, 1911. June, ,,	5 U.P. 17 U.P.	1 U P. 5 U.P.	"I *did* have a return of the hay fever after the cure" (i.e., three inoculations), "but only slight, and have not had it for over three weeks now."	,,
14*	May, 1911. July, ,,	170 U.P. 500 U.P.	10 U.P. 15 U.P.	"Since the inoculations began I have had practically no running at the eyes and nose, nor do my eyes get bloodshot."	Fairly satisfactory.
15	June, 1911. June, ,,	170 U.P. 500 U.P.	10 U.P. 300 U.P.	A Canadian who gets bad hay fever in August, but not earlier. Has had none this year up to date.	No test.
16*	June, 1911. June, ,,	17 U.P. 170 U.P.	1 U.P. 6 U.P.	"She is certain that the condition improved after the third, and she thinks it was better after the second dose. Afterwards she had very little return of symptoms till treatment was discontinued, when there was a slight return."	Satisfactory.
17*	June, 1911. July, ,,	5 U.P. 50 U.P.	1 U.P. 6 U.P.	Reported a distinct improvement after the second and third doses, and had no hay fever after the fourth.	,,
18*	June, 1911. July, ,,	170 U.P. 1700 U.P.	10 U.P. 50 U.P.	Reported himself very much better after the second dose, and was clear of hay fever from June 16th onwards.	,,
19*	June, 1911. June, ,,	5 U.P. 17 U.P.	1 U.P. 3 U.P.	"The hay fever inoculations, although I came to you having hay fever rather severely, did me an immense amount of good, and I intend next spring ..."	Fairly satisfactory.
20*	June, 1911. July, ,,	17 U.P. 150 U.P.	1 U.P. 5 U.P.	"First inoculation (given during severe attack) gave immunity for two days. Second gave complete immunity from Monday till Sunday. Third (rather stronger than before) brought on attack which lasted three days. I have perfect confidence in its power of giving immunity if the right strength is found."	Satisfactory.

Thus, Columns 3 and 4 both denote an increase in pollen immunity during treatment. This increase as here shown varies partly no doubt with the individual, but also with the thoroughness with which the inoculations were undertaken. It might be thought that both an increased ophthalmo-reaction and tolerance of an increased dose were tests of the same thing, and that therefore they must run parallel; this was not the case. At the commencement of treatment the dose could not with advantage be increased as rapidly as the increase of the ophthalmo-reaction, while at the end of treatment there was a tendency to a sticking-point in the ophthalmo-reaction, but the dose could gradually be made larger without producing symptoms either clinical or laboratory.

It is claimed that this increase in immunity produced by pollen vaccine is in itself the best proof of the soundness of this line of treatment, whether prophylactic or phylactic. It is true that one does not know if this increase is sufficient for all purposes, but the change is certainly in the right direction, and must be doing good.

Clinical evidence in table.—In judging a system of treatment by "results" there are obvious sources of error which should be taken into account; and in criticising Column 5 let us give due weight to (1) the natural bias of the operator; (2) the bias of the patient; and (3) outside circumstances—i.e., luck, affecting the result. Every medical man so desires that his patient's condition shall be improved by his treatment that there is a constant tendency to detect such improvement in adventitious fluctuations of health. To avoid this danger most of the results were summarised for me either by the patients or their friends. On the patient's side there is also the desire for improvement, reinforced by the impression made on the mind by a rather novel system of treatment and a certain atmosphere of "science." As a set-off to such faith-healing, most of the patients had undergone several "cures" which they had been told were infallible, and they therefore submitted themselves to treatment in a critical, sceptical, or even hostile spirit. There is another point: any one who works at hay fever research will have a highly intelligent and critical material to work with—a very high proportion of the people in the above list have been accustomed by their position or employment to give discriminating judgments. Lastly, luck, or outside circumstances; was this year a better year for hay fever patients? Apparently not. The general, though not universal, opinion seems to be that the season was, on the contrary, more severe than usual—that it began and ended earlier. As some test of the season many of the patients were urged to select another hay fever case as similar as possible to themselves as a control case for observation; all these controls had much worse hay fever than the inoculated patient.

Considering all the cases generally, there seems little doubt that there has been a distinct amelioration of symptoms. This improvement took several forms; a greater freedom from attack, the attack not so bad as in former years, and the attack sooner over, the constitutional disturbance not so great, less asthma. The people who had already developed hay fever when they commenced treatment were, perhaps, the most generous in their comments, possibly because they had recently had a reminder of what hay fever was like.

Application of Treatment.

Diagnosis.—It remains to be considered how this treatment is to be turned to account prophylactically next winter and spring, and phylactically next summer. Whatever the treatment, the diagnosis is important; though an uncomplicated case will usually present no difficulty, yet it is sometimes convenient to have a test of susceptibility to pollen toxin, and this is almost a necessity when prophylactic inoculations are to be commenced in the off season. But there are many reputed cases of hay fever which are partly, and even wholly, caused by a bacterial infection; indeed, it seems probable that an attack of hay fever may be the starting point of a bacterial infection, or that a catarrh of the air passages may predispose to hay fever, and before treatment of any kind it is essential to disentangle these two factors. During the present research several so-called hay fever cases were excluded from treatment because the eyeball was unaffected by pollen toxin—one of these confessing to malingering, and the remainder being the victims of bacterial infections. A case treated by a colleague is a good illustration of the value of a diagnostic test. A lady reported to have hay fever had slightly inflamed eyes which streamed with clear tears; as she did not react to pollen toxin hay fever was excluded. The tears were found to be swarming with staphylococci, a vaccine was made, and in a short time the symptoms disappeared.

In the list of cases treated last season the first ophthalmo-reaction will be seen to vary between 5 U.P. and 170 U.P.; those who did not react to 5000 U.P. were said to give a negative test; there were no unaccountable cases—i.e., people whom subsequent events proved to have been negative giving a positive result, and *vice versâ*.

Initial dose.—Whether or no the help of such a test is required in fixing the diagnosis, it will at any rate be required in fixing the initial dose, should vaccination treatment be decided on. Noon suggested as a suitable initial dose one-third of a cubic centimetre of that dilution of pollen toxin which gives the ophthalmo-reaction. On this plan a man giving a diagnostic reaction of 6 U.P. would receive 2 U.P. hypodermically, and a man who reacted to 100 U.P. would receive 33 U.P. This seems to be about correct, or perhaps to err on the side of over-dosing, especially when hay fever is already developed. In this connexion it should be said that the cases in the tabulated list are not all to be taken as models, as experience was being gathered all the time. In addition, there were several deviations from the ideal course to suit special circumstances.

Subsequent doses.—The patient was, as a rule, re-inoculated every week or ten days: the larger doses were given after a longer interval, while the very small doses were repeated after three or four days. Those cases which were being treated phylactically usually finished treatment with the fifth or sixth dose, the prophylactic inoculations were naturally much more numerous, as an attempt was being made to produce as high an artificial immunity as possible.

All these doses were determined on with the assistance of ophthalmo-reactions. These were taken not only at the time of inoculating but also frequently between the doses; and it is urged that whenever this is possible it enables the operator to mark the success of his treatment, to detect mistakes, and, if necessary, to adapt his doses to the idiosyncrasies of his patient. Clearly that dose should be selected which will give the greatest increase to the immunity of the patient; if a dose or a series of doses fails to increase the patient's immunity as measured by the ophthalmo-reaction, then it is to be presumed that the dose is either too small to be efficient or so large as to be overdosing the patient, and this latter will be the case if the resistance of the patient is not only not increased but is even diminished after the doses. As a result of such tests it was generally found advisable not to increase the dose quite as rapidly as the increase in the ophthalmo-reaction, at any rate at first. Later in the process of immunisation the ophthalmo-reaction ceased to rise so quickly, and it was sometimes possible to regain the 1 : 3 ratio between the dose and the reaction. Lastly, in the case of very highly immunised patients—e.g., Case No. 1—the ophthalmo-reaction at last became stationary, but the dose was still increased.

It is, perhaps, possible by the ophthalmo-reaction to detect three stages in immunisation. In the first stage favourable doses are followed by an immediate rise in resistance, but should not be followed by a corresponding increase in the size of the next inoculation. In the second stage a larger dose is required, giving first a slight negative phase followed by a slow rise in immunity. In the final stage the eye reaction becomes stationary, but apparently the doses may be increased with advantage so long as there is no evidence, either laboratory or clinical, of an overdose.

Rule-of-thumb inoculations.—Owing to the nature of hay fever there is no danger to life and only temporary danger to health by inoculating "blindly"—i.e., without controlling the doses by ophthalmo-reactions; but it is thought that in order to make a diagnosis and to fix the first dose, at least one eye-testing will be necessary. As a rule-of-thumb, the second and third doses seemed to be usually half as much again as the first dose, while the fourth, fifth, and sixth are perhaps twice as much as the first, though in several cases the size of the dose was increased more rapidly than this.

Pollen supply.—With regard to the pollen extract necessary for testing the eye and for injecting as a vaccine, Dunbar's method of extraction is to be followed. The brief directions given by Noon in the previous paper should enable anyone, who has sufficient time and a laboratory, to construct his own pollen dilution. This will prove inconvenient to many, and it is proposed that the Inoculation Department of St. Mary's Hospital shall make arrangements to put these dilutions of pollen toxin on the market through Messrs. Parke, Davis, and Co., the proceeds to go to the upkeep of the department as in the case of their bacterial vaccines.

A final word as to the species of pollen employed. Noon selected that of timothy grass (Phleum pratense), because the pollen of this grass gave in his hands the strongest extract as tested on the eyes of the patients. This spring I tested various pollens as they matured, rushes, sedges, grasses, &c., but none gave so strong an extract as this timothy grass. The pollen of Alopecurus pratensis gave good results, but only possessed one-quarter the strength of Phleum pratense. The grasses and flowers dreaded by the hay-fever patients differ considerably in different cases, and the question arises—Is one kind of pollen more active in one case and another in another case? Though the question

cannot be regarded as settled, apparently this is not so. For one reason, the ratio between the strength of, say, a phleum extract and an alopecurus extract remains about the same with different patients—i.e., 4 : 1. Furthermore, a patient inoculated with alopecurus pollen vaccine is found to become immune to the phleum pollen extract as tested by the ophthalmo-reaction. Apparently, therefore, we need not select different types of pollen for treating different patients.

Devonshire-place, W.

SOME POINTS IN INJURIES TO THE ELBOW-JOINT.

BY R. LANE JOYNT, F.R.C.S. IREL.,
SURGEON TO THE MEATH HOSPITAL, DUBLIN.

INJURIES to the elbow-joint form a very large proportion of the cases submitted by surgeons to X ray examination, and of these a great number are cases of supracondylar fracture with displacement backwards of the bones of the forearm together with the small lower portion of the humerus. In an X ray examination of this injury (the supracondylar fracture) it is quite impossible at times to decide how much of the humerus is damaged; whether it is an epiphyseal separation or a true fracture above it. This difficulty is due, first, to the cartilaginous and transparent nature of the end of the humerus in children, and, secondly, to the extreme difficulty of keeping a child's upper arm steady during the X ray exposure, however short it may be. A displaced epiphysis may be replaced by the time the radiographer is asked to examine it, and if it goes back accurately into place he cannot tell in a recent injury whether it had been displaced or not. The difficulty of steadying a child's upper arm, and even the upper arm of adults, during an X ray exposure is well known to radiographers. Unsteadiness results in a blurred photographic plate and only gross injuries are decipherable. The lower fragment in any case is so small that the displacement is almost identical with that due to a true dislocation.

Simple dislocation of both bones backwards is a very rare injury in children, and any surgeon having to deal with a case presenting signs of backward displacement of the forearm in a child should suspect fracture of the humerus just above the condyles.

The readiness with which, in supracondylar fracture, the deformity can be reduced, only to recur at once when the limb is let go, and also the readiness with which the deformity recurs when the limb is actually put in splints, is well known to all who have handled such cases. It is therefore imperative, if the surgeon wants to protect himself against blame, as well as to furnish himself with the accurate knowledge that leads to successful treatment, that such cases should be radiographed some days after the limb is in the splints in order to make sure that the deformity has not recurred. To this end, splints should be used of wood or aluminium, or if of metal should be of the hoop iron pattern applied on the outside of the limb, so as to allow an X ray photograph to be taken without undoing the splint. If the bones are in good position no harm is done, and if not further attempts can be undertaken to correct the position of the bones.

Mr. Robert Jones of Liverpool has drawn the attention of the profession to the difficulty of treating these cases, and his paper read before the Surgical Section of the Royal Society of Medicine, and published in THE LANCET of Nov. 19th, 1910, p. 1479, is a masterpiece in the literature of joint injuries. I have adopted his method of treating these injuries in the first case by putting the limb up in a very flexed position, not an easy thing to accomplish with the ordinary splints, which do not go beyond a right angle. If splints are to be applied in the case of a child, cardboard cut like a V can be placed on the under side of the arm, or a thin strip of tin plate or light hoop iron or aluminium can be placed on the outer aspect of the bent limb, the metal being bent on the flat. Passive movement to "establish the right of way" should be begun early—that is, after seven days—and the direction "cause no pain" attended to during movement.

Fracture of the coronoid process of the ulna is, if it occurs at all, an extremely rare condition—that is, tearing off of the tip of the coronoid without fracture of the shaft of the bone. That is an injury to the bone similar in character to a fracture of the styloid or olecranon, and not associated with other injuries but dislocation.

My experience as an X rayist dates from 1896 (Roentgen's discovery was in 1895) and I am still actively engaged in this work, and up to the present I have never seen a case that to my mind presented unmistakeable signs of this injury in a "negative."

Mr. Jones points out the frequency with which, after apparently simple dislocation backwards of both ulna and radius, bony growths occur in the brachialis anticus muscle—a myositis ossificans. This condition I have met with on numerous occasions, all resulting from dislocation, and the subject was recently dealt with in the *Annals of Surgery* by an American writer.

The occurrence of bony growths in the muscle begins always near the coronoid and spreads upwards, and it seems to me that the muscle is torn near its attachment and does not lift off a plate of bone in the same way that the ligamentum patellæ does when it is torn from the tibia, or as the tendo Achillis does when separated from the os calcis.

Skiagrams show that in dislocation of both ulna and radius backwards at the elbow the tip of the coronoid process never gets beyond the lowermost point of the trochlear surface of the humerus. Even at that position the brachialis anticus must be tightly stretched over the forward projecting trochlear surface of the humerus and badly bruised. This damage is accentuated in many cases by ignorant attempts on the part of laymen to correct matters by vigorous pulling in a straight line, thereby stretching to bursting point the already over-extended brachialis anticus. I regret to say that many medical men resort to the same procedure in the belief that traction in a straight line can do no harm if not too vigorous, and will tire out the muscles and so facilitate reduction. It is quite immaterial whether force or not is used in this procedure—the damage is due to straightening the forearm, itself a powerful lever. By the act of dislocation the forearm has been put further away, in a downward direction, from the humerus than nature ever intended. The elbow now pivots on the top of the coronoid, and straightening the arm must elongate with irresistible power the already overstretched structures in front of the joint. I have always advocated, on this account, reduction of elbow dislocations while the joint is in the flexed position, and I have not found any special difficulty in this. By grasping the upper arm with interlocked fingers the pressure of both thumbs on the olecranon will frequently reduce the dislocation without other aid than that afforded by an anæsthetic. There is, of course, no objection to traction performed at a right angle—i.e., with elbow bent.

The coronoid process forms such a large mass of bone of a low truncated cone shape that *a priori* one would not expect it to be broken in the common accidents that cause dislocation. The teachings of the class-rooms of former days die hard, and attempts to classify injuries, to facilitate teaching, frequently led to undue importance being placed in students' minds on rare or suspected injuries. Recounts of these filled up the note-book or the examination paper and gave a rounded outline to a description of the fractures met with in any one bone. The ulna has two processes—"*argal*," both had to suffer—the styloid suffered in those days not from fracture but neglect, and damage to it in association with Colles's fracture was only recognised as of frequent occurrence on the advent of the Roentgen ray. Likewise the clavicle, divided into four parts for lecture purposes—each *had* to be fractured, and the portion external to the conoid and trapezoid ligaments was credited with getting broken with ridiculous frequency and amazing deformity. The X ray here has exonerated the bone at this place from anything except a very rare longitudinal split or dislocation from the acromion.

Dublin.

LITERARY INTELLIGENCE.—New editions of Sir Malcolm Morris's "Diseases of the Skin," Sir Arthur Whitelegge and Sir George Newman's "Hygiene and Public Health," and Sir Frederick Treves's "Surgical Applied Anatomy," revised by Professor A. Keith, are announced for publication by Messrs. Cassell in September, as well as "A Manual of Physics for Medical Students," by Mr. Hugh C. H. Candy, based upon the late Mr. Frederic Page's "Elements of Physics."

TRAUMATIC RUPTURE OF ABDOMINAL VISCERA.

REPORT OF THIRTY CASES.

BY A. RENDLE SHORT, M.D., B.S., B.Sc. LOND., F.R.C.S. ENG.,
HONORARY SURGICAL REGISTRAR, BRISTOL ROYAL INFIRMARY; DEMONSTRATOR OF PHYSIOLOGY, UNIVERSITY OF BRISTOL.

Scope of report.—Included in the following list are all the cases of serious injury of the various abdominal organs that I have been able to collect from the records of the Bristol Royal Infirmary for the ten years 1900 to 1909. I have not added those brought in dead, except in one case of special interest. The total number of surgical in-patients during the same period was 21,143. I have endeavoured by correspondence to trace the after-history of the survivors, and have examined personally as many as could be brought to the infirmary.

Ruptured liver.—Eight cases, two recoveries. In three cases other viscera were injured at the same time (the pancreas, the kidney, and the spleen).

TABLE I.—*Ruptured Liver.*

No.	Sex and Age.	Year.	Operation.	Result.
1	M., 25.	1900	Five hours after injury. Abdomen full of blood. Rent large. 3¾ yards of gauze packing stuffed into the tear.	Recovered. Five months later operated on for incisional hernia.
2	M., 30.	1902	Patient came up from Avonmouth. Extensive tear. Abdomen full of blood. Packed with gauze.	Died under 24 hours.
	M., 35.	,,	None. Kidney also ruptured.	,,
4	M., 7.	,,	None. Dying.	,,
5	F., 4.	1905	None. Dying. Spleen torn.	,,
6	M., 78.	,,	None. Dying.	Died in 10 minutes.
7	F., 14.	1906	Two days after injury. Small tear of liver; spots of fat necrosis everywhere. No tear of pancreas actually seen. Nothing done.	Recovered, after a severe attack of pneumonia. Seen and examined in February, 1910. Quite well since, except one attack of abdominal pain a year before, lasting one day.
8	M., 56.	1908	Two and a quarter hours after injury. Tear 4 inches long in liver. Not much hæmorrhage. Sutured with catgut.	Died two days after.

Five cases were admitted dying, and are of little interest as regards symptoms. In three others the symptoms were as follows. (The notes are sometimes scanty and imperfect).

TABLE II.—*Symptoms in Ruptured Liver.*

No.	Injury.	General condition.	Pulse and temperature.	Pain.	Abdomen.
1	Case of glass fell on him.	One hour later, "signs of internal hæmorrhage."	Pulse at first 84, then 62. Temperature subnormal.	Much.	Distended.
7	Fell on edge of pavement.	On admission, exceedingly pale.	Temperature, 99·2° F.	Some.	Moved on respiration; slight guarding.
	—	Two days later, worse; vomiting frequently.	Pulse 128.	More.	Muscles very hard and retracted. No shifting dulness.
8	Knocked down by motor-car.	Three-quarters of an hour later, walked into infirmary. Very collapsed, however.	Pulse "slow."	Yes.	Guarding, especially over right rectus.

Ruptured intestine.—There were six cases, and of these four patients recovered.

TABLE III.—*Ruptured Intestine.*

No.	Sex and age.	Year.	Operation.	Result.
1	M., 44.	1900	None. Fractured pelvis, ruptured cæcum. Dying.	Died under 24 hours.
2	M., 18.	1900	21 hours after injury. Jejunum severely torn. Sewn up.	Died six hours later. At necropsy a second smaller rent was found in jejunum.
3	M., 50.	1901	Six and a half hours after injury. Tear ½ inch long, probably of jejunum. Sewn up.	Recovered. Subsequent history unknown.
4	M., 22	1902	Four hours after injury. No leakage of fæces. Tuberculous peritonitis present. Sewn up.	Recovered. Seen in February, 1910. Slight incisional hernia. Quite well ever since and in full work.
5	M., 31	1904	Five hours after injury. Half circumference of jejunum torn, close to duodenum. Sewn up.	Recovered. Seen in February, 1910. Quite well ever since, but mentally weak.
6	M., 16	1906	Six hours after injury. Jejunum torn right across; mesentery torn; much blood. Sewn up end to end; mesentery sutured.	Recovered. Was seen six months later; quite well.

Some general remarks will be made later. A table of the recorded symptoms in five cases follows.

TABLE IV.—*Symptoms in Ruptured Intestine.*

No.	Injury.	General condition.	Pulse and temperature.	Pain.	Abdomen.
2	Kick by horse one hour before admission.	Much collapsed; improved under morphia; later got worse.	Pulse 30, temperature 96·8. Later, pulse 80.	Yes.	Hard, retracted, very tender.
3	Struck by handle of miner's pick.	On admission, two and a half hours later, anxious appearance; retching, but not vomiting.	Pulse 80, moderate volume, soft.	Great, in paroxysms.	Hard and retracted, very tender.
4	Cycled into shaft of cart.	Soon after accident, not collapsed; after an hour or two very anxious appearance; vomited three times.	Pulse 88, good; increased to 104 in an hour.	Much.	Intensely tender and very rigid. Rent in the muscles.
5	Pole of swing boat struck abdomen.	Immediately vomited "dark stuff." Walked to tramcar. On admission, very collapsed; abdominal facies. Vomited blood (℥ii.) three times. No improvement in four hours.	Pulse 62, strong, high tension. Temperature 95°. Four hours later, pulse 70, temperature 97°.	Much.	Did not move with respiration. Very tender and rigid; retracted.
6	Block of crane fell on him.	On admission, was concussed; not very collapsed. Four hours later, paler, collapsed.	Pulse 100. Temperature 97·8°. Four hours later, pulse 130.	Much.	Upper part moved on respiration. Very rigid and tender, especially in hypogastrium. Dulness over pubes and left Poupart's ligament.

Ruptured pancreas.—Two cases; one recovery. One of these has already been described under the heading of ruptured liver (Case 7, Table I.). The injury to the pancreas was not actually found, but was diagnosed on the evidence of fat necrosis, scattered throughout the subcutaneous, subperitoneal, and intra-abdominal adipose tissue. This case was operated on two days after the injury, but nothing was done. She nearly died from pneumonia a few days afterwards, but eventually recovered. I saw her in February,

1910, when she was perfectly well. There had been one attack of acute abdominal pain.

The other case, a boy, aged 12 years, was admitted in 1907, shortly after having been run into by some trucks. He was very collapsed, vomiting, and in considerable pain. The pulse was 99 and the temperature 97·4° F. The abdomen was very rigid and tender. Being watched for some hours, his condition became more alarming, though details are not given. Laparotomy was performed; the pancreas was found torn right across and there was much effusion of blood coming from the lesser sac. Two arteries were found and tied. The rent in the pancreas was plugged with gauze. He did well for a while, then developed pneumonia of both bases after one week. The edges of the wound appeared softened and digested. Eventually he became noisy and delirious, with irregular fever, and died from gangrene of the lung three weeks after the injury. At the necropsy there was a large subphrenic abscess under the left dome of the diaphragm communicating with the tear in the pancreas, and a good deal of tissue digestion.

These two cases are very characteristic of the types of clinical picture described in the literature as following injury of the pancreas. Pneumonia, fat necrosis, and subphrenic abscess are all frequent.

Ruptured spleen.—Three cases; all of them were fatal.

TABLE V.—*Ruptured Spleen.*

No.	Sex and age.	Year.	Operation.	Result.
1	M., 33	1903	Seven hours after injury. Great internal hæmorrhage; large rent of spleen. Splenectomy.	Died under 24 hours.
2	M., 24	1905	Seven or eight hours after injury. Huge internal hæmorrhage; spleen in two pieces. Splenectomy.	Died nine days after.
3	F., 4	1905	Admitted dying two days after injury. No operation.	Died under 24 hours. Rupture of liver and spleen found post-mortem.

TABLE VI.—*Symptoms in Ruptured Spleen.*

No.	Injury.	General condition.	Pulse and temperature.	Pain.	Abdomen.
1	Crushed by wheel of cart.	Condition on admission did not give rise to anxiety. No notes.	—	—	—
		Six hours later, pale and collapsed.	Very weak pulse.	Yes.	Dull on left side. Splash over præcordial area.
2	Fork of bicycle broke.	Immediately after injury seemed all right.	Pulse 90, good volume.	None.	No tenderness or rigidity.
		Six and a half hours later, very collapsed; intensely white.	Pulse 98, weak. Temperature 95°.	Yes.	Full, rigid, not tender.

Ruptured kidney.—Six cases; three recoveries. In one of the fatal cases the liver was also ruptured. In another the pelvis of the kidney was torn by the injury, and in the course of months following a saccular distension took place. The fatal result was brought about by the performance of a nephrectomy. A large number of patients whose only symptom was a transient hæmaturia have not been included in the list.

Ruptured bladder.—Five cases; only one recovered. In this case, the pelvis was also fractured. Four were intraperitoneal ruptures; in the other case the bladder was torn completely away from the urethra. In one case there was apparently no injury; the patient was in a drunken sleep, and was awakened by the pain of the rupture. No stricture and no ulceration of the bladder were found. This occurrence, though very unusual, is not unique.

TABLE VII.—*Ruptured Kidney.*

No.	Sex and age.	Year.	Condition and treatment.	Result.
1	M., 21	1900	Admitted in October, 1899, for "? ruptured bladder," after fall from ladder; no operation.	—
			Admitted later for recurring lump in abdomen associated with hæmaturia, which proved to be a saccular bulging of the pelvis of the right kidney. Drained from in front. Finally, lumbar nephrectomy was performed. The kidney was reduced to a mere shell.	Death from shock, eight months after injury.
2	M., 20	1901	Pain, fever, vomiting, hæmaturia, tender mass felt in left loin, diagnosed as perirenal hæmatoma. Treatment: rest.	Cured. Seen and examined in February, 1910. Quite well ever since. Successful cricketer.
3	M., 16	,,	Collapse, vomiting, mass in left loin diagnosed as perirenal hæmatoma; hæmaturia. Treatment: rest.	Cured. Wrote in February, 1910, to say that he has been perfectly well since.
4	M., 35	1902	Ruptured liver and kidney. Dying. No operation.	Died under 24 hours.
5	F., 25	1906	Fell down four days before admission. Admitted collapsed, with large swelling in loin. Operation: perirenal hæmatoma found; kidney ruptured and full of blood. Nephrectomy.	,, ,,
6	M., 51	1908	Hæmaturia. Swelling in loin. Treatment: rest.	Cured. Seen in February, 1910. Perfectly well ever since.

TABLE VIII.—*Ruptured Bladder.*

No.	Sex and age.	Year.	Operation.	Result.
1	F., 4	1901.	On the evening after the day of injury. Abdomen opened above pubes; bladder found completely torn away from urethra; urine in peritoneal cavity. Fractured pelvis. Bladder opened and drained above pubes; catheter put in.	Died next day.
2	M., 24	1902	One week after injury. Abdomen opened; at least 13 pints of urinous fluid in peritoneum. Intraperitoneal rupture of bladder. Rent sewn up; catheter passed and left in.	Died two days later.
3	M., 38	1905	Several hours after probable time of rupture; the subcutaneous tissues in front of the bladder were explored on the theory of extraperitoneal rupture and none found. Seven or eight hours later abdomen opened; intraperitoneal rent found and sewn up; catheter tied in.	Died immediately afterwards.
4	M., 75	1906	About six hours after injury. Abdomen opened; intraperitoneal rent of bladder found and sewn up; catheter tied in.	Died under 24 hours.
5	M., 31	1909	Ten hours after injury. Abdomen opened; intraperitoneal rupture of bladder; torn by splinter of a fractured pelvis. Rent sewn up; catheter tied in.	Recovered. Seen in January, 1910. Some pain over the site of fracture. Mild cystitis; no other bladder trouble.

A table of the symptoms in each of the five cases is appended. Some general remarks are made in the summary at the end.

TABLE IX.—*Symptoms in Ruptured Bladder.*

No.	Injury.	General condition.	Pulse and temperature.	Abdomen.	Bladder.
1	Run over by train.	Seen soon after; sent home; no pain; facies normal.	Pulse quiet.	Soft.	Could not pass urine that night.
		Next day, in out-patient-room, was pale and anxious-looking, in great pain; admitted. Symptoms increased later in the day; vomiting.	Pulse 148, small.	Distended, rigid; dull in flanks.	No urine passed. Only blood withdrawn by catheter. Fluid injected did not all return.
2	Fell into ditch when drunk, one week before admission.	On admission, little or no pain. Did not appear very ill.	Pulse 88, small, regular. Temperature 98°.	Tense, greatly distended, not rigid; dull in flanks. Œdema of skin.	Had been passing urine sometimes and using catheter sometimes.
3	Bladder ruptured whilst asleep, drunk. No obstruction.	Admitted some hours after. Looked ill; much pain.	Pulse 120, temperature 98°.	Distended; very tender; rigid in hypogastrium. Effusion into abdominal wall.	Only blood by catheter. Thought to be surgical emphysema of rectum.
4	Ashes fell on him.	Admitted soon after. Very collapsed; great pain.	Pulse not palpable.	Tender in hypogastrium. Rigid.	(No notes.)
5	Immense stone fell against him, and pinned him down.	(No notes.) Admitted eight hours after.	—	Distended, tender, bruised.	(No notes.)

Ruptured inferior vena cava.—A boy, aged 10 years, was brought in dead in 1906, having been knocked down by a vehicle in the street. Death was almost instantaneous. At the necropsy there was a rent one-third of an inch long, obliquely placed, in the inferior vena cava just below the pancreas. There was a little blood (3 oz.) in the peritoneal cavity. This was the sole injury. The condition must be very rare, if not unique.

Ruptured mesenteric or omental vessels.—A boy, aged 12 years, was admitted in 1908, presenting symptoms of internal hæmorrhage after a fall on the abdomen. An operation was performed and a blood effusion found, but no source could be discovered. He got well.

General Conclusions.

These remarks may be classified under the headings of Diagnosis and Prognosis.

Diagnosis.—The great outstanding lesson is to enforce the need for cautious and patient observation after any abdominal injury, especially if it is of such a nature that the blow might be unexpected or severe. Above all, no favourable opinion must be based solely or principally on the rate or character of the pulse. Excluding cases admitted moribund, out of ten patients with ruptured liver, intestine, pancreas, or spleen, the pulse-rate when they were first seen was in one case 100, in another 99, and in seven about normal. In one it was only 30. *In every case of rupture of any abdominal viscus in which the pulse-rate on admission exceeded 100, the patient died within 24 hours.* It is often mentioned that the volume and tension were good. The text-books usually state that the pulse-rate will rise if there is a serious injury. This was true in at least six cases, but in one of ruptured liver it fell from 84 to 62.

The temperature seems to be of more value. It is only recorded in the notes nine times; in five of these it was markedly subnormal. Pallor or anxious appearance is often remarked upon. Abdominal pain and rigidity were almost constant, except in the tragic and deceptive cases shortly to be narrated. Vomiting was not usual. Only one patient vomited blood. The diagnosis was usually made by observing that after some hours the appearance, the abdominal condition, and the pulse did not improve; in many there was a decided change for the worse.

Several cases illustrate well the extraordinary way in which the patient may come up with few or no alarming symptoms after a mortal injury. A girl (Case 1, Table VIII.) whose bladder was torn completely away from the urethra, and whose pelvis was fractured, was seen soon after the injury in the casualty room; the appearance was normal, the pulse slow and of good volume, and the abdomen soft. It was not until she came up with an out-patient note on the following day that a diagnosis was made.

A man (Case 2, Table VIII.) fell into a ditch whilst intoxicated and ruptured his bladder into the peritoneum. He did not come to the infirmary for a week. During that time he saw his medical man, who passed a catheter several times; often he could pass urine himself. He was up and about part of the time. On admission his abdomen was immensely distended; at the operation at least 13 pints of urinous fluid was evacuated, and 12 sutures were needed to sew up the rent in the bladder.

The report further illustrates the deadly nature of injury to the spleen, on account of the frequency with which it passes unrecognised. Both the cases recorded were, when first seen, apparently little the worse for their hurt, though about six hours later both were in a dying condition. It cannot be too thoroughly impressed upon the new generation of medical men that all cases of unexpected or possibly severe blows on the abdomen must be watched for several hours, however good the pulse may be, before they can be regarded as safe.

Prognosis.—It will be observed that there is an excellent series of recoveries after ruptures of the intestine, and several after severe injuries of the kidney, but that only one here and there is saved after other abdominal injuries. It is gratifying to find, however, that those who survive the immediate trouble seem to do well afterwards. Two got small incisional hernias. Apart from these the writer has seen or heard from one case of ruptured liver and pancreas, two cases of ruptured intestines, three of severe injuries of the kidney, and one of ruptured bladder. Each gave a gratifying account of subsequent progress, and all were as well and strong as ever they were, with the exception of the last. An exception must be made in regard to ruptures of the pancreas. Both cases got pneumonia, and one died several weeks later of a subphrenic abscess and gangrene of the lung.

Clifton, Bristol.

CHRONIC OBSTRUCTION OF THE BOWEL IN A HYDROCEPHALIC IMBECILE; RESULTS AT POST-MORTEM EXAMINATION.

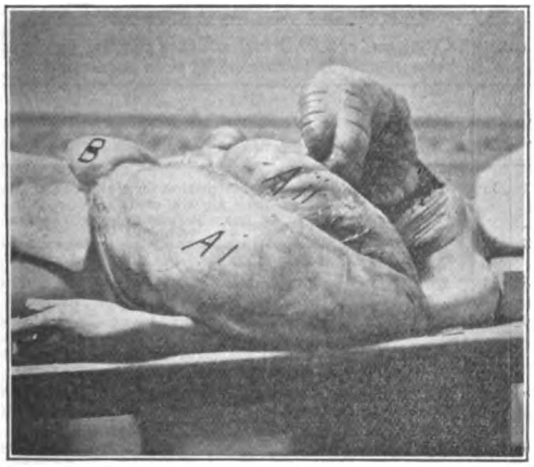
BY A. L. E. F. COLEMAN, M.B., CH.B. ABERD.,
AND
H. D. EVERINGTON, M.B. LOND., M.R.C.S. ENG., L.R.C.P. LOND.

A MAN, aged 28 years, was admitted into the Croydon General Hospital, under the care of Dr. John Wayte (by whose kind permission these notes are published), on May 11th, 1909, with symptoms of obstruction. The history of the case showed that the patient, an imbecile, had always had difficulty in getting his bowels to move. The difficulty was becoming greater and he became "stouter and stouter." Pain began to be complained of, but medical advice was not sought until the day of his admission into hospital. He was hydrocephalic and the legs were paralysed, but he had been able to crawl about and had seemed fairly happy.

On examination the abdomen was found to be enormously distended. It was resonant in places, but for the most part was dull, and a hard mass 8 or 9 inches broad could be felt in the middle line. The patient complained but little of pain in spite of the obviously serious condition. Enemata of turpentine and gruel were begun, and after three injections a small motion was passed. Castor oil in small repeated doses was administered, but neither of these measures availed,

and the patient gradually sank and died at 9.40 A.M. on the 13th.

Necropsy.—The abdomen measured 52 inches at its greatest circumference, and on being incised the tissues began to tear owing to the internal pressure, showing that the muscular walls had not entirely accommodated themselves to the swelling, and that the condition was therefore to some extent acute. On opening the peritoneum a hollow viscus at once protruded and had to be punctured to prevent its bursting. The abdomen was then completely laid open and the front wall of the chest was removed. What appeared to be an enormous stomach was then seen, extending from the level of the third rib above down into the pelvis. The heart was not to be seen, and the lungs could just be detected at the sides; the diaphragm was completely displaced. The viscus mentioned proved to be an immensely dilated sigmoid flexure and rectum, terminating on the one hand (A ii) in the lower end of the descending colon, and on the other (A i) at the anus. The length of this loop of intestine was 45 inches and its greatest circumference 23 inches. On laying it open it was found to contain nearly 3½ gallons of fæces of a clay-like consistence and dark brown colour. The walls of the sac were very thick and the vessels exceedingly large, as may be seen from the illustration. The rest of the large bowe



Reproduction of a photograph showing immensely distended sigmoid flexure and rectum.

was somewhat distended with gas and measured at its greatest circumference 17 inches, but beyond this increase in size it was normal. The small intestine and stomach appeared to be normal. The bladder was entirely covered by peritoneum and was pedunculated, as appears in the illustration in the right groin at B. The chief point with regard to the other organs was the small size of the lungs—13 oz. each—and these were compressed into a small space at the apex of each side of the thoracic cavity. The skull measured 26 inches in the occipito-frontal diameter; the fontanelles were closed, but the bone was everywhere thin. The ventricles of the brain contained over a pint of clear fluid.

This case well illustrates how greatly the wall of the large bowel may be stretched and its lumen increased in chronic constipation, and to what extent the abdominal parietes will accomodate themselves to the altered conditions. That such a condition could arise without the greatest distress and pain can only be accounted for by the fact that the patient was an imbecile.

PRESENTATION TO A MEDICAL PRACTITIONER.—At the town-hall, Ottery St. Mary (Devon), on August 21st, Sir John Kennaway, on behalf of a large number of subscribers, presented Mr. Felix P. Bartlett, L.R.C.P. Lond., M.R.C.S. Eng., D.P.H. Lond., with a silver salver as a mark of respect and esteem on the occasion of his leaving Ottery St. Mary for Australia. Mrs. Bartlett received a rose-bowl.

THE OPERATIVE TREATMENT OF RETROVERSION AND PROLAPSE OF THE UTERUS.

BY ALBERT E. MORISON, F.R.C.S. EDIN.,
SENIOR SURGEON, HARTLEPOOLS HOSPITAL; SENIOR ASSISTANT SURGEON, SUNDERLAND INFIRMARY.

PROLAPSE of the uterus occurs from the following causes: (1) Tearing or stretching of the posterior segment of the pelvic floor, which consists chiefly of the levator ani and the deep pelvic fascia; (2) increased intra-abdominal tension and alteration in the line of projection of the intra-abdominal pressure; and (3) stretching of the parts forming the anterior segment of the pelvic floor. In the early stages of prolapse one or all of these causes may be at work, in the later processes all are involved.

A short description of the normal conditions of the pelvic cavity will help in understanding this. In the natural condition of the pelvic cavity the uterus in the erect position of the body, and with the bladder entirely or almost empty, lies somewhat anteflexed upon the bladder, and when pressure is put upon the uterus by any increase of intra-abdominal tension the direction in which it is exerted is at a right angle forwards and downwards and tends to still further antevert the uterus. When the bladder is full the uterus is pushed backwards, and any increase in the intra-abdominal pressure tends to aggravate the condition. In this position a stretching of the anterior pelvic segment takes place, and the backward pressure may become such that a permanent retroversion or retroflexion is produced. These two factors of themselves will, however, not cause prolapse unless the third factor be weakened or destroyed—viz., the posterior segment of the pelvic floor. This, as we have seen, consists of the levator ani and the fascial planes constituting the perineal body. Under increased intra-abdominal pressure this body contracts to oppose the effect of the contraction of the abdominal muscles and closes the outlets of the pelvis, the rectum, and vagina during this period of strain. When the perineal body is torn or stretched not only does this counteracting force disappear, but the angle at which the force from above is directed is changed. Instead of being downwards and forwards, it now becomes downwards and partially backwards. When the force acts in this manner on a relaxed posterior segment, and especially on an enlarged and flabby uterus such as is present after parturition, first retroversion, then complete descent of the pelvic contents, takes place.

The sequence of events is, then, as follows:—A torn perineum with stretching of the utero-sacral ligaments and vesico-vaginal septum, together with a large, flabby, sub-involuted uterus, allows any increased intra-abdominal strain, such as lifting, &c., to produce a prolapse more or less complete.

Any operation, therefore, undertaken to cure this condition must aim at three things: (1) Restoration of the perineal body; (2) replacement of the uterus to its normal position, so that the intra-abdominal pressure is again exerted in the normal direction—viz., downwards and forwards; and (3) improvement of the condition of the anterior uterine segment.

As many of these cases of procidentia occur in women who have not passed the menopause, a further important desideratum is that the possibility of conception shall not be interfered with, and in the event of pregnancy that the patient shall not incur any special risks during parturition. All operations which have as their result the fixing of the uterus to the anterior abdominal wall are to be condemned. Not only may this suspension interfere with the natural course of pregnancy, but post-partum hæmorrhage is said commonly to follow labour when the uterus is thus fixed. Moreover, the adhesions formed are apt to stretch and to produce a band between the uterus and the anterior abdominal wall which may be a source of danger as the incarceration of a loop of intestine under it can occur.

The operation I am about to describe obviates, I think, all these disadvantages, and is easy to perform. The time occupied in the whole operation need not exceed half an hour and no special instruments are required. Since my first operation in June, 1909, I have operated on 25 cases varying in age from 20 to 73 years, and all have

been successful both as to the operative result and subsequently. The preparation of the patient for the operation is similar to that for any pelvic operation by the combined abdominal and perineal route. The patient stays in bed for at least two days before the operation. Her vagina is douched twice a day with 1 in 2000 sublimate lotion; a dose (ʒi.) of castor oil is given two nights before the operation; on the evening preceding the day of operation a hot bath; and on the operation morning a simple enema is administered. Two hours before the time fixed for operation the abdomen and vulva are shaved dry and painted with tincture of iodine (B.P.) and the parts are covered with a sterile towel. The patient is first nearly anæsthetised with chloroform, and ether by the open method is given during the remainder of the operation. The patient is placed in the lithotomy position for perineorrhaphy and the abdomen, vulva, and vagina are again painted with tincture of iodine. I invariably do the flap-splitting operation devised by Lawson Tait, making the alteration in the technique of stitching the raw surfaces together in layers with buried catgut sutures. A Pezzer retaining catheter is inserted into the bladder and remains for a week; the vagina is plugged with a gauze tampon powdered with boric acid, and the patient is then transferred to the Trendelenburg posture. Surgeon and assistants meanwhile put on fresh sterile gloves before undertaking the abdominal part of the operation. The parietal incision is made in the middle line, the lower end reaching the pubes below. After opening the peritoneum the pelvic contents are examined; the uterus is grasped with forceps and pulled upwards. The intestines are then packed off afterwards with gauze mops. Each round ligament is seized with clip forceps about its centre. Another pair of forceps is passed through each broad ligament close to the uterus and 1 to 2 inches below its superior margin, care being taken to avoid the veins of the pampiniform plexus. The round ligaments are now caught in the forceps, passed through the broad ligaments, and drawn through the latter until their loops meet behind the uterus. A strong silk suture is passed through them, including the back of the uterus, and is tied. In severe cases of prolapse a second suture is inserted in the same way an inch lower down to obtain a broader sling from which the uterus hangs. The position of the uterus is now entirely changed. It is raised high up in the pelvis, anteverted, and lying on the bladder. The broad ligaments are tightened up by the passage of the round ligaments through them; the utero-sacral ligaments are also drawn upwards, and both anterior and posterior vaginal walls are tightened. As soon as the patient is released from the Trendelenburg position the intestines fall down into Douglas's pouch, and this should be seen before closing the abdomen. The abdominal wall is sutured in tiers, the wound is painted with iodine and dressed with aseptic gauze and wood-wool wadding.

After-treatment.—The vaginal tampon is removed in two days, after which a douche of 1 in 5000 sublimate lotion is given night and morning. A simple enema is administered every day. The Pezzer catheter remains in the bladder for a week and urine is allowed to escape at six-hourly intervals by removing the plug in the end of the catheter. During this time large quantities of distilled water (half a gallon per day) should be drunk by the patient to prevent the deposit of salts on the catheter from the urine. No restriction is made as to the position the patient may select as she lies in bed, where she remains for three weeks.

The after-history in all of the cases on which I have performed this operation is excellent. No bladder trouble such as might be expected is complained of, the patients being able to retain their urine for as long as eight hours.

One patient (Case 4) returned complaining of "something coming down," but examination showed the uterus to be high up in good position. There was, however, a slight prolapse of the anterior vaginal wall, but the bladder was not affected, and this was rectified by removing an elliptical portion of the mucous membrane. In this case the prolapse was of many years' standing, and the vaginal mucous membrane was very much thickened from exposure and friction on the patient's thighs.

Appended herewith is a list of all the cases I have operated on up to the end of last year. As none of these patients have become pregnant since the operation I have had no opportunity of recording the behaviour of the uterus during this period and subsequently. It is not too much to hope that the round and broad ligaments with their muscular and elastic tissue will accommodate themselves to the growing requirements of the enlarging uterus and return to their normal condition when it has emptied itself, as we know these ligaments do in the normal state.

TABLE I.—*Cases of Retroversion of the Uterus for which Suspension only was performed.*

Case.	Age.	Date of operation.	History.
1	42	6/1/10	No children. Dysmenorrhœa. "Bearing-down" pains. Uterus retroverted and enlarged.
2	29	5/4/10	Ill for nine months. Three children. Youngest 3 years. Metrorrhagia and dysmenorrhœa. Uterus retroverted and enlarged.
3	20	16/8/10	"Pain and falling of the womb." No children. Frequent micturition. Uterus retroverted and pushed down. Cystic swelling in Douglas's pouch size of goose's egg. Right cystic ovary removed. Uterus suspended.
4	37	18/11/10	Three children, youngest 6. Metrorrhagia and menorrhagia. Uterus retroverted and enlarged (4½ in.).
5	39	21/11/10	No children. Menorrhagia and dysmenorrhœa. Uterus retroverted and enlarged.
6	24	—	—

TABLE II.—*Cases of Prolapse of the Uterus for which Suspension and Perineorrhaphy were performed.*

Case.	Age.	Date of operation.	History.
1	35	30/6/09	Frequency of micturition for eight years. Complete prolapse for six years. Four children, youngest 3 years. Perineum torn to rectum.
2	35	23/7/09	Complete prolapse for two years. Four children, youngest 4 years. Perineum ruptured.
3	38	28/7/09	Complete prolapse since birth of last child two years ago. Perineum torn.
4	42	31/8/09	Complete prolapse for 14 years. Cervix very elongated. Four children, youngest 9. Perineum torn. Subsequent colporrhaphy for prolapse of vaginal mucosa.
5	43	11/11/09	Slight prolapse and cystocele. Four children, youngest 9. "Bearing down" and frequency of micturition. Perineum torn.
6	35	10/1/10	Slight prolapse and retroversion. Menorrhagia. Frequent desire to micturate. Three children, youngest 18 months. Perineum torn.
7	67	23/1/10	Complete prolapse for 20 years. Uterus constantly outside vulva.
8	35	24/2/10	Two children, 6 and 1¾ years. Perineum torn at first confinement. Uterus prolapsed slightly after this; completely since last child was born.
9	42	19/4/10	Seven children, youngest 5. Complete prolapse for seven years. Perineum torn.
10	42	11/5/10	Six children, youngest 7. Complete prolapse for some years. Perineum torn into rectum.
11	28	1/6/10	Three children, youngest 2. Has had "bearing down" since birth of last child. Complete prolapse. Perineum torn.
12	73	16/6/10	Ten children, youngest 32. Complete prolapse for many years. Patient unable to go about.
13	32	24/6/10	Complete prolapse since birth of last child eight years ago. Frequency of micturition. Perineum torn.
14	56	26/8/10	Six children, last 18 years ago. Constant desire to micturate. Complete prolapse for several years. Perineum torn.
15	39	28/8/10	Six children, youngest 5. Complete prolapse for three years. Perineum torn.
16	24	24/9/10	One child, 18 months ago. Large cystic swelling in Douglas's pouch. Uterus retroverted and prolapsed, but not outside vagina. Small ovarian cyst removed from left side. Uterus suspended. Perineorrhaphy.
17	38	28/9/10	Ten children, last seven weeks ago. Uterus prolapsed for four years. Perineum badly ruptured.
18	30	3/10/10	Three children, youngest 11 months. "Falling of womb" for two years. Perineum torn at first confinement.
19	26	2/11/10	Three children, youngest 2. Has had a "bearing down" since birth of first child. Complete prolapse. Perineum torn.

Sunderland.

PHTHISIS IN WALES.

BY HUGH R. JONES, M.A., M.D. CANTAB., B.SC. LOND., D.P.H.

IN the Registrar-General's report for 1909, corrected death-rates are published for the quinquennium 1905–09, for 18 counties in which the highest mortality from phthisis was recorded. (Table I.) Ten of the 18 counties were Welsh, and in six of them the mortality was higher than in any English county. Yet the death-rate from phthisis in Wales has fallen fully 37 per cent. during the last 25 years—from 2·04 per 1000 in 1881–1890 to 1·28 in 1900–09, while that in England and Wales fell 33 per cent.—from 1·77 in 1881–1890 to 1·19 in 1900–09.[1]

TABLE I.—*Corrected Phthisis Death-rates per Million.*

Phthisis 1905–09.	Persons	Males	Females

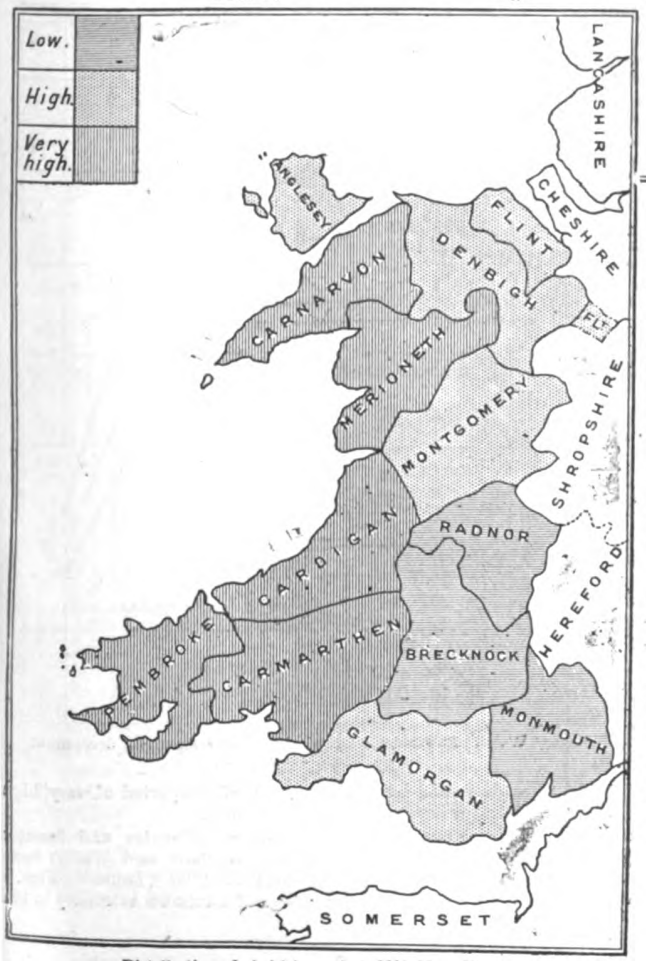
Glamorganshire	1134	1122	1145

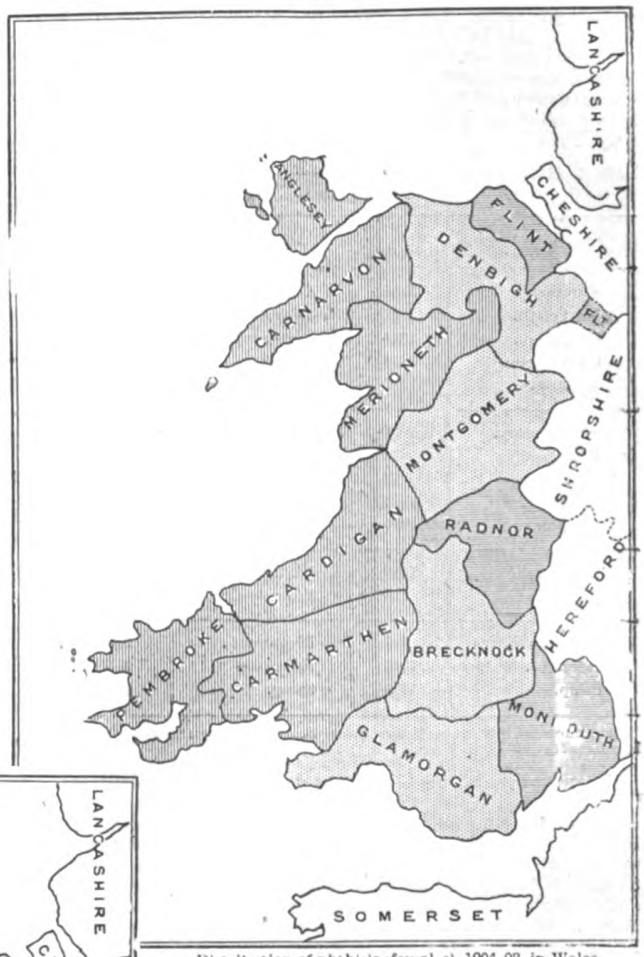
[1] Crude death-rates are quoted unless otherwise stated.

FIG. 1.



Distribution of phthisis (males), 1904–08, in Wales.

FIG. 2.



Distribution of phthisis (females), 1904–08, in Wales.

The mortality of males in Wales is, however, less than that in the whole country—1·30 per 1000 compared with 1·40 for the decennium 1900–09—notwithstanding that it was in excess in 5 out of the 12 Welsh counties. It is intermediate between the mortality in the urban and rural counties. It must be remembered that there are no unhealthy industries in Wales, and that two of the chief occupations—viz., mining and agriculture—are favourable to a low mortality from phthisis, while the mortality in a third—stone and slate quarrying—though twice as high as in the others, is not much above the average, the comparative mortality figures being for all occupied males, 175; coal-miners (South Wales and Monmouthshire), 93; stone and slate quarries, 186; and agriculturists, 79. The recorded mortality of males cannot therefore be regarded as satisfactory.

On the other hand, the mortality of females is very much higher than in the whole country (being 1·27 per 1000, compared with 0·99), with the result that the phthisis mortality of both sexes in Wales exceeds that for England and Wales by 0·09 per 1000. The female mortality in Wales is lower than the male mortality only by 2·3 per cent., while for the whole country it is lower by more than 29 per cent.

If the statistics of South and North Wales be compared it is seen that while the mortality of

England and Wales	1362	963
South Wales	1215	1260
North Wales	1407	1261

females is nearly the same in both divisions, the male mortality is appreciably higher in North Wales than in South Wales. (Table II.)

The counties with the highest mortality—both male and female—are situated on the west littoral, those with the lowest mortality on the English border, and the mortality in the intervening counties is intermediate. (Table III., Figs. 1 and 2.)

Salop.	1076	Salop.	863

Reference to the maps shows how the mortality from phthisis increases from East to West.

Coincidently with the fall in the death-rate from phthisis in England and Wales, the age of maximum mortality from phthisis has been postponed both in males and in females. In 1851–60 the maximum male mortality occurred between the ages of 20 and 25 years, in 1861–70 between the ages of 35 and 45 years, and in 1891–1900 between the ages of 45 and 55 years. The maximum mortality among females in 1861–90 was between the ages of 25 and 35 years, and in 1891–1900 between the ages of 35 and 45 years.

In Wales a sustained high mortality of males between the ages of 20 and 65 years was recorded in the three decennia 1881–90, 1891–1900, and 1900–09 (Table IV., Figs. 3 and 4);

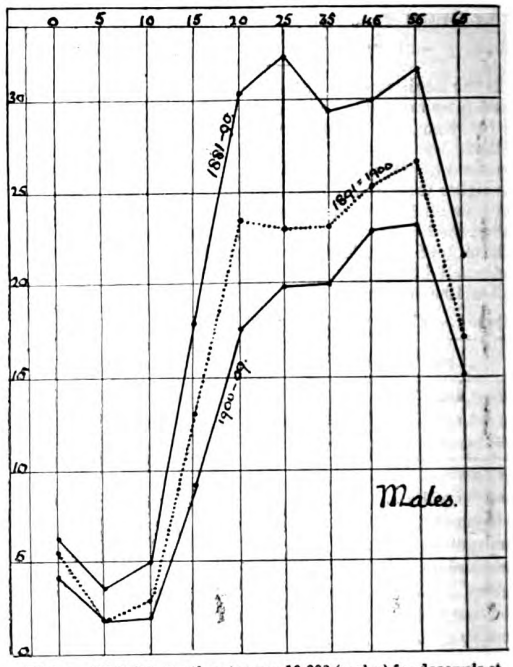
The 1900–09 figures supplied by the Registrar-General.

but a similar postponement of the age of maximum mortality is observed—from the age-period 25–35 in 1881–90 to the 55–65 period in the last two decennia. Among females the mortality rose to a maximum at the age-period 25–35 in the three decennia, but the duration of the period of very high mortality is shorter than among males.

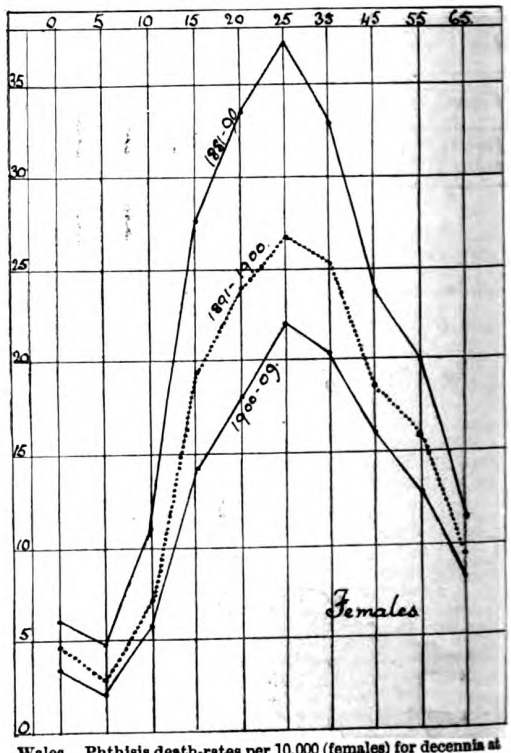
For comparison, the death-rates of males and females (North Wales, South Wales, and England and Wales) have been charted for the decennium 1891–1900. (Table V., Figs. 5 and 6.) Except for the earlier age of maximum mortality in the

FIG. 3.



Wales. Phthisis death-rates per 10,000 (males) for decennia at age-periods.

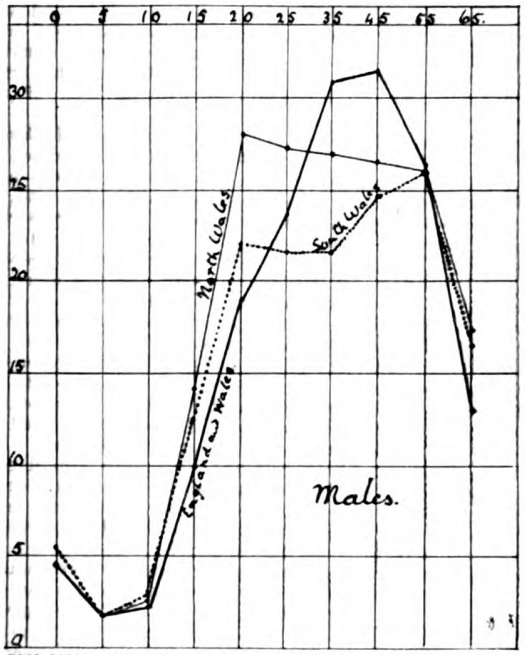
FIG. 4.



Wales. Phthisis death-rates per 10,000 (females) for decennia at age-periods.

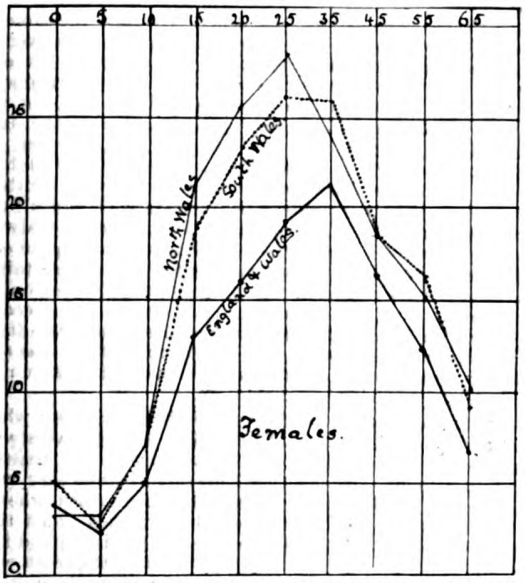
Welsh divisions, the three curves of female mortality are very similar in form. The curve for South Wales shows that the age of maximum mortality is being postponed. The curves of male mortality in the Welsh divisions differ materially in form from the curve for England and Wales. In North Wales the age of maximum mortality is 20–25 years, and a high rate of mortality is maintained until the 55–65 age-period.

FIG. 5.



1891–1900. Phthisis death-rates per 10,000 (males) at age-periods.

FIG. 6.



1891–1900. Phthisis death-rates per 10,000 (females) at age-periods.

In South Wales a similar period of high mortality is recorded, but the maximum mortality occurs at the 55–65 age-period. In England and Wales the mortality from phthisis increased to a maximum at the 45–55 age-period. At the earlier age-periods it was lower than the mortality in Wales, but in the 25–35 age-period it exceeded that of South Wales, and in the next age period that of North Wales also. The discussion of the significance of the differences in the age incidence of phthisis must be deferred until the county statistics for the last decennium are published.

Liverpool.

NOTES ON THE CLINICAL APPEARANCES IN TWO CASES OF CEREBRAL DISEASE,

ONE BEING GRAVE ORGANIC DISEASE AND THE OTHER PURELY FUNCTIONAL.

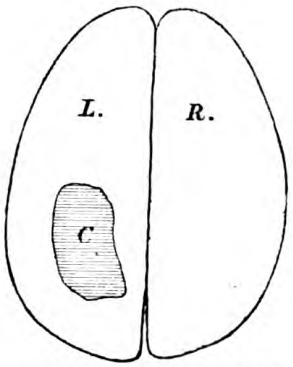
BY JOHN H. AYTOUN, M.B., C.M. EDIN.

MY reason for publishing the two following cases is to show the resemblance which a case of grave organic disease of the brain may bear to one of purely functional disease of that organ; and also to show the difficulty which may exist in general practice in making a diagnosis in such cases. In both cases a correct diagnosis was made, but in neither of them could it be made for at least several hours from the time that they were first seen.

CASE 1.—The patient was a female, aged 29 years, born in the North of Scotland. Her mother had died at an advanced age. Her father, when I first saw her, was still alive and in fair health at the age of 60 years. Two of her father's brothers had died from apoplexy with paralysis, in each case the attack beginning after the age of 40 years. The patient had never been very robust. Some years before the attack for which I attended her she fell, injuring the dorsal region of her back. This part subsequently had the actual cautery applied. Since then she had always worn a poro-plastic support round the chest. She was a person of considerable intelligence, earning her living by acting as a housekeeper, but her work was light. She took her meals quite regularly and was strictly temperate. For some months before her attack she had become most religious and had attended a number of missionary and other religious meetings. During this time, also, she often complained of a feeling of weakness and of breathlessness on exertion. It was noticed that she was unusually pale. Her employer said that for a week before her attack she was "queer." She seemed, however, to be in her usual spirits, and on the evening before her attack she went with her employer to call on some friends. On the day before her attack she told her employer that she had a peculiar sensation in her right arm. On the morning of her attack she got up as usual, made breakfast, and took some herself. After breakfast she went on with her ordinary work. Very soon she complained to a neighbour of feeling ill, and said that the left side of her head (pointing to the temporal region) was very painful. She was immediately put to bed in her clothes. She vomited a small quantity of bile-stained frothy liquid—the vomiting being accompanied by a considerable amount of gurgling in the abdomen. She moved about uneasily in bed and moaned frequently. At 10 A.M. I saw her for the first time; this was an hour after she became ill. She was lying in bed in her clothes, slightly on the right side. Her face was very pale. She rolled about in bed a little, and occasionally vomited a small quantity of mucus. Her eyelids were quite closed. On raising the eyelids the pupils were seen to be of equal size and neither

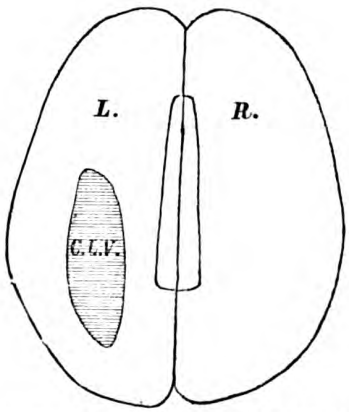
markedly dilated nor contracted. The conjunctival reflex was present on both sides. I noticed that on touching the left conjunctiva, in addition to spasmodic closure of the eyelids, there was also a marked drawing up of the angle of the mouth on the left side. The pupils reacted to light. On attempting to pass a finger into the mouth the teeth became violently clenched and the head was turned to the right side. I noticed that she was "unwell," and that the rectum was empty. The pulse was 84 per minute, regular, and of moderate force and volume. The vessel walls seemed to be healthy. The respirations became periodically slightly stertorous for a minute or so and then this symptom passed off. The temperature in the axilla was 97·8° F. Both legs and arms were quite flaccid and fell down when raised. Both knee-jerks were normal and no ankle clonus was present on either side. She could swallow, with some difficulty, a teaspoonful of milk when put into the mouth, but seemed to be quite unconscious. At 1 P.M. the patient's condition was very similar. There was slight retching of mucus occasionally. The teeth were still tightly clenched whenever a teaspoonful of milk was attempted to be poured into the mouth. No urine had been passed. At 7 P.M. the temperature was 101° and the pulse 150, small, and could only be counted with difficulty. The breathing was now stertorous, the face

FIG. 1.



Horizontal section of the brain at the level of the centrum ovale minus, showing clot in brain substance, C.

FIG. 2.



Horizontal section of the brain at the level of the centrum ovale majus, showing clot in the left lateral ventricle, C.L.V.

was still very pale, the eyelids were still closed, and the pupils continued equal, but did not react to light. The conjunctival reflex was entirely absent on the right side, and very slightly present on the left side. The teeth were still clenched. The left arm and leg were now both in an extended position and in a state of tonic rigidity, while the right arm and leg were flaccid, as if paralysed. In half an hour the conjunctival reflex was totally abolished on both sides. The face became livid, breathing more stertorous, and the patient died the same night.

Post-mortem examination.—On removing the calvarium the posterior half of the left cerebral hemisphere was seen to be bulged in a very marked manner. On horizontal section, exposing the centrum ovale minus, a large mass of dark clotted blood was seen to occupy the posterior and outer part of the left cerebral hemisphere. On making a similar section exposing the centrum ovale majus, a continuation of the same clot was seen, somewhat further from the surface and more elongated antero-posteriorly. It extended into the left lateral ventricle, which was much distended with blood-clot. The total weight of the clot I estimated to be from 3½ to 4 oz. I append diagrams showing the situation and shape of the clot as seen on sections of the brain. The right side of the brain showed no sign of any abnormality.

CASE 2.—Three weeks after the occurrence of Case 1 I was sent for in the morning to see a girl who had become unconscious. The history I got was that the patient, aged 18 years, had always been a strong healthy girl, and, as far as could be gathered, her family history was very good. She was accustomed to hard work. Early in the morning of the day that I was sent for she had become "unwell." She had got up as usual, and was going on with her work when she suddenly uttered a cry and fell on the floor, giving her head rather a hard knock and becoming apparently unconscious. She was carried to bed with her clothes on and was kept quiet. I saw her an hour after this occurrence and found that she was lying on her back in bed with her eyelids slightly open. She retched a little now and then, but nothing was vomited. She tightly clenched her teeth when any attempt was made to separate the jaws. The tongue was clean. Both legs and arms were quite flaccid, and dropped as if dead after being raised. The conjunctival reflex was present on both sides, and the pupils were equal and reacted to light. The pulse was 86 per minute, regular, and of moderate tension; the vessel walls were healthy; the respirations were regular and quiet; and the temperature in the axilla was 99° F. The patient lay apparently unconscious, taking no notice of anything and giving no answers to questions. Both knee-jerks were present, and there was no ankle clonus. On forcibly opening the mouth and pouring a teaspoonful of milk into it the milk was immediately rejected. The heart and lungs showed no abnormality, and the urine contained no abnormal ingredients. The patient's condition remained the same all day. The temperature came down to normal in the evening and the pulse remained good. The unconsciousness continued. I concluded that it was a case of hysteria major. The patient was allowed to remain quietly in bed, but was always watched by one person. She remained in the same state all the second day. On the third day, however, she became less drowsy and answered questions in monosyllables. She took for the first time a little nourishment without opposition. The temperature had remained during all this time between 99·2° and normal. The pulse was always regular and slow. The patient gradually became quite conscious and soon made a perfect recovery. She maintained that she had no remembrance of what had occurred on the two previous days. A month later, when she became "unwell," a similar attack came on in a less severe form. It lasted for a day and a half. No other attack has ever come on since, and she has now been married for a number of years and has had several children.

I think that the clinical features of these two cases which are worthy of note are:—1. The first patient was always delicate, while the second was always strong and healthy. 2. Both patients became rather suddenly ill while they were "unwell." 3. Both were apparently unconscious when I saw them for the first time. 4. Both retched when they first became ill, the retching in Case 1 persisting and that in Case 2 soon stopping. 5 In both cases the teeth were tightly clenched whenever an attempt was made to separate the jaws. 6. In both the conjunctival reflex was present on both sides when first seen.

It was really only the difference in the course of the disease in the two cases when watched for a few hours that made it possible to form a correct diagnosis in each case.

I have purposely given no opinion as to the predisposing or exciting causes of the attack in each case, as I wished merely to give the clinical symptoms and physical signs.

Broadstairs.

Medical Societies.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

Social Legislation and the Medical Profession.—Erysipelas following an Intranasal Operation.—Exhibition of Cases.

THE first meeting of the session of this society was held on Sept. 7th at the Queen's-road Dispensary, Brighton, Mr. T. H. IONIDES, the President, being in the chair.

Dr. W. BROADBENT showed a girl aged 8 with Friedreich's Ataxy. She had been perfectly normal up to four years of age, and was then noticed to be constantly tripping and falling. The child could not now walk at all and had ataxic choreiform movements of the upper limbs. There were curvature of the spine and talipes equino-varus. The knee-jerks were absent and the plantar reflexes extensor. There was an external squint in the left eye, said to have come on since the illness started; the discs were normal and there was no nystagmus.

Dr. DONALD G. HALL showed a baby aged 5, a Cretin, who was improving on small doses of thyroid extract.

Mr. G. MORGAN showed an Anencephalic Fœtus born at the eighth month.

Mr. J TURTON read a paper entitled "Social Legislation and Legislative Proposals in their Relations to the Profession of Medicine." He traced the history of State or communal control of diseased persons from early times to the present day, and in reference to the latest proposal—the National Insurance Bill—he pointed out that the importance of the question of the health of the individual in its bearing upon the welfare of the State was so great and so obvious that legislative proposals in that connexion were at once removed from the arena of political party conflict, and the principles of such proposals being accepted by all parties their discussion immediately resolved itself into a mere question of detail; and paradoxical as it might sound, it might be asserted that in this fact lurked the great danger that in this branch of legislation the Statute Book might be the receptacle of many a crude and ill-digested enactment; for while the ordinary party questions were discussed and re-discussed in principle and detail, for more or less lengthened periods, in Parliament, by the press, and by the public, proposals like those of the National Insurance Bill which effected a revolution in the relations between the public and the profession, excited in Parliament merely an academic discussion on points of detail and formed the subject of negotiations intended to reconcile conflicting views, while the public generally displayed only a languid interest in a matter of great moment and of the very gravest importance to those engaged in the practice of medicine.—The paper was discussed by several members.

Dr. L. A. PARRY read notes of a case of Erysipelas following an Intranasal Operation, complicated with Meningitis, which ended in recovery. The patient was a healthy young man, who, for rather slight symptoms of nasal obstruction, was operated on by a London laryngologist in a nursing home. Two days later he was allowed to travel to Brighton, and in a few days developed an attack of pharyngeal erysipelas, which subsequently spread to the face. A typical attack of meningitis was the next event, and both Dr. E. Hobhouse and Sir Victor Horsley, who saw the patient, gave a practically hopeless prognosis. Large and frequent doses of polyvalent anti-streptococcic serum were given and the patient made a good recovery. Dr. Parry raised the question of the danger of intranasal operations, and deplored, firstly, the very trifling symptoms to relieve which this class of operation was so readily undertaken by the nasal specialists, and, secondly, the short period of after-treatment which the operators seemed to consider necessary. Patients were allowed to be up and out at a time when they should be in bed and having careful nursing.

Reviews and Notices of Books.

The Medical Diseases of Children. By REGINALD H. MILLER, M.D.Lond., M.R.C.P.Lond. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. Bristol: John Wright and Sons, Limited. 1911. Pp. 518. Price 12*s.* 6*d.*

THIS new work on the medical diseases of children will occupy a somewhat ill-defined position in the library of pædiatrics. Its limitations will preclude it from ranking among the larger text-books on the same subject, while it is far removed from the category of a cram book or "aid" for examination purposes. In his preface Dr. Miller states that his aim has been to produce a book of teaching value, and judged by this standard the work is an undoubted success. In one other respect we would quote the preface, for the passage will explain the extreme modernity of the author's methods: "Probably the time will come when we can classify all the infective processes mainly according to the infecting organism, and we shall speak of the pneumococcal, staphylococcal, streptococcal, and other infections as diseases, in the same way that we have for long spoken of tuberculosis and more recently have learnt to speak of rheumatism." Both statement and prophesy reveal the author's general attitude.

When we state that out of 518 pages 168 are devoted to infective diseases we indicate the bias of the work and supply the reader with a key which will admit him at once to the author's real presence. The rest of the book is mainly a compilation, quite fairly and ably made, but one which might have been made and personally supported by many hospital physicians; the chapter on infective diseases is a creation. Among infections, that by the pneumococcus stands first in order. It includes separate sections on infection of the lungs, of the pleuræ, of the heart and pericardium, meninges, peritoneum, kidneys, and joints. The account of pneumonia is excellent, especially that part of it which is concerned with the differential diagnosis between this condition and scarlet fever, acute meningitis, otitis media, appendicitis, cyclical vomiting, and acute tuberculosis. As regards treatment, the value of the ice-bag is emphasised. In the general diagnosis of pneumococcal infection the expedient of the blood count, and in the recognition of pneumococcal meningitis the value of lumbar puncture, are repeatedly referred to. The vaccine treatment of this infection is not mentioned, an omission at which we are not wholly surprised.

Next in order is described the rheumatic infection, an infection which covers a great number of more or less independent lesions. Dr. Miller is careful to explain the liability in children to the generalisation of infections, and this is particularly the case in rheumatism, whether acute or chronic. Since Dr. W. B. Cheadle's original lectures on the rheumatic state in childhood, we do not know a better account of the many and varying manifestations of rheumatism than is here written by Dr. Miller. Moreover, we believe that the author has performed a very great service in indicating the right use of the salicylates. There can be little doubt that the salicylates have a specific influence on the disease, but the dosage may have to be pushed to 150 or 200 grains per diem. The depressing influence of this line of treatment either has no existence in fact or has been greatly exaggerated. The salicylates may, however, produce an acidosis unless combined with a free exhibition of alkalies, and this fact Dr. Miller takes care to emphasise. Thirteen pages are devoted to the subject of chorea, a matter on which Dr. Miller has already communicated his views to the medical world. That he regards chor a

exclusively as a rheumatic manifestation may be assumed without question. Moreover, he believes that in rheumatic subjects, and especially in those of neuropathic tendencies, there is often a condition of latent chorea which is not suspected. Although erythema nodosum and rheumatoid arthritis are included among the rheumatic infections, the author regards them as manifestations of specific diseases, due to bacterial infection distinct from the ordinary infective organism of rheumatism.

Dr. Miller's work accurately reflects contemporary hospital teaching, but there is too much of the labeling of diseases by distinctive and often bacteriological nomenclature; there is too little in his writing of the individual and personal index of the child, both in health and disease; there is too much "cure" and too little prevention. The composite picture of disease is altogether too dependent on sharply defined mosaic work for our liking. The author has presented us with a book which possesses many merits, not the least being the promise of future and better work based on an extended experience.

Der Gynäkologischer Operationskursus an der Leiche. (A Course of Operative Gynæcology.) By Dr. WILHELM LIEPMANN. With 387 (in large part coloured) illustrations. Berlin: August Hirschwald. 1911. Pp. 456. Price 22 marks.

Dr. Liepmann has written an admirable manual of operative gynæcology, presenting several novel and striking features. On four points he lays stress — viz., the anatomy, the pathology, the bacteriology, and the causes of failure in the operations he describes. The anatomy is essentially applied anatomy, and his figures are the more instructive since the subject is in nearly all of them represented in the Trendelenburg position, so that the relation of the structures is the same as that in which they would appear to the operator during the performance of the operation. There are a large number, many of them coloured, of anatomical plates which are of the greatest value, and associated with the description of each operation is a short account of its chief anatomical relations. The pathology of the various procedures is illustrated both by preparations depicting the conditions found at the time of operation and also those persisting after the operation has been completed—conditions of which but little is said in the ordinary text-book of operative gynæcology.

The importance of bacteriological observations at the time of an operation is becoming more and more recognised, and the numerous examples quoted by the author in which such an investigation of the tissues at the seat of operation has led to the adoption of some particular mode of procedure are most interesting. The two operations in which an exact knowledge of the condition of the tissues as regards the presence or absence of organisms is of the greatest importance, are those of extra-peritoneal Cæsarean section and Wertheim's extended operation for carcinoma of the cervix. As Dr. Liepmann has shown, the cellular tissue in the broad ligaments in cases of cancer of the cervix contains not infrequently numerous organisms, and in these circumstances drainage through the vagina is of the utmost importance. No doubt in the future the assistance of the skilled bacteriologist will become a necessity in every well-equipped operating theatre, and upon his findings will depend in many instances the determination as to what particular operation shall be undertaken or whether drainage is necessary in any particular case. In such conditions the results obtained should be even better than they are now, and in many instances a correct conclusion will be come to where at the present time the surgeon would often have very grave doubts as to the best course to pursue.

Another most interesting feature of this work is the space devoted to the causes of failure in any given operation. From these sections the young surgeon will learn much, and a perusal of them will go far towards preventing his becoming involved in difficulties in the course of his operative work. The descriptions of the operations themselves and of the technique are very good, and the whole forms a very complete guide to the subject.

Dr. Liepmann is to be congratulated upon the production of a book of much originality, and one which cannot fail to obtain a wide circle of readers both in Germany and in other countries.

Etiology of Beri-beri. By HENRY FRASER, M.D. Aberd., Director, Institute for Medical Research, and A. T. STANTON, M.D. Tor., Bacteriologist, Institute for Medical Research, Federated Malay States. Singapore: Kelly and Walsh, Limited. 1911. Pp. 89. Price 7*s.*

THIS work contains the results of an inquiry begun under instructions from the Government of the Federated Malay States. Probably there is no disease that has been the subject of more varied hypotheses concerning its intimate nature; but the authors of this valuable treatise have, as can be seen by a study of the book, contributed, it would appear, the key to its elucidation.

The Malay peninsula has long been known as an endemic focus of the malady, and the recorded sickness and mortality during the past several decades show what great economic losses have resulted from its ravages. The researches carried out in 1907 and 1908 that form the basis of the present book were originally published by the authors in THE LANCET of Feb. 13th, 1909, and were editorially commented on in our following issue, and in those of May 8th, August 7th, and Oct. 9th of the same year. The authors found that as the result of observations on 300 labourers, who were divided into two parties of equal number, and were housed some miles apart, those who were given white rice were seized with beri-beri, whilst those who lived on parboiled rice were free from it. They also found that place *per se* or considered as a nidus of infection had no influence on its development. Again, substitution of parboiled rice for white rice among parties of men attacked with beri-beri was followed by the cessation of the outbreak. The existing status of the subject was reviewed in a leading article in THE LANCET of March 12th, 1910.

Next follows a detailed account of their feeding experiments upon fowls with rice, the outline of which also was published by the authors in THE LANCET of Dec. 17th, 1910, in a further communication on the Etiology of Beri-beri. These experiments showed that fowls fed on white polished rice developed a form of polyneuritis analogous to beri-beri in its clinical manifestation and pathological effects, whilst those which were fed on unpolished rice remained healthy. A period of three to four weeks' feeding on white rice was found constantly to cause the development of the polyneuritis. It also appeared that the harmfulness of a rice diet varied directly as the extent to which the rice had been milled; so the authors tested their rice hypothesis still further by adding to a white polished rice, which when given alone was shown to be harmful, a quantity of polishings equal in amount to that which had been milled away, with the result that the fowls remained healthy. They also showed that no poison is developed in the white rice, as it is equally harmful whether freshly prepared or whether stored for months. The subject of the phosphorus content of rice as an indicator of the extent to which rice has been polished is next considered. It was found that Siam polished rice yielded 0·26 per cent., Rangoon polished rice 0·328 per cent., and Malay 0·38 per cent. of phosphorus pentoxide, the incidence of beri-beri

being less the greater the proportion of the latter. Parboiled rice, however, yielded 0·415 per cent. and unpolished rice 0·54 per cent. of phosphorus pentoxide, without any appearance of the disease. As the result of these long-continued and thorough researches, the authors conclude that rice is rendered harmful by the milling and polishing process to which it is subjected in the preparation of white polished rice, as the process removes some substance of high physiological importance in the metabolism. Accordingly, as measures for the prevention of the disease, they recommend the use of unpolished or under-milled rice by the classes of the community in which the disease occurs.

The authors have contributed a most valuable addition to our knowledge of beri-beri; they have made it certain that whilst polished rice will cause beri-beri, unpolished rice will not have this effect. The work contained in this volume will be a monument to their labours in a tropical country.

A Systematic Handbook of Volumetric Analysis. By FRANCIS SUTTON, F.I.C., F.C.S. Tenth edition, revised throughout, with numerous additions by W. LINCOLNE SUTTON, F.I.C., and ALFRED E. JOHNSON, B.Sc. Lond., F.I.C., A.R.C.Sc.I. London: J. and A. Churchill. 1911. Pp. 621. Price 21*s.* net.

"SUTTON," as it is familiarly called by the analytical chemist, is a remarkable book. It stands quite alone in English scientific literature as the one authoritative work on volumetric analysis which is consulted by everyone—the physician, the medical officer, the analytical chemist, the public analyst, the works chemist, the pharmacist, and so forth. It was first produced by Mr. Francis Sutton of Norwich (who is now in his eighty-first year) in 1863, new editions succeeding in 1871, 1876, 1882, 1886, 1890, 1896, 1900, and 1904. The present edition (the tenth) has been prepared jointly by Mr. W. Lincolne Sutton, the author's son, and Mr. Alfred E. Johnson, both of whom can claim an intimate acquaintance with analytical methods and procedure. It is no easy task to bring a work of this sort into line with modern developments, as there are workers in the field in all parts of the world, and it is an onerous undertaking to collect the valuable additions which are made from day to day to the elaborate literature of analytical procedure. Nevertheless, the task has been very well done, and "Sutton" once again is an indispensable source of reference on volumetric analysis, and a work of commercial as well as of scientific importance. It contains sections, for example, on the assay of aniline, soaps, tannin, phosphates, metals, coal-gas, and numerous other products of technical importance, besides chapters on the more recent methods of analysis of urine, water, air, and so forth. References are found in the text to literature of as recent date as 1910, an instance of which occurs in the paragraph on the direct titration of iron by titanous chloride, a new reduction method available for volumetric analyses due to Messrs. Knecht and Hibbert. It may be noted also that portions of the section on sugars have been rewritten, and a well-known authority on the subject (Mr. A. Ling) has contributed an account of his most recent methods of procedure in the use of Fehling's solution. The article on acetone has also been rewritten and recent methods for the analysis of fats have been added. Liebig's method for the determination of urea has become now a mere historic method, which has had to give place to simpler and more accurate technique. In view of the large amount of analytical work that of recent years has been devoted to questions of sewage disposal and water-supply, the sections under these heads have been revised and re-arranged. We notice, however, that the old table giving typical analyses of water and sewage is retained. This might with advantage have been brought up to date, the analyses having been made during a period ranging from 1869 to 1889. Most of the analyses recorded bear the date of 1872 or 1873. This is the only example we have found of an omission to supply figures derived from recent analyses, but it is an important one.

The book is one which a very wide range of scientific workers must keep by them.

Bismuth Paste in Chronic Suppurations, its Diagnostic Importance and Therapeutic Value. By EMIL G. BECK, M.D., Surgeon to the North Chicago Hospital. With an introduction by CARL BECK, M.D., and a chapter on the Application of Bismuth Paste in the Treatment of Chronic Suppuration of the Nasal Accessory Sinuses and the Ear by JOSEPH C. BECK, M.D. With 81 engravings, 9 diagrammatic illustrations, and a coloured plate. London: George Keener and Company. 1910. Pp. 237. Price 10*s.* 6*d.* net.

THE value of bismuth paste in the treatment of chronic suppurating sinuses was discovered accidentally. It was desired to have a skiagram of a sinus, and for this purpose it was filled with a liquefied paste composed of bismuth subnitrate and vaseline. The skiagram obtained showed clearly the ramifications of the sinus, but to the surprise of Dr. Carl Beck and his brother, the sinus ceased to suppurate and has not suppurated since. From this case arose the practice of employing bismuth paste, and the results in certain cases have been very surprising, but necessarily the treatment often fails. Still, its successes have been so numerous that it deserves to be more widely employed. For diagnostic purposes, also, bismuth paste is of great value, for the course and extent of sinuses may by its use and by X rays be recognised to an extent impossible by any other means. Dr. Emil Beck has done well to publish this book so that the method may be more widely known. The method has also been employed in chronic suppuration of the sinuses communicating with the nose, and also after a mastoid operation. It has also been used with some success for pyorrhœa alveolaris. It is possible that its advocates are a little too enthusiastic, but that it is of value can hardly be doubted.

A Manual of Physical Diagnosis. By BREFNEY ROLPH O'REILLY, M.D., C.M., F.T.M.C. Toronto, M.R.C.S. Eng., L.R.C.P. Lond., Demonstrator in Clinical Medicine and in Pathology, University of Toronto; Assistant Physician to St. Michael's Hospital, Toronto; Physician to Toronto Hospital for Incurables. With 6 plates and 49 other illustrations. London: J. and A. Churchill. 1911. Pp. 369. Price 8*s.* 6*d.* net.

THE subject of physical diagnosis, or the correct observation and interpretation of physical signs, is one of vital importance to the student in the study of practical medicine, since the acquisition of correct methods of examination of medical cases is an essential to scientific diagnosis. Dr. O'Reilly supplies in the book before us a useful epitome of the various methods of physical examination, with simple and careful descriptions of the individual signs and of their significance. After some general directions in regard to the interrogation of the patient, so as to obtain a satisfactory clinical history, the rôle of inspection is discussed at considerable length. Various characteristic gaits and facies are described, and then the information afforded by inspection in regard to special systems and organs is categorically dealt with. Some useful details of the topographical relations of the various important viscera are given in a special chapter. The systematic examination of the respiratory, circulatory, digestive, genito-urinary, and neuro-muscular organs is then discussed, all the ordinary methods being clearly

described without unnecessary technicalities. Where instrumental methods afford useful information they are referred to, together with descriptions of tracings and their interpretation. An appendix is devoted to the simpler laboratory methods used in the investigation of urine, blood, sputum, gastric contents, fæces, and serous fluids. A few coloured plates are given, showing the characters of urinary deposits, blood corpuscles, and bacteria.

This book is carefully written and well produced; it should form a useful manual for the student during his work in the wards and out-patient departments, since it is of convenient size, easy of reference, and while avoiding unnecessary detail gives sufficient information to be of real value.

Handbuch der Vergleichenden Physiologie. (*Handbook of Comparative Physiology.*) Herausgegeben von HANS WINTERSTEIN. Vierzehnte Lieferung. Band IV., Physiologie der Reizaufnahme, Reizleitung, und Reizbeantwortung. Erste Hälfte. Jena: Gustav Fischer. 1911. Pp. 161–320. Price M.5.

Dr. Baglioni in this "Heft" continues his exposition of the physiology of the nervous system of echinoderms, and we are particularly glad to see that he does full justice to the excellent work of the late Professor Preyer on this subject, although, of course, like Dr. Baglioni, we can hardly endorse all the views of the former versatile and talented professor of physiology in Jena. His work led up to that of Romanes and others some years ago, and is continued, though from a different aspect, by that of von Uexküll, as well as by American observers. There is apparently no reference to the recent work of Jennings on Starfish, as published in the Carnegie publications. "Autotomy" is dealt with as it occurs amongst both Starfish and Crustacea, and a wonderfully interesting subject it is. This chapter can be heartily commended to the attention of marine biologists.

Over 60 pages are given to the Mollusca, but only a very short account to the Lamellibranchs; the Gastropods fare better, first the marine forms and then the pulmonate or land forms; the latter especially have been extensively studied, but still much remains to be done. To the real aristocracy amongst the Molluscs—the Cephalopods—as befits their eminent position and their remarkable physiological activities—much attention has been given, and the results are chronicled in 60 pages of interesting matter. The physiology of the chromatophores alone is a chapter of the greatest interest, both to the physiologist and to the naturalist. There is far more in the remarkable colour changes than meets the eye. A good comprehensive summary of colour changes in marine invertebrates has yet to be written. Few things are more surprising than the rapidity with which certain of these "quick changes" in colour are effected under nervous influences proceeding from the central nervous system.

The Arthropoda have also been pretty fully investigated. The "reflexes" in the crustacea have been the subject of many investigations. Not the least interesting is the phenomenon of "hypnosis," as manifested by a cray-fish standing on its head; this was described by Czermak many years ago. A full account is given, after Doglein, of the attitudes and reflex activities of the decapod Leander and the conditions which influence and modify its reflex activities. The devices adopted to ensure what is called protective resemblance constitute a wonderfully interesting chapter in the life-history of certain crustacea. Nor are the results of the researches of Pouchet, Keeble, and Gamble on cutaneous colour changes less interesting. Fredericq's researches on self-amputation of limbs—autotomy—are fully set forth, and so are Bethe's results of his elaborate researches on Carcinus mænas, to which several pages are devoted.

Carlson's investigations on the rate of propagation of a nervous impulse in Myriapods are described, and then the author proceeds to deal with the Insecta, obviously a large chapter, of which only the beginning is included in this "Heft." The production of light by certain nocturnal insects, although referred to in an earlier Heft, is again dealt with from the point of view of its relation to the nervous system.

This compilation of Dr. Baglioni on the nervous system promises to be one of great value both to the physiologist and the zoologist.

Kompendium der Topischen Gehirn- und Rückenmarksdiagnostik. By Dr. ROBERT BING, Privat-docent for Neurology in the University of Basle. Second edition, enlarged and improved. Berlin and Vienna: Urban and Schwarzenberg. 1911. Pp. 208. Price, paper, 6 marks; bound, 7.50 marks.

Compendium of Regional Diagnosis in Affections of the Brain and Spinal Cord: A Concise Introduction to the Principles of Clinical Localisation in Diseases of the Central Nervous System. By ROBERT BING, Privat-docent for Neurology in the University of Basle. Translated by F. S. ARNOLD, B.A., M.B., B Ch. Oxon. With 70 illustrations. London: Rebman, Limited. 1911. Pp. 215. Price 10*s.* 6*d.* net.

NOT long ago we reviewed the first edition of this compendium of anatomical and clinical diagnosis, and welcomed it as likely to prove most useful to students and others who desire to familiarise themselves in detail with the clinical anatomy of the nervous system. A second edition has speedily been called for, and the author has taken the opportunity of augmenting that section of the book which deals with cerebral anatomy—a division that, as we remarked at the time, deserved handling on a rather more adequate scale. We are pleased to find that such matters as localisation in the motor cortex, tumours of the ponto-cerebellar angle, aphasia, apraxia, and the pituitary and the pineal glands, are treated in greater detail, and we can cordially recommend Dr. Bing's compendium to student and practitioner alike, both for its excellent diagrams and its readable and accurate text.

The translation of Dr. Bing's Compendium into English also deserves commendation. It is essentially a short practical *vade mecum* of a didactic character, intended to aid the physician or surgeon called upon to localise a pathological process affecting the central nervous system. As we remarked in reviewing the first German edition, one of its most satisfactory features is that the details of clinical anatomy are given with greater completeness than in most text-books, but the addition of unusually clear and simple diagrams prevents these details becoming unwieldy and confusing. With a good index, well printed, and well illustrated Dr. Bing's Compendium in its German or its English form ought to be one of the books to work from in every medical practitioner's library.

LIBRARY TABLE.

Tuberculosis as a Disease of the Masses and How to Combat it. By S. ADOLPHUS KNOPF, M.D. Seventh American edition. New York: Published by "The Survey." 1911. Pp. 124. Price 25 cents.—In this small work Dr. Knopf gives his views as to the measures which should be adopted in an endeavour to combat tuberculosis, mainly dealing with the pulmonary variety. He writes in a popular manner, and gives useful directions as to the mode of life which individuals suffering from the disease should follow. He also indicates the early symptoms of tuberculosis of the lungs. With most of Dr. Knopf's remarks we are in agreement, but we cannot altogether support him in the free use which he makes of the word "cure." For instance, he says: "Of all chronic diseases tuberculosis is the most curable, and of late years

the most frequently cured." In formulating this statement he makes no distinction between the pulmonary form and the other varieties of tuberculosis. With regard to the former, the term "arrest" would often be more suitable, with the addition that in a certain number of cases the arrest proves permanent. We cordially support him, however, in the views which he expresses as to the prophylactic means which should be adopted to stay the spread of the disease. Briefly stated these are: educate the masses in right living and the prevention of tuberculosis; treat the "curable" cases in sanatoriums or at home; take care of the advanced cases in special hospitals; provide "preventoria" for predisposed adults and open-air schools for children; improve the housing of the masses, particularly the sleeping and working quarters; suppress child labour and restrict woman labour; combat alcoholism and other social diseases by sane and humane laws and wise preventive and curative measures. We agree that it cannot be too deeply impressed upon the lay mind that tuberculosis as a disease of the masses has a large social aspect, and that without improving the social conditions of the people tuberculosis will never be eradicated.

Mental Mechanisms. (*Nervous and Mental Disease Monograph Series*, No. 8.) By WILLIAM A. WHITE, M.D. New York: The Journal of Nervous and Mental Disease Publishing Company. 1911. Pp. 151. Price $2.—This book consists of a series of papers dealing with certain psychological and psychiatrical subjects, and is intended to explain and emphasise those fundamentals which appear to the author essential to an understanding of present-day psychiatry. The papers, for the most part previously published independently, tend somewhat to overlap, while their style is diffuse, but as a presentation of a selection of our knowledge on such subjects as consciousness in various aspects and psycho-analysis they are not inadequate.

Physiology of the Central Nervous System and the Special Senses. By N. J. VAZIFDAR, L.M. & S. Bombay: James and Sons. 1911. Pp. 107. Price 2 rupees (or 2*s.* 8*d.*), post free.—This little compilation from well-known English text-books was written for students of the author's class preparing for the intermediate M.B. examination of the Bombay University. It is merely a series of elementary notes with plenty of misprints—e.g., filum terminal, lumber, aqueduct of Sylvias, Gower's tract, Turck, locomor ataxy, Monako's bundle, Grandy, mesentry, papillœ, to mention only a few. With thorough revision it might possibly prove useful for the purpose for which it was intended.

Instructions in the Use of the Catheter, especially Written for Male Nurses. By a Surgeon. London: George Pulman and Sons, Limited. 1911. Pp. 32. Price 1*s.*—That only qualified men should pass catheters on living patients is undoubtedly, as the author says, a counsel of perfection. But inasmuch as patients sometimes require a catheter to be passed four or six times in the 24 hours, it is clearly desirable that the male nurse should be trained to carry out this operation under the directions of the medical attendant. To assist the nurse in performing this duty properly these instructions have been written. They are clear and detailed enough to be grasped, and adequate stress is laid on the methods of preserving surgical cleanliness. The advice given by the writer at the end, if followed, will minimise the danger of over-zealousness.

Album of Photographs issued by the South Indian Branch of the British Medical Association. London: John Bale, Sons, and Danielsson, Limited. 1911. Pp. 55. Price 10*s.* 6*d.* net.—This is a praiseworthy endeavour to collect and render available some of the large amount of material of pathological value that lies buried in the South of India. In the Madras Presidency there is one district European medical officer to about 1,500,000 inhabitants, and even the general hospital of the Presidency has not a whole-time pathologist on its staff. To Captain A. C. Ingram, I.M.S., belongs the credit of the inception of this enterprise, for he wrote to all the medical officers of the Presidency for a loan of photographs of surgical and pathological curiosities, and the South Indian Branch of the British Medical Association undertook the expense of publishing them. One point illustrated by the photographs is the enormous size to which natives in India allow tumours to grow before having recourse to a European surgeon. Among the things pictured are fœtal monstrosities, including cyclops, achondroplasia, leontiasis ossea, myositis ossificans, horny growth from the cheek, a pendulous fibro-lipoma of the neck, multiple fibroma molluscum, mycetoma, elephantiasis of the scrotum, legs, and prepuce, and Mikulicz's disease.

Complete Text-book of Physical Exercises, with 240 Illustrations and Music (specially adapted for the Use of Public Elementary Schools). By ISABEL MURRAY. London: Simpkin, Marshall, and Co. 1911. Pp. 191. Price 3*s.* 6*d.* net.—Physical exercise plays an important part in any well-considered plan of education, and has formed the subject of a recent memorandum issued by the Board of Education. With the object of supplementing the exercises recommended by the Board the author of the "Complete Text-book" has drawn up a number of well-thought-out exercises, which should prove useful to teachers in their efforts to make physical exercises interesting to their pupils. The exercises are graduated for senior and junior classes, and include simple dance steps, maypole exercises, figure marching, and free-arm movements on the march. The movements described in the text are illustrated by diagrams and reproductions from photographs; a selection of popular airs suitable for the exercises adds to the practical value of the book. In all forms of physical exercise it is essential that the interest of the pupil should be maintained, and the author would seem to understand the art of making "drill day" both attractive and instructive.

JOURNALS AND MAGAZINES.

Biometrika. Vol. VIII. Parts I. and II. July, 1911. Cambridge: The University Press. Pp. 256.—The first and second parts of the eighth volume of *Biometrika* contain several papers of medical interest. First, a subject of some importance is discussed by Dr. D. Macdonald—namely, The Pigmentation of the Hair and Eyes of Children Suffering from the Acute Fevers: Its Effect on Susceptibility, Recuperative Power, and Race Selection. The material on which the work is based was obtained by noting the colour of the hair and eyes of all children admitted to the Glasgow Corporation Fever Hospitals during certain definite periods who were suffering from scarlet fever, diphtheria, measles, or whooping-cough. The method employed is to compare the percentage of each particular hair and eye colour found among each of these four classes of fever patients with the corresponding percentage found in the general population of children in the area from which they were drawn, as given by Tocher (Pigmentation Survey of School Children in Scotland, *Biometrika*, Vol. VI.). Broad categories of hair and eye colour are employed: thus hair is classed as black, dark, medium, fair, and red, and eyes as dark, medium, light, and blue. To take an example: 59·4 per cent. of the scarlet fever patients were recorded as having medium-coloured hair, whereas among the control population only 45·2 per cent. are thus described; thus it appears that medium-haired children are especially susceptible to scarlet fever. On the other hand, only 15·5 per cent. of the scarlet fever patients were "dark-haired," instead of 27·2 per cent. found

in the control, so that it may be argued that dark-haired children are less likely to take the disease. Fair-haired and red-haired children occur among the fever patients in about the normal proportion. Results of a corresponding nature are seen when eye colour is considered instead of hair colour, and are approximately the same for diphtheria, measles, and whooping-cough. The author concludes that "the medium-haired child is more liable to become infected than the red-haired, and much more so than the dark-haired and jet black-haired child; the fair-haired child occupies an intermediate position as regards infection." "The medium-eyed child is more liable to become infected than the dark-eyed, and much more so than the blue-eyed child. The light-eyed child occupies an intermediate position as regards infection. The light-eyed child appears to be more susceptible to diphtheria and whooping-cough than to scarlet fever and measles." With regard to these conclusions, the editor of *Biometrika* appends a note of warning—namely, that the hair and eye colour of the fever population was estimated by an observer different from that of the general population. Thus the excess in the medium class of both hair and eye colour in the former may be due to the personal equation. This possible source of error is not present in that part of the work which deals with the relation between recuperative power and the pigmentation of hair and eyes, since here no comparison with the general population need be made. With two exceptions that do not invalidate the conclusion, it is found that for these four diseases the percentage of severe cases and the percentage of deaths are smaller among dark-haired children with dark eyes than among medium-haired children with medium eyes, and that they are smaller among the latter than among fair-haired children with light eyes. Red hair occupies an intermediate position with regard to recuperative power between medium and fair. G. D. Maynard contributes a note on the age distribution of deaths from diabetes mellitus. His statistical analysis shows that deaths from this disease fall into three classes corresponding with growth, reproduction, and old age. The age distribution of deaths in each can be described by simple frequency curves. The mean age of death in the first-named class is (for males in England and Wales) 9·5 years, in the second 30·84 years, and in the last 69·37 years. By summing the three simple curves a complex curve is arrived at which represents fairly accurately the general death-rate from diabetes at different ages. Professor Karl Pearson, in a paper entitled "The Opsonic Index—'Mathematical Error and Functional Error,'" controverts two views expressed by Sir Almroth Wright: firstly, that "the enormous working errors in opsonic estimation" are largely functional errors due to a faulty application of the method by imperfectly trained observers, and only to a small extent errors of method; secondly, that functional errors cannot be evaluated by a mathematician. Professor Karl Pearson has set himself as a mathematician to evaluate the "functional error," and in so far as his material goes he finds it as great in Sir Almroth Wright's laboratory as elsewhere; but wherever found he considers it small compared to errors arising from such other sources as "random sampling." Dr. Frank Rock's short note on the Tooth-brush and Decayed Teeth may perhaps be considered of medical interest. It is based on the medical examination of 556 boys and 507 girls, all over 13 years of age, in schools at Edmonton. He finds that there is practically no correlation between the number of decayed teeth in the mouth and the daily or occasional use of the tooth-brush or its total neglect. The tooth-brush may improve the appearance of the teeth, but it does not appear to arrest decay. Possibly the tooth-pick may be of greater value. Of the remaining papers three deal with anthropometry—namely, the late Dr. Crewdson Benington's long and important work on Cranial Type Contours, J. I. Craig's Anthropometry of Modern Egyptians, and E. Schuster's First Results from the Oxford Anthropometric Laboratory. General biology is represented in a Third Coöperative Study of Vespa Vulgaris, by E. Y. Thomson, Julia Bell, M.A., and Karl Pearson, F.R.S.; on the Correlation between Somatic Characters and Fertility, by J. A. Harris, Ph.D.; the Inheritance of Fertility, by R. E. Lloyd, D.Sc.; Karl Pearson's remarks on Professor Lloyd's note, and his Further Remarks on the Law of Ancestral Heredity. There is one purely physiological paper on Pulse and Breathing Rates and their Relation to Stature, by Julia Bell, M.A. Two may be classed possibly under the heading pædagogy, the Teacher's Estimation of the General Intelligence of School Children, by H. Waite, M.A., and on the Significance of Teacher's Appreciation of General Intelligence, by W. H. Gilby, B.Sc., assisted by Karl Pearson, F.R.S. The remainder of the volume is concerned with statistical technique.

Klinik für Psychische und Nervöse Krankheiten. Herausgegeben von ROBERT SOMMER, Professor an der Universität Giessen. Band V., Heft 3, and Band VI., Heft 2. Halle: Carl Marhold. 1911. Price 3 marks each.—Band V., Heft 3, contains several papers of interest. 1. Dr. Steinbrecher's paper on the differential diagnosis of internal hydrocephalus concerns a case in which the symptoms of an infratentorial tumour were present, but the post-mortem examination revealed simply internal hydrocephalus. A number of similar cases are already on record. 2. Dr. Berliner describes a case of dementia paranoides apparently the result of a severe accident, and discusses the relation of the two. 3. Dr. Klett publishes a paper on the graphic representation of certain movements of expression, and describes in detail his method for registering the movements of the occipito-frontalis muscle under varying conditions. In Band VI., Heft 2:—1. Dr. Pfahl continues his communication on the investigation of voluntary movements by graphic methods. 2. Dr. Helmut Müller deals with a long series of personal experiments on the teaching of mentally defective individuals. He comes to the conclusion that in memory experiments with defective patients better results are obtained if the matter to be taught, say a line of poetry, is taught one half at a time (even though the words do not make sense), whereas in normal individuals the opposite holds good—viz., that the line should be learned from the outset in its entirety. 3. Dr. Margulies publishes a long paper on hystero-epilepsy, *apropos* of a case in which the method of psycho-analysis is applied to determine and to separate the hysterical from the epileptic elements in the clinical phenomena.

COLONIAL MEDICAL SERVICES.—*West African Medical Staff:* Mr. J. B. H. Davson, senior medical officer, Sierra Leone, has retired on a pension. Mr. J. P. Fagan, deputy principal medical officer, Northern Nigeria, has been promoted principal medical officer, Northern Nigeria; Dr. F. G. Hopkins, deputy principal medical officer, Southern Nigeria, has been promoted principal medical officer, Gold Coast; Mr. F. Manning, senior medical officer, Northern Nigeria, has been promoted deputy principal medical officer, Northern Nigeria; and Mr. E H. Tweedy, provincial medical officer, Northern Territories of the Gold Coast, has been promoted deputy principal medical officer, Gold Coast. Mr. R. H. Brierley, formerly a medical officer in Southern Nigeria, has been reappointed to the staff. The following gentlemen have been selected for appointment to the staff: Dr. L. W. Davies (Northern Nigeria) and Dr. J. B. Alexander (Gold Coast).—*Other Colonies and Protectorates:* Mr. W. H. Bomford has been selected for appointment as a Medical Officer in Fiji. Mr. W. Parsons has been selected for appointment as Medical Officer in charge of the Quarantine Station at Singapore, and Mr. E. Sutcliffe has been selected for appointment as a Supernumerary Medical Officer in the Leeward Islands.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 16, 1911.

Condensed Milks in the Infant Dietary.

THE investigations on public food questions which are undertaken by the Local Government Board from time to time reflect the highest credit upon that department. Already a valuable series of reports has been issued dealing with subjects of considerable public urgency. There have thus been published 14 reports, and a fifteenth report has just reached us in which the very important question of condensed milks in regard to their use as infants' foods is discussed. Dr. F. J. H. COUTTS is the author of the latest report, and it is obvious from the careful and painstaking inquiries that he has made that the present state of things in regard to the sale of condensed milk is most unsatisfactory and in many instances seriously opposed to the interests of public health. He has definitely ascertained that machine-skimmed condensed milk is used on a considerable scale for feeding infants, and he gives evidence in favour of the conclusion that this use is increasing. In spite of an honest label declaring the milk to be "machine skimmed" the mother buys the preparation; her poverty tempts her, and her ignorance may lead her to believe that she is taking the best course; and on all sides, therefore, infants are reared on a starvation diet. For to many poor women the words "machine skimmed" have a magic meaning, the milk has been treated by machinery not touched by hand, and is, of course, on that account specially pure. Others imagine the milk in the tin with these words upon it to be the thick rich milk from the top. Far, therefore, from deterring the use of such milk for infants, the words of the honest label actually appeal to the mother. It is well to remember in this connexion, too, that machine-skimmed milk is more profitable for the retailer to sell than the variety known as full-cream milk The temptation to sell an article yielding 15 to 20 per cent. profit instead of 10 per cent. is hard to resist, but the acute sufferer over the advantageous deal is the helpless baby.

Dr. COUTTS'S most valuable recommendation, in our view, is that which refers to the prevention of the use of condensed skim milk for infant feeding. This is what is demanded in the name of humanity. The words "skimmed milk" or "machine-skimmed milk," which some firms put on the labels of their machine-skimmed milk, should not be in small type on an obscure part of the label or associated with words advising the use of certain full-cream blends produced by the same maker. "All these things," rightly observes Dr. COUTTS, "tend to confuse the purchaser and to lead to failure to recognise the real meaning of the warning." We agree with his view that some parents fail to understand how unsuitable these milks deprived of fat are for feeding babies, but a clear declaration could not fail to have some effect in educating them to know that all condensed milks are not alike in composition. Such a declaration would materially assist the efforts of all who are working to decrease our miserable infant mortality—medical men, nurses, and health-visitors alike—by impressing upon mothers the danger of such foods. If a definite declaration on the tin itself of the unsuitability of the food for infants could be pointed to a great difficulty would be surmounted. We suggest, however, that the words "unfit for infants" which Dr. COUTTS recommends for the labels of machine skimmed milks would create an unwarranted prejudice against the sale of the food for other and perfectly legitimate purposes. Machine-skimmed milk provides an abundance of valuable proteins, carbohydrates, and phosphates, and is of use, therefore, in the making of tea, coffee, cocoa, milk puddings, and custards. The words "unfit for infants" are calculated to create an impression that if the food is "unfit for infants" there must be something wrong about it for general purposes. We therefore think it would be better and more reasonable to demand that machine-skimmed milk should be labelled more or less as follows: "Not a substitute for mother's milk." Upon the question whether whole condensed milk, assuming that the purchaser has no difficulty in obtaining it, is suitable for the infant's needs, there is considerable divergence of medical opinion. Dr. COUTTS is inclined to think that there has been some tendency to exaggerate the evil effects of feeding on full-cream condensed milk. It is probable that a considerable proportion of children may thrive tolerably well when fed even over prolonged periods with a high quality of condensed milk, if the directions as to its dilution are sound and followed; but the coincidence of epidemic diarrhœa and condensed milk feeding, whether skimmed or whole, is a serious factor in the situation. In the case of skimmed milk every disorder that is the natural sequence of malnutrition may be anticipated, and the prolonged use of full-cream condensed milk is a very doubtful recommendation in the face of medical evidence upon the results of such a diet. In the returns made from time to time by medical officers which indicate the serious liability to epidemic diarrhœa in infants fed on condensed milk no differentiation is made between full-cream and machine-skimmed milk, and it may possibly be the case, as Dr. COUTTS points out, that in some places the evils attributed to condensed milk may be partly due to the machine-skimmed variety. Again, the question whether full-cream condensed milk has any advantages over the same preparation condensed and preserved with the addition of sugar must not be left out of the calculation.

Many authorities ascribe the occurrence of rickets to overfeeding brought about by an excess of carbohydrate which unduly taxes the infantile metabolism — to, in fact, a want of balance, apart from a possible deficiency in fat, in the proportions of the various constituents of the food. "I have never seen," says Dr. ERIC PRITCHARD, "an infant uninterruptedly fed for six months on condensed milk—which is, of course, milk which has been

vigorously sterilised—who did not present unmistakeable symptoms of rickets." Dr. NEWSHOLME, the principal medical officer of the Local Government Board, holds that the importance of rickets as a cause of other diseases as well as deformities in childhood and in after life is insufficiently understood, and there is surely sufficient evidence to warrant the prompt establishment of new and more effective machinery that is calculated to exercise control over all articles supplied as food for infants, including condensed milk in its various forms. The State should step in wherever possible to prevent the waste of infant life which is due to ignorance and poverty, and, in the case of condensed milk, to render more difficult the commercial game of making things appear to be what they are not.

Cæsarean Section in Possibly Septic Cases.

THE operation of Cæsarean section, with its modifications, has attracted a good deal of attention of late, and in a manner which is of particular interest to the general practitioner, who in the first instance may have to bear the grave responsibility of the course to be pursued. The introduction within the last few years of the method of so-called extra-peritoneal Cæsarean section has given rise to much discussion, not only as to the merits of this modification of the operation, but also as to the conditions under which it should be performed. One of the most difficult problems which still remains to be solved is, What is the correct treatment to adopt in the case of women with contracted pelves who are in labour, and possibly or probably already infected? In some, at any rate, of these cases delivery through the natural passages may not only be very dangerous for the mother but must inevitably entail the sacrifice of the child's life. The answer to the question demands the consideration of the method of delivery which is best calculated to save both the life of the mother and of her child, and the crucial point is to determine whether any patient in these circumstances is infected or no. When the operation of extra-peritoneal section was first introduced it seemed to hold out the possibility of dealing safely even with definitely septic cases. The results obtained were, however, discouraging, and the general opinion at the present time is that this operation is not suitable for such cases. SELLHEIM has attempted to overcome the difficulty by his ingenious method of forming a permanent utero-abdominal fistula for the purpose of providing free drainage, and so avoiding the danger of infection from the septic interior of the uterus.

The whole question has been discussed on several occasions recently, and it formed one of the subjects for discussion at the Fifth International Congress of Obstetrics and Gynæcology held at St. Petersburg a year ago. On that occasion Dr. AMAND ROUTH presented a report of all the Cæsarean sections performed in this country by over 100 obstetricians and gynæcologists who were living on June 1st, 1910. This report has now been published.[1] The total number of the cases collated amounted to 1282, and the document is a model of what such a report should be and will long remain a mine of information on the subject of which it treats. At a meeting of the Obstetrical Section of the Royal Society of Medicine of London held in March of this year the question of Cæsarean section and its alternatives in women with contracted pelves who had been long in labour and exposed to septic infection was considered, the discussion being opened by Dr. ROUTH. A large number of obstetricians and gynæcologists from all parts of the kingdom took part in the discussion, and all the points involved were very fully considered. Dr. ROUTH'S figures show very clearly the enormous difference which exists in the death-rate from Cæsarean section in clean, non-infected cases, as compared with that in suspect or infected cases; the death-rate in the latter amounts to some 17·3 per cent., or to 34·3 per cent. in almost certainly infected cases, as compared with a death-rate of only 2·9 per cent. in the non-infected or clean cases. As Dr. ROUTH truly remarked, the ideal operation for infected cases would be one which is free from the fœtal mortality of craniotomy, from the maternal mortality of the classical Cæsarean section, from the morbidity of pelviotomy and extra-peritoneal Cæsarean section, and from the sterilisation which accompanies all forms of hysterectomy. The difficulty in coming to a conclusion upon the results obtained by various operators lies in the fact that it is almost impossible to say whether any given patient is infected or not. Further than this, in many cases the infection is purely a local one, and remains so; and in other cases the condition is one of commencing general sepsis, and the patient will probably die, whatever be the manner in which she is delivered.

It was suggested by Dr. ROUTH, in opening the discussion, that the assistance of the bacteriologist should be invoked, so that by means of swabs taken from the cervix and the interior of the uterus the presence or absence of septic organisms could be ascertained. It was pointed out at once, however, that there may be great difficulty in determining, at any rate with sufficient rapidity, whether a given organism is a virulent one or not, and, as is well known, many forms of apparently pathogenic organisms may be present in the genital tract of a parturient woman and yet she may present no signs of sepsis and pass through a perfectly normal puerperium. It must be concluded, at any rate at the present time, that the plan of taking a swab from the cervix or from the liquor amnii in such cases is not likely to prove of much clinical value. In the first place, the pathologist is not likely to be at hand just when he is wanted; and, in the second place, his verdict must often in our present state of knowledge be far from accurate and therefore not to be relied upon with certainty. It is very necessary to make a careful distinction between infection of the liquor amnii—a purely local condition and dangerous to the patient only if the peritoneal cavity become infected, and infection of the tissues of the uterus itself—a much more

[1] Cæsarean Section in Great Britain and Ireland. With Tables of 1282 cases of Cæsarean Section by over 100 Living Obstetricians and Gynæcologists in Great Britain and Ireland. Being a Report read at the Fifth International Congress of Obstetrics and Gynæcology held at St. Petersburg in September, 1910. By Amand Routh, M.D. Lond., F.R.C.P. Lond., Obstetric Physician to Charing Cross Hospital, London, and Consulting Physician to Samaritan Free Hospital for Women, London. London: Sherratt and Hughes. 1911. Pp. 233. Price 5s.

dangerous state of affairs, and one requiring more radical treatment if it is to be dealt with effectively. Here again, however, we are met with the same difficulty, When is the liquor amnii infected and how are we to determine this with certainty? Any conclusion upon this point must be mainly guesswork, and no reliance can be placed upon the presence or absence of an offensive odour. Some are in favour of a procedure carried out by Dr. DRUMMOND MAXWELL in one case, in which he irrigated the amniotic cavity and then performed Cæsarean section, but this method can have, we fear, but a very limited scope, and in the presence of really virulent organisms would prove of little value. In cases where the liquor amnii appears to be certainly infected, most reliance must be placed upon careful isolation of the peritoneal cavity, on eventration of the uterus, and on the application of the ordinary surgical principles which would be employed in dealing with any other septic abdominal condition requiring laparotomy. An interesting feature of the discussion at the Obstetrical Section of the Royal Society of Medicine was the very small amount of support accorded to the operations of pubiotomy and extra-peritoneal Cæsarean section. It is true that few of the speakers seemed to have much experience of either operation, and the arguments brought against them were not founded upon actual occurrences. Regarded from the critical standpoint it would appear, however, that neither of these two operations is suitable for really septic cases, and indeed that appears to be the view of most authorities at the present time. That they may both be attended with very good results in clean cases is certain, but their exact place among obstetrical operations still remains to be defined with precision in the future.

No one would be found to recommend craniotomy on the living child, but cases will inevitably occur from time to time when the safest procedure from the mother's point of view will entail the sacrifice of her child, and in this country the opinion in such cases has always been, and still is, that the life of the mother must be considered of greater value than that of the child. In certain cases and circumstances there is no procedure available which minimises the risk to the mother to so great a degree as craniotomy, and while these conditions remain so long will the operation be justifiable in selected cases. For doubtfully septic cases, when Cæsarean section is thought advisable, it should certainly be followed by removal of the uterus, which in all probability is infected. If the infection is still a local one the mother's life will generally be saved, while if it has already become generalised she may die, no matter what procedure is adopted. It is possible in the future, when we have more knowledge of the different varieties of pathogenic organisms and are able to recognise with certainty those which are virulent, that the bacteriologist may prove of help, but for the present the question of the presence of sepsis must remain largely a matter of dubiety, and the doubtful cases can only be treated safely if they are considered as septic even when they are only suspect. In such cases the peritoneum must be jealously guarded from infection, and the whole uterus had better be removed, if the operation can be undertaken in suitable surroundings. In unsuitable surroundings craniotomy must still be resorted to. We may hope in time to relegate the operation of craniotomy on the living child to its place among the obsolete barbarities of the past, to which it has been compared by some authorities, and all will rejoice when that day comes. In the meantime, however, facts must be dealt with, and in cases where the risk to the mother is minimised by the operation of craniotomy we must not hesitate to resort to this procedure. Such cases will certainly occur from time to time in general practice.

The Progress of Anæsthetics.

WE do not remember a meeting of the British Association in which so many problems of the highest scientific import were introduced under what may be called their popular aspects, and the manner in which this was done is a clear proof that the national education in science, so profoundly hoped for by medical men, is really now proceeding. Many of the papers in the different sections invite medical discussion, as might have been expected, now that the boundaries of scientific medicine are so indefinitely enlarged, but none, perhaps, concerns our readers, the practising medical profession, more closely than the third interim report of the committee appointed some time back by the British Association to investigate the problems of anæsthesia. The committee consists of Dr. A. D. WALLER (chairman), Sir FREDERIC HEWITT (secretary), Dr. J. BLUMFELD, Mr. J. A. GARDNER, and Dr. G. A. BUCKMASTER, and its report deals with the commonly accepted principles which control the administration of ether as a general anæsthetic by inhalation. This subject fell within the purview of one of the preceding reports and has occupied the members of the committee during the past year. An attempt was made, which proved successful, to obtain evidence as to whether a 10 per cent. vapour of ether, when given by inhalation, would be competent to ensure anæsthesia. It will be remembered that this strength of vapour in air given to the lower animals in the laboratory by a continuous method gave satisfactory results. In an appendix to the report the matter is carried further. Ether presented by an open method—i.e., dropped continuously upon an absorbent material and approximated to the face—was studied. The maximum strength of the vapour so produced in the ordinary course of the induction and maintenance of surgical anæsthesia was found in one observation to be 20 per cent. This maximum fell during the continuance of the administration as the result, we are told, of evaporation and cooling. In a second observation the percentage was found to be 14·6 after an interval of two minutes, and 11·6 after 24 minutes. A third observation gave a percentage of 9·2 after 16 minutes; while in a fourth case subsequently to a 12 minutes' inhalation the percentage strength of the ether was estimated to be 9·7. In this case an attempt was made to increase the percentage to above 12, but this was found to be impossible by the means adopted—viz., adding excess of ether. The points which this interesting research appears

to enforce are that the method of giving ether by an "open" system, while it induces adequate anæsthesia for human beings, yet automatically keeps the strength of the vapour within the limit adopted by the committee as being safe—10 per cent. The history of ether administration reveals curious oscillations of fashion. In its initial trials as an anæsthetic, besides the attempts made to supply a vapour by means of the crudest of inhalers, a quasi open plan was adopted, but proved unsatisfactory, owing to the fact that no attempt was made to attenuate the strength of the vapour supplied, with the result that distressing sensations of strangulation arose and dangers occurred incident to the wild struggles of the unfortunate patient. On the continent, where a modified open method is much in vogue, such as that adopted by Dr. DUMONT of Berne, enormous quantities of the anæsthetic are used, and the patients appear in many instances to be liable to post-anæsthetic dangers such as pulmonary or renal catarrh.

The plans so popular in England at the present time, which are based upon those introduced from the United States, are less open to adverse criticism. They avoid the deleterious addition of an impervious cover to the mask, and permit free through-breathing, thus ensuring evaporation and the automatic adjustment of the strength of the vapour inhaled. Again, in frequent cases the plan is adopted, the importance of which has been insisted upon by so many of the continental surgeons, of systematic dropping applied to the ether supply instead of the douching in bulk, which is at once wasteful and open to a charge of producing grave consequences. Sir FREDERIC HEWITT, in one of the appendices, deals with the subject of open ether, and his experience of it has led him to eulogise the method; indeed, he appears to regard it as superior to others involving the employment of closed inhalers such as those due to Clover, Ormsby, and the countless modifications of these types. The simplicity of the procedure commends itself to all who have acquired the technique, and those who extol it appear to believe that the incidence of danger to life during its use is not greater than is inherent to the performance of severe surgical operations upon patients in a condition of physical collapse. This point cannot be decided so far, nor must too much importance be attached to the distress which many patients experience as the result of the clinging and persistent odour which prolonged ether inhalation leaves behind it. It is perhaps premature as yet to accept the view enunciated that ether will as a result of the improved methods of its use wholly supersede chloroform in surgical anæsthesia. We may well suppose that many will take a more conservative line, and while advocating a wider adoption of ether in surgery will yet regard chloroform as possessing merits all its own which single out that anæsthetic as ideal in certain circumstances. The report and some of its appendices, indeed, deal with chloroform and reaffirm its comparative safety when employed by scientific and precise methods. The researches of SNOW, and later of PAUL BERT, initiated the dosimetric method of giving chloroform vapour, and established by experiment and clinical observation that there exists a limit of safety—a 2 per cent. vapour of chloroform in air. Their researches have been elaborated recently by Dr. A. D. WALLER, by the Special Chloroform Committee of the British Medical Association, whose report has been lately published, and by others. In the report before us we learn that the balance chloroform inhaler, the invention of Dr. WALLER, which supplies an exact dosage, has been adopted in the practice of St. George's Hospital, and experience with it has further shown the safety of a 2 per cent. vapour, while it has supplied a valuable means of teaching students the principles of dosimetry as applied to anæsthetics.

Mr. A. G. VERNON HARCOURT, the inventor of the well-known dosimetric chloroform inhaler which has been so widely used with good results, read a paper before the British Association during its recent meeting, and pointed out that the inhaler which he has perfected, while being simple and portable, fulfils its primary object—namely, to supply and control a chloroform and air mixture of definite percentage value. We do not deal in this place with the technical details of Mr. VERNON HARCOURT'S discourse, although it repays careful study. Whether or not we admit that the last word has been said upon the *quæstio vexata*, Is ether or is chloroform to be adopted to the exclusion of the other? and, again, whether the dosimetric methods eulogised in the present report are final or tentative, none will gainsay the fact that public opinion is being rapidly aroused to the importance of the questions which have been mooted. Anæsthetics to-day are needed so constantly and so imperatively that it is essential that the public should be safeguarded. It is of no avail to perfect methods unless the public are made aware that safety lies not in their individual ability "to take an anæsthetic well," but in the ability of the administrator to give it well. Nor can such a thing be possible in the case of all and sundry. By dint of careful teaching and opportunities of constant practice medical men acquire this power, and it is to the interest of the public both that the education of our medical students should be perfected in this regard, and that this procedure of surgery should be restricted to those who possess adequate and recognised surgical and medical qualifications, at least when the graver procedures of surgery are in question. Every thoughtful person will agree that all unqualified practice is an evil, especially to the public at large, but this evil becomes greatly accentuated when the unqualified practitioner employs such powerful drugs as fall within the armamentarium of the anæsthetist. Various attempts at legislation upon this subject have been made, and now a draft Bill has been lodged at the Home Office to the terms of which there seems a general consensus of professional and official agreement. We may well hope that not only the administration of anæsthetics, but other departments of the healing art will in the near future receive more protection, since the legislation required is aimed not at safeguarding the pockets of the medical profession but at protecting the public—all of them, and not only the poor and ignorant—from the perils of unqualified practice.

Annotations.

"Ne quid nimis."

THE ANOMALIES OF PLAGUE INCIDENCE IN INDIA.

SOME attention has already been drawn to the anomalies of the present incidence of plague in India. When the disease was imported into that country from China in 1896 it spread rapidly, being conveyed, as our readers are aware, from the port of Bombay by refugees and others into the neighbouring provinces and native states, ultimately extending over vast tracts of the empire. While the infection spread like wildfire in some provinces, in others it only smouldered, as it were, never assuming what might be regarded as epidemic proportions; while yet in other provinces plague, though introduced time after time, never seemed to gain a foothold, nothing more serious than a few sporadic cases being reported. The main brunt of the plague incidence in India has been borne by three provinces—namely, the Punjab, Bombay, and the United Provinces of Agra and Oudh, which together have a combined population of about 97 millions—that is, roughly speaking, about a third of the whole population of India (calculated on the Census of 1901). In the three provinces during the last 15½ years, from 1896 up to the middle of 1911, no fewer than 5,435,266 deaths from plague have been registered. This number, however, is probably below the actual reality as, for various reasons, deaths from plague are known to have been ascribed, intentionally or otherwise, by the natives to other causes. As compared with these figures it may be stated that during the same period throughout the whole of India, excluding the three above-named provinces, only 1,942,057 fatal plague cases were certified; so that of the total 7,377,323 deaths from plague recorded in India in the last 15½ years about five-sevenths occurred in the three provinces already mentioned, with about a third of the entire population of the country, the remaining two-sevenths occurring in the rest of India, with some 200 millions of inhabitants. On the other hand, although plague has been persistently present in the Presidency of Madras since 1897, less than 80,000 deaths from this cause have been reported, although the population involved is about 42 millions. If we contrast with this the mortality from plague in the Punjab during the same period, in a population of about half that of the Madras Presidency, we find that there were in it no fewer than 2,436,105 plague deaths. The city of Madras with over half a million inhabitants has had an almost complete freedom from plague since its introduction into India, and though the infection has been imported time after time there has been no spread of the disease in this city. When the case of Eastern Bengal and Assam comes to be considered the contrast is still more marked. This province was constituted in 1905, and has at the present time, according to the Census of 1911, a population of nearly 34 millions. Comparison with other provinces as to plague incidence is limited to a period of six and a half years—that is, from the beginning of 1905 to the middle of 1911. In that period in the new province only 146 plague deaths have been reported, as compared with 1,575,866 in the Punjab with about 10 millions less population; 1,266,186 in the United Provinces with about 13 millions more inhabitants than Eastern Bengal and Assam; and 334,639 plague deaths in the Bombay Presidency, the population of which is more than 10 millions less than that of the new provinces. In the Presidency of Madras, in the six and a half years under consideration, 25,780 plague deaths were recorded, its population being, as has been said, about 42 millions. The causes which have led to this unequal distribution of plague mortality in these provinces of India have so far remained undiscovered. Why, on the one hand, the Punjab should experience such an appalling mortality from plague; why, on the other hand, the Presidency of Madras, with twice the population, should escape with comparatively so small a record of fatal plague; and, above all, why Eastern Bengal and Assam should practically have complete freedom from this epidemic disease, though the infection has been repeatedly imported into it, are problems still unsolved. The investigations of the Indian Plague Advisory Committee, appointed jointly by the India Office, the Royal Society, and the Lister Institute in 1905, have demonstrated already that the spread of bubonic forms of plague, the prevalent type of the disease in India, is brought about through the agency of the rat flea. Rats and fleas, it would seem, are as common in Madras and in Eastern Bengal and Assam as they are in the Punjab or the United Provinces. So far as can be learned the conditions for the spread of plague are much the same in all of these provinces above named. In the circumstances we are glad to hear that the subject has engaged the attention of the Advisory Committee, whose expert representatives have already visited the Presidency of Madras and the Province of Eastern Bengal and Assam to collect information and to inquire, with the help of the respective Sanitary Commissioners and their staffs, into the local conditions which might be thought of as likely to affect the question of the apparent inability of plague infection to spread in one or another place. Perhaps it is justifiable to hope that the information collected in this way by the Advisory Committee may ultimately be found to serve as a basis for devising further measures for arresting the long-continued prevalence of plague in the Punjab and in the other heavily affected provinces, and may in this way lead to the prevention of much human suffering and to the saving of many lives.

ARTIFICIALLY COOLED HOSPITALS.

ONE of the most essential points to be attended to in the construction of a hospital in this climate is the installation of a suitable system of heating. It may be added that the proper working of even the most perfect system that can be devised is very often one of the most difficult matters to settle to the general satisfaction of the inmates. We do not, however, make any methodical endeavour to bring about artificial cooling, though during the present summer there must have been many occasions when such an installation would have been of therapeutic benefit. Dr. Charles E. Woodruff of Manila, in the Philippines, has drawn attention to this subject in *American Medicine* for July last. He refers to the reported case of sleeping sickness treated in a room fitted with a cold storage plant, where the daily stupor was reduced from 23 to less than 19 hours, and states that in a series of cases of dysentery in a tropical hospital improvement took place very slowly, if at all, when the temperature was over 82° F., while when it dropped below 80° there was a marked change for the better; and if it came down below 75° the patients would be soon up and about. The nearer the temperature is to 70° or 68° the better it is for the patient. He points out that the tropical negro is adjusted to a considerable range of temperature, and survives a southern outdoor life in America, but he dies from tuberculosis when taking up indoor house labour in the north. Dr. Woodruff believes that every type of man is fettered by his physique to a very limited environment, and if he is adjusted to cold air then he must have it, or he will in some way deteriorate. Thus,

cold air is good for consumptives of white race belonging to temperate climates. A hot, equable, sunny climate is not so good for such cases as a cold, variable, cloudy one, as is shown by the contrast between the bad results of treatment in the Philippines and the good results obtained in the Adirondack Hills of New York State. All cases cannot, however, be transported to an appropriate climate, so that a proper environment must be provided locally. The cooling of the air of hospitals is a simple matter. All that is needed is a "steam coil" or "radiator," in which circulates cold brine instead of hot water. This does not radiate, it absorbs, heat. According to Dr. Woodruff, all the air needed to ventilate a ward of 12 beds can be cooled from 95° to 55° by an electrically driven apparatus of the capacity known as a "one kilo-watt ammonia compression set," which can be installed on a base 10 feet square. As the coils drip moisture they cannot be put in a ward. Also, the air is damp when it leaves the coils, but it warms up on its way to the ward; or, if needed, can be warmed artificially so as to be delivered dry. The method may be carried out for ordinary dwellings as well as hospitals. Health would be preserved longer, and more work could be done with greater ease, if a northerner living in the tropics could live in and breathe air at a temperature of 55°; and this might be effected if the same expenditure were allowed for cooling in the tropics as for warming in cold temperate regions. It may be some years before in these islands we get a recurrence of the exceptional heat of the present summer, but in nearly every year there are spells of sultry weather which are extremely trying to a considerable proportion of hospital patients. The installation of a cold room for suitable cases would be an admirable offering from some wealthy and benevolent person.

DR. CARL SPENGLER'S "I.K." TREATMENT FOR TUBERCULOSIS.

SINCE Professor Koch first introduced tuberculin for the treatment of tuberculosis several modifications of that substance have been made and experimented with. Dr. Carl Spengler, whose researches on the subject are well known, has more recently made trial of a derivative of Koch's original tuberculin which he has named "I.K." We have received a communication from Dr. H. W. Godfrey containing an interesting *résumé* of Dr. Spengler's investigations and also the results of his own experience with this remedy. Dr. Godfrey explains the various steps which finally enabled Dr. Spengler to form "I.K.," and further states that it is a clear solution rendered durable by the addition of carbolic acid and sodium chloride solution. It has a two-fold action—antitoxic, which neutralises the poisons produced by the bacillus, and is therefore, directly antifebrile; and secondly, a lytic or bactericidal action. Dr. Godfrey has treated several patients with "I.K.," and sums up his conclusions thus: "One of the first effects of the I.K. treatment is an improvement in the subjective condition of the patient, he feels better, the breathing is easier, and as a rule the appetite is improved and weight gained, there is a decrease in the rhonchi audible, and the sputum after a few injections is lessened, though at first it may temporarily increase, and the temperature falls in some instances rapidly." Dr. Godfrey then proceeds to give brief notes of the cases of eight patients whom he had treated by this remedy. His results are rather startling. At the termination of the course of treatment all the patients were either in "perfect health," "perfectly well," or "quite as well as usual," and one had been "medically examined for insurance and accepted." He does not state whether "I.K." had been tried in other of his cases with less wonderfully good progress We are moved, however, to point out that this preparation has been tried by competent observers who have entirely failed to obtain the results claimed by Dr. Splengler and Dr. Godfrey. There is nothing more fallacious than to judge of any treatment for pulmonary tuberculosis which has only been tried in a few cases. A very large number of recorded instances are required before any definite conclusion can be arrived at; and, further, the preparation must be used by numerous physicians and their results carefully compared. The pupils and friends of Dr. Spengler have recently published a collection of his writings as a presentation to him on his fiftieth birthday. Several articles appear in this volume which have not been previously published, and the whole forms interesting reading and a valuable addition to the present knowledge on tuberculosis and syphilis, though we ask our readers to receive the results of employing "I.K." with reserve for the present.

A MUCH STUDIED PEOPLE.

IT is necessary to go back but very few years in the literature of Egyptology to appreciate the extraordinary revolution which has taken place recently in our knowledge of the people who lived and fought, who built temples and raised monuments, and finally died and were embalmed in ancient Egypt. But a very little while back anyone who desired to gather information concerning the actual physical remains of the ancient Egyptians would have found in the literature little save the records of the examination of individual mummies and the comparison of the findings with the accounts of embalming as given by Herodotus and by Diodorus Siculus. To-day it is very different: an extensive and specialised literature has sprung up, a vast amount of work has been done, and all the search-lights of modern medical science have been turned on the ancient dead of Egypt and Nubia. With most of these more modern studies we have already dealt in our columns, but it would seem that the time has arrived when some inventory might be taken of our knowledge of the people whose remains, though now the subjects of scientific medical inquiry, have so long been reserved merely for mysterious speculations or museum curiosity. The scientific study of the mummy has ever been in the hands of medical men, and it may be said with truth that it has been the medical man, and not the professed Egyptologist, who has learned the secrets of the arts of embalming as practised in ancient Egypt, and who has given us trustworthy data concerning the physical condition of the embalmed. More than 200 years ago Greenhill wrote his "Art of Embalming" and established himself as an authority on mummies. In his train there followed a number of members of the medical profession. In 1825 Dr. A. B. Granville wrote his "Essay on Egyptian Mummies," and nine years afterwards Dr. T. J. Pettigrew published a work which is a monument of accurate observation. Dr. Pettigrew's "History of Egyptian Mummies" reached the high-water mark of researches on the methods of embalmers; for several years no additions were made to real knowledge; and many who essayed the task fell into grave errors which Dr. Pettigrew had avoided. The modern period of research dates no further back than the last 15 years or so, when Professor Alexander Macalister showed the methods by which the physical characters and the mode of preparation of mummies might be studied according to the requirements of modern science. Since then the study of the mummy has made extraordinary progress. Professor G. Elliot Smith and his co-workers in Egypt and Nubia have enormously elaborated methods and perfected research, and by the examination of a vast amount of material have placed our knowledge of the methods of embalming employed at different historical

periods upon a very sound basis. The study of the mummy as an embalmed corpse is well-nigh perfect; so perfect that a high degree of specialisation has of necessity arisen among later workers. The chemistry of the mummy, and of the embalming substances, has been repeatedly dealt with in recent years by Mr. A. Lucas and Dr. W. A. Schmidt of Cairo, and by Dr. Paul Haas and others elsewhere. The gross manifestations of disease as displayed in the bones and the shrunken soft tissues have been fully described by Professor Elliot Smith, Dr. F. Wood-Jones and Dr. Douglas E. Derry in the reports and bulletins of the Nubian Survey. We have already noted in our columns the advent of these stages in the progress of the study of the mummy, and now a later phase is added, for the tissues of these ancient dead have been rendered amenable to the ordinary processes of microscopical examination and have been made to yield up further secrets. Dr. Marc Armand Ruffer has made this study his own, and by the publication of his "Histological Studies on Egyptian Mummies"[1] has given us a very full account of the microscopical appearance of the tissues of these ancient peoples, even demonstrating the nuclei of cells which have been dead for some 8000 to 12,000 years or so. Despite the many vicissitudes of the corpse, both before and after mummification, a very wonderful degree of preservation of minute structure is present, for striation of the muscular fibres in a meal composed of flesh has been detected in the intestine of an individual who died a thousand years before Christ. These and other astonishing instances of the wonders of preservation of delicate histological structure Dr. Ruffer has made clear, and it must be owned that it is an astonishing thought that not only the nerves themselves, but even the minute arteries supplying them, are capable of being examined as thoroughly in the body of a man dead for thousands of years as in the subject of a post-mortem examination of to-day. As we have already noted, Dr. Ruffer has not confined his researches to normal mummy tissues, but has broken fresh ground in the question of the pathology of the ancient Egyptian. His latest contribution, which is published in conjunction with Professor Elliot Smith,[2] deals with Pott's disease and psoas abscess in a mummy of the XXIst Dynasty, a contribution which marks the antiquity of tuberculosis as a human scourge. Dr. Ruffer has struck a profitable line of research in this the last development of the study of the mummy; much material awaits him, and great issues may be at stake.

THE LIQUOR TRADE IN SOUTHERN NIGERIA.

IT will be in the recollection of our readers that, in consequence of the alarming statements which have been made in certain quarters regarding the increase of alcoholism in Nigeria, the Government submitted the whole question to a committee of inquiry, whose report, published a few months ago, gave rise at the time to a good deal of acrimonious criticism. The committee, while finding that the extent of the evil had been somewhat exaggerated, admitted that the increase of drinking amongst the natives was a very real and growing danger. Since then the various missionary and temperance organisations interested in the question have pressed on the Government the need of more energetic action in the matter, and the Secretary of State for the Colonies has recently been waited on by an influential deputation from the Native Races and the Liquor Traffic United Committee, who laid these views before him. Finding that there has been some misunderstanding as to his reply, Mr. Harcourt has communicated to the press a full report of the proceedings, from which we are glad to observe that it is the intention of the Government to put forward strong and drastic proposals for dealing with the whole problem of alcoholism in native races at the International Conference on this question which is to assemble at Brussels next month. With regard to the particular case of Southern Nigeria, Mr. Harcourt was able to give a reassuring reply concerning some, at all events, of the matters which had given rise to anxiety. He was able, for instance, to show that the increased importation of spirits into the country did not mean a larger consumption of alcohol, the strength of the liquor imported having been materially reduced by the establishment of graduated duties differentiating against the more highly alcoholised spirits. The figures which he quoted may be of interest to the advocates of very high taxation as a remedy for intemperance, for it appears that in Nigeria a duty on spirits which amounts to 200 per cent. of their value has not prevented the steady increase of the imports. In this connexion it has, of course, to be remembered that the contact of the native population with industrial Europe is becoming more and more intimate, with the necessary results that the opportunities and the examples of alcoholic excess are multiplied. It is satisfactory to know that the responsible authorities realise to the full the importance of this question, for even those who are least in sympathy with teetotal views will be prepared to agree that the African negro must be protected from the abuse—as he is incapable of the use—of distilled spirits.

THE TUBERCULIN TEST IN CATTLE.

IN the *Illinois State Register* of August 9th, the views of Dr. James A. Egan, the secretary of the Illinois State Board of Health, are stated in regard to the use of the tuberculin test in cows. Dr. Egan commences by conceding that when intelligently and properly applied by a person skilled in its use, and with a working knowledge of diseases of cattle, the test is one of the best means of diagnosing tuberculosis in cows, but he affirms that he is opposed to its indiscriminate application. His chief objections are that it is positive in the presence of the slightest infections which may never spread to the udder, and that it may, on the other hand, be negative and fail to disclose a case of generalised tuberculosis in which tubercle bacilli are being passed in the milk. He is therefore of opinion that dependence on this test may lull authorities and the public into a sense of false security, and he urges the wisdom of examination by competent veterinarians to discover disease, to enforce cleanliness, and to order the segregation of animals clinically tuberculous or with suspicious abnormality of the udders. A large amount of evidence has now accumulated in regard to the uses and limitations of the tuberculin test both in man and animals. It is generally recognised that the test may be negative in miliary tuberculosis, in advanced cases, and in tuberculous meningitis, and that it may be positive in quiescent or clinically inactive lesions. It is, moreover, obviously inapplicable when there is fever. In spite of these limitations it is a useful test, and, according to Mohler in a Bulletin presented to the Public Health and Marine Hospita Service of the United States in 1908, it affords accurate diagnosis in 97 per cent. of cases in cattle. We agree with Dr. Egan that it would be unwise to rely upon this test only and we endorse his plea for intelligent and skilled examination of the cows as well, but if the test were carried out by competent veterinarians this would be ensured. We do not agree that the physical examination should alone be relied on to the exclusion of the tuberculin test or that only clinically tuberculous cows should be excluded. The ultimate object of hygienic measures in regard to the milk-supply is the eradication of the disease, and it is generally admitted that

[1] Mémoires présentés à l'Institut Egyptien, tome vi., fasc. iii.
[2] Zur historischen Biologie der Krankheitserreger, Part 3, 1910.

this is not easy to recognise in cattle in the early stages by physical examination only. It is also important to note that the experiments of the Royal Commission on Human and Animal Tuberculosis proved that bacilli may be present in the milk of cows with tuberculosis but showing no evidence of disease of the udders.

MR. B. TILLETT AND THE MEDICAL PROFESSION.

THE newspapers of Sept. 8th will be found to contain a full report of a somewhat stormy meeting of the Trades Union Congress, at which certain resolutions were moved connected with proposed amendments of the National Insurance Bill. These included a demand for "a medical court to deal with and punish medical officers for misconduct, neglect of duty, or excessive charges." Ostensibly seconding these resolutions, Mr. B. Tillett, well known as a labour leader in connexion with disputes affecting dock labourers, made an attack upon the medical profession which, we believe, few of his followers in their saner moments would hesitate to condemn. Apparently Mr. Tillett desired to express and to emphasise his apprehension lest under Mr. Lloyd George's scheme the medical man should corruptly declare men fit for work who were in fact unfit. He is reported as having said that: "Now the doctor was brought in, with the result that the employer could pay more to the doctor, and could buy up the scientific genius of the medical profession with more facility than he could buy up the lawyers. Whatever one might say against the legal profession in its unscrupulousness should be multiplied in referring to the doctors. They had had hundreds of cases where a doctor had sworn against his own knowledge and there had been no court to remove him from his position. Men had been pronounced thoroughly fit for work, and they died within a day or a week of the pronouncement. Medical officers were in the pay of firms, and they prescribed according to their payment." More of this sort of trash will be found in the papers (we quote from the *Daily Telegraph*), but it need hardly be repeated here, and it is scarcely necessary to point out that what has been cited is on the face of it absurd. If out of the "hundreds of cases" referred to any one example had been susceptible of proof there would have been no difficulty in discovering a court with ample power to "remove" the "doctor who had sworn against his own knowledge" by imprisoning him for perjury. If a man "pronounced thoroughly fit for work" goes back to work and dies next day or within a week, there is, in the discretion of the coroner, ground for an inquest, as the case in such circumstances must come suspiciously near to one of "sudden death whereof the cause is unknown." If medical officers "prescribe according to their payment," Mr. Tillett has no reason to quarrel with the provision whereby patients under the Bill are to choose their own medical attendants. However, there is no need to labour the matter. The working classes, as a whole, are not likely to deny their debt to the medical profession. The work done by it for them has been openly and indisputably charitable where it has been done in, and in connexion with, the voluntary hospitals. It has been less admittedly and ostensibly charitable, but none the less so in fact, where it has been performed with little or no hope of payment under the guise of private practice among the poor. It has been done by members of a profession, who, in acquiring the skill and knowledge which qualify them to practise, have expended money and worked for many years without being able to earn a penny at an age at which the working man's son is supporting himself in independence. It has been the work of a profession which has made no claim for an eight hours day, or for "time and a half" payment for "overtime," but has been, and is, at the beck and call of the sick and suffering during the night as during the day. Mr. Tillett has no reason to be proud of the use that he made of his unquestionable talent for public speaking upon the occasion to which we have referred.

LEAD POISONING FROM GUNSHOT WOUNDS.

IT is remarkable that among the many cases of gunshot wounds in which projectiles were retained in the tissues very few cases of lead poisoning have been observed. The subject appears to have first received attention in the sixteenth century from Ambroise Paré, who noted the innocuity of leaden projectiles retained in the tissues, and to explain it drew a parallel with the healing effect of lead on ulcers. At a recent meeting of the Société Médicale des Hôpitaux of Paris M. Ribierre and M. Flandin reported the following case. A stone sawyer, aged 26 years, was admitted into the Cochin Hospital under the care of Professor Chauffard on May 15th, 1911. In 1903, while in Algeria, he suffered from malaria. On returning to France he had three or four attacks in 1904. He never suffered from syphilis. In July, 1910, he attempted suicide with a fowling-piece charged with No. 6 shot, which entered a little below the right nipple and passed through the chest and the scapula to the wound of exit. The immediate result did not appear to have been serious, but hæmoptysis took place for a fortnight. From the wounds of entrance and exit reddish serum and then pus discharged. After a month there remained only a sinus in the back, from which ten shot were discharged. Three months after the attempt he was seized with violent colic, bilious vomiting and obstinate constipation. The colic continued for two or three weeks and was followed by jaundice with decolouration of the fæces which lasted a month. A fortnight later—six months before admission—paralysis began. When he tried to get up his legs gave way, and his arms were so weak that he could with difficulty carry a glass to his lips. In a few days the arms were completely paralysed and a little later the legs. He remained in bed completely immobilised for three months. Under massage he regained some power in the legs and more slowly in the arms. On examination the deltoid, triceps, and biceps were atrophied but not paralysed. The flexors of the forearm were atrophied, but contracted feebly. The extensors of the wrists and fingers were completely paralysed. The muscles of the lower limbs were weak and atrophied, but he could walk easily. The patellar and tendo Achillis reflexes were diminished. There was no line on the gums. At the wound of exit there was a sinus from which a little seropus trickled. Radioscopy showed numerous particles of lead beneath the right scapula, which moved with this bone, and others, smaller and less numerous and deeper, which moved with respiration and were certainly situated in the lung. The surrounding lung for the distance of a finger-breadth gave a shadow. Blood examination showed 3,399,000 red corpuscles and 12,600 white corpuscles per cubic millimetre, of which 67 per cent. were polynuclear. Lead could not be found in the urine by electrolytic examination, but on treating pus from the sinus with ammonium sulphide blackish-grey granules were observed in all the leucocytes. Under sulphurous baths and galvanisation of the muscles of the upper limbs marked improvement took place, but drop-wrist persisted. It seems that the cartridge used by the patient contained about 250 shot, weighing together 30 grammes. He said that not more than 20 shot were discharged from the sinus. In view of the improvement operation was not thought advisable, but recurrence of intoxication may render it necessary at a future time. Only seven cases of plumbism due to retained leaden projectiles appear to have been

recorded, all by French and German writers. The first was reported by Bronvin.[1] A child, aged 13 years, received in the right hand the charge of a fowling-piece. Two shot were immediately extracted from the wound. Suppuration followed and the wound healed in seven weeks. Shot could be felt beneath the scar. Eight weeks after the accident there were intense colic, obstinate constipation, and a blue line on the gums. Two more shot were extracted, but attacks of colic continued for more than a month, after which recovery took place. Kuster and Lewin have reported the case of a German officer who was shot in the right knee during the war of 1870.[2] The bullet was not extracted, and during the following eighteen years he complained only of pains in the knee. In January, 1888, he began to suffer from attacks of colic with constipation, anæmia, jaundice, and tremor of the hands. There was a blue line on the gums which disappeared from time to time, and lead was found in the urine. At the end of a year the tibia was trephined, andextending from the periosteum to the marrow tracks of little blackish-blue masses were found. After removal of these recovery gradually took place.

UNVENTILATED BEDROOMS.

IN an exhaustive report on the sanitary condition of Hackney for the year 1910 Dr. J. King Warry, medical officer of health of the district, has an interesting and suggestive note upon the frequent use of inadequate rooms as sleeping-places in the small flats which compose what are known as "tenement houses." According to what he has observed in the borough there are in many tenements, not otherwise ill-built or defective, tiny chambers intended presumably for bedrooms, but corresponding in structure to "a ventilated and lighted box-room." They are small, lighted by an ordinary sash window, and provided with a hole in the wall about six inches square which is guarded outside by a grating, but they have no fireplace. In Dr. Warry's experience one of these closets was used by a small boy suffering from measles, and his mother, after stopping up the hole in the wall, had lit an oil-stove in order to provide warmth. This case, it is pointed out, illustrates the need for a fireplace and chimney if such rooms are to be made use of for living purposes. On other occasions Dr. Warry found that one or more of the children of a family were assigned a room of the kind described as a sleeping-place, and that the blocking of the ventilating hole was a frequent practice. He has endeavoured to discover any legal means for discouraging the construction of such rooms, but does not find that he is assisted by any Building Act or other statute or regulation. All will agree that the matter is of some importance, particularly as inadequate accommodation such as that described is usually assigned to children or to a servant, usually a young girl, where one is kept. In this connexion, however, it may be mentioned that the provision of ill-ventilated and insanitary sleeping-rooms for members of the household whose position precludes them from protesting is not confined to tenement dwellings built for the working poor. In many comparatively important and otherwise ostentatious flats the servants' bedroom is wholly unfitted for its purpose, and although its air space and means of ventilation would be insufficient for one occupant it is often made to serve for two. They do not complain; domestic servants do not "strike" against stuffy, dark, and insanitary sleeping rooms with a tiny and perhaps equally gloomy kitchen to sit in, but want of knowledge and foresight on the part of those who have built flats and small houses is probably responsible for a great deal of the difficulty which their tenants find in obtaining and keeping for any long period servants of a decent class. The question of sleeping accommodation so far as it affects servants seems to us, however, to be a matter for the consideration of employers, at any rate, so far as these are of the "upper" and "middle" classes, rather than for legislation. With regard to the homes of the working-classes, including those which have been built since the serious consideration of sanitation and hygiene has occupied the legislature, it must be borne in mind that the undesirable conditions, to which we have at times drawn attention, are not entirely due to defects or to omissions of a possibly intentional character in Acts of Parliament. Rooms built with provision for ventilation, frequently are rendered useless by the deliberate action of their occupiers. The ventilating holes certainly might be increased in numbers or size in small rooms and fire-places with chimney flues might be added, but we hardly conceive that the tenants would, or could, afford fires as a rule in their children's sleeping rooms, and a flue regarded as a ventilating shaft only is just as easily blocked as a hole in the wall. Indeed, the closing of unused chimney flues is a practice not confined to the working classes, if it exists generally among them. What is required is a wider recognition of the advantage or necessity of fresh air as conducing to health, a recognition which is increasing, and which we have no doubt will become more general as children educated in modern schools grow up.

THE TREATMENT OF CONSTIPATION.

IN another column we publish an article by Sir James Sawyer drawing attention to certain points in the treatment of constipation. There is now a tendency to at once proceed to the administration of drugs when dealing with cases of chronic constipation, and to rely on their action alone rather than to bring into force those provisions which nature supplies. Various old therapeutic measures are apt to be lost sight of, and medicaments are substituted for them which sometimes tend to increase the evil rather than remedy it. To "solicit a daily evacuation of the bowels," as the late Sir Andrew Clark was wont to impress upon his patients, is certainly a useful maxim which is likely to be neglected in the daily busy rush of a business man's life; nevertheless, as Sir James Sawyer observes, by long-continued habit in health the act of voiding fæces can become to some extent a rhythmical process, performed at a fixed time by an acquired periodicity each 24 hours. It will be generally acknowledged that before prescribing drugs every care should be taken to inquire carefully into each patient's daily mode of life, so as to endeavour as far as possible to produce the desired effect by habit, diet, or simple mechanical means, such as physical exercises or massage. Sir James Sawyer rightly urges that no case of habitual constipation can be treated by "rule of thumb," and if drugs are resorted to, it is wise to vary the remedy occasionally, as frequently a patient appears to become immune to the action of one particular laxative or purgative. However, there are exceptions, and occasionally a case occurs of the same combination of drugs being satisfactorily used for many years without any change in the prescription. A similar principle here exists as in the treatment of other maladies. A study of the personality and possible idiosyncrasies of each patient must be observed, for it is only by a due perception of every circumstance that successful treatment ensues. Neither Sir James Sawyer's teaching nor our comment contains a word which is not well known to all medical men, but the main lesson to be drawn is rather for the public than for the medical profession. The public in increasing numbers love to change their regular medical attendant for some one

who is supposed to be "good" at this, that, or the other class of case. It wants to be impressed upon them that a prolonged and detailed acquaintance with a patient has a diagnostic value "in all things great and small."

THE ETIOLOGY OF BERI-BERI.

THERE is probably no disease concerning which so much discussion as to its etiology has taken place as beri-beri. In the elucidation of the mystery concerning it, Dr. Henry Fraser and Dr. A. T. Stanton of the Malay States have just published the results of an extremely painstaking and exhaustive research, and it would seem opportune to draw attention to the many hypotheses concerning its nature (p. 828). They, as will be seen, are various and conflicting; some which would appear to be convincing from the positive nature of the data on which they rest, are succeeded by others resting on equally valid grounds. The late Dr. Kynsey, formerly Inspector-General of Civil Hospitals, Ceylon, held that one form of the disease was due to the presence of ankylostoma, and possibly also of trichocephalus dispar, the effect of these worms accounting for the anæmia present in the disease.[1] The germ theory has been invoked; thus Pekelharing and Winkle claimed to have discovered a specific bacterium; H. V. Dangerfield of Réunion also described a bacterium having five stages of evolution—namely, a hemispherical, a diplococcic, a micrococcic, a zooglœic, and, finally, a sporulating form; Ogata in Japan isolated his kakke coccus, whilst later Tsukuki announced the discovery of the specific diplococcus of the disease. Then we have Manson's theory that the disease is produced by a toxin from a germ whose nidus is outside the body. He aptly compares the position with that of alcoholism thus: In the case of alcohol the germ is the yeast plant; the nidus solutions of sugar; the toxin the alcohol; and the pathological effect a peripheral neuritis. In beri-beri the saprophyte produces a toxin; the nidus is the soil or surroundings; the man is poisoned, and as a pathological effect suffers from a peripheral neuritis. A striking example in favour of this theory was furnished in 1895 by Dr. Travers at Kuala Lumpur. Here there were two jails. In the old one the disease had not appeared, but after a new additional jail had been built an extensive epidemic arose in it. The rice supplied to both jails was the same. On transferring the sick from the new jail to the old one they rapidly recovered. The late Dr. Norman Chevers held the view that has been followed and amplified by Dr. Hamilton Wright. They hold the disease is consequent on a bacillus being taken into the human organism with the food; after incubating for about ten days a specific duodenitis is produced, and from this the nerve poison is developed. Wright states this affection of the duodenum always shows itself at the commencement of the illness. Yet another hypothesis lays the blame on certain metallic elements. Amongst these may be mentioned arsenic and oxalate of potassium; whilst recently Staff-Surgeon A. J. Laurie, from his experience on the *Sphinx*, incriminates copper. Lastly, we come to the hypotheses connected with the diet, and it is with these hypotheses that the most convincing work has been done. Some hold that the disease is due to a deficiency of fat in the diet. Dr. Brémand showed how an epidemic at Poulo Condor ceased suddenly under the influence of a regimen containing fat pork. A most convincing theory, however, is that connected with the deficiency of nitrogen in the food. Baron Takaki, when surgeon-general of the Imperial Navy of Japan, furnished a most striking proof of this factor, and by his ordinances seems to have eradicated the disease from that navy. In 1880 he noticed the great disproportion between the number of cases occurring in warships and those in barracks, and thought this might be due to the difference in the food on board ship and on shore. He held that in the naval dietary there was an excess of carbohydrates and a deficiency of proteid. In 1883 the warship *Ryujo* made a voyage of 271 days to New Zealand, and 160 cases of beri-beri occurred out of 350 *personnel*. By his influence the ship *Taukuba* made the same voyage under the same conditions, but with an improved dietary, avoiding the excessive use of rice. The *personnel* in number were about the same. The result was that only 16 cases of the disease occurred. This significant result was followed by elimination of the disease from the Japanese navy, so that during the war with Russia it was free from it, although the army suffered considerably. Comparing now the ratio of the disease in the Japanese navy in different years: in 1882 the ratio per cent. was 40·45; in 1889 it was 0·03. The latest researches in regard to the food factor have just been published by Dr. Fraser and Dr. Stanton; much of the work has already appeared in our columns, but we welcome it in volume form. Their results may not prove that a certain condition of the rice is the *only* cause of beri-beri, but they certainly do prove it is one cause. They show that white polished rice will cause the disease; that when fowls, on the contrary, are fed on unpolished rice they do not contract the disease; and, finally, that if the polishings from white polished rice be added to a diet of white polished rice beri-beri does not result. This experience is confirmed by that found previously in the prisons of Java. In those jails in which white rice was consumed 36 out of 51 were affected; whereas in those using red uncleaned rice only 1 out of 37 jails was attacked. These researches coincide to a great extent with the opinion of Dr. Hébrard, who has just published his views on the disease. We may also mention that in 1896–97, and again in 1906, Professor C. Eykman of the University of Utrecht published the results of his researches into the question of the factor of rice in beri-beri, in which he proved that an extract from rice polishings if added to white polished rice cured sick fowls of polyneuritis. To complete the theories implicating diet as a factor, it may be mentioned that Gelpke incriminates a dried fish infected by a trichina; Grimm, infected fish generally; and Miura, raw fish. These causes, however, can be excluded at Kuala Lumpur, where in 1901 for eight months no fish was included in the diet of the prisoners who during this time contracted the disease.

[1] Dr. Noe found in 74 out of 77 cases the eggs of the Uncinaria americana, and consequently holds that this nematode plays an important part in the etiology of the disease.

THE late Dr. Samuel Gee, whose will has now been proved, left the residue of his estate, amounting to about £20,000, to his daughter for life, with contingent remainder to the Royal College of Physicians of London upon trust, as far as possible, to form a permanent endowment fund for the College.

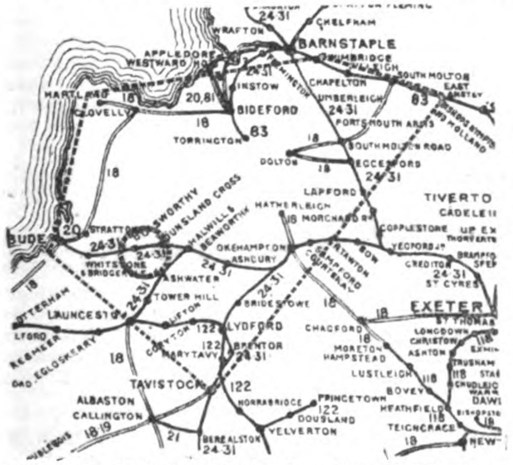
Dr. D. Fraser Harris, lecturer on physiology in the University of Birmingham, has been appointed to the newly founded chair of Physiology at Dalhousie University, Halifax, Nova Scotia.

DEATH OF MR. HORACE NUTT.—Mr. Horace Nutt, who died at his residence, Brooklyn House, Sherborne, Dorset, on Sept. 6th, in his seventy-third year, qualified as M.R.C.S. in 1861 and had been for many years in practice at Sherborne, where he was for a long time medical officer of health. He was also medical officer and public vaccinator of the Sherborne Union, and for the past 35 years has been coroner for the Hundred of Sherborne and Yetminster, an office which carried exceptional justiciary powers. Mr. Nutt was, it is said, the last of the "Liberty Coroners." He was very popular in Sherborne and the neighbourhood.

"SPOTTED FEVER" AND ACUTE POLIOMYELITIS IN DEVON AND CORNWALL.

(FROM A SPECIAL CORRESPONDENT.)

EARLY in August a notice appeared in one of the Devon papers of an outbreak of "spotted fever" in the area around Holsworthy. Later in the same neighbourhood cases were recorded of acute poliomyelitis, and in the public mind some difficulty appears to have arisen in diagnosis. The first cases occurred seemingly some months ago, but little attention was paid to the matter, and, as usually happens, initial neglect has apparently enabled the disease to spread over a wide area of an irregular pentagon in shape. Starting at Bude on the west, the sides pass north and slightly east to Hartland, east and slightly north to Swimbridge, east and slightly south to South Molton, south-west to Tavistock, thence north-west to Bude. At a point within the Bude angle is Holsworthy. The accompanying map is from Townsend's "Western Counties Railway



Map showing (1) the area around Holsworthy; and (2) the area of irregular pentagon shape marked by a dotted line, within which the epidemics have occurred.

Guide," the figures referring to the paging of that guide. There is no direct intercourse between the centres involved, the market towns being in quite different directions.

The Situation at Holsworthy, &c.

Dr. R. J. Reece, a medical officer of the Local Government Board, was sent down by that Board to make a special investigation, and he has held private consultations with local medical officers of health and local health authorities, together with the county medical officer in various centres. The Holsworthy urban council hardly seemed to realise the necessity for taking efficient measures at the onset to prevent an epidemic and the danger of waiting until "one or two doubtful cases" were followed by a widespread outbreak.

At a meeting of the council held on August 8th, after what residents called "the scare in the papers," an animated discussion took place. The medical officer of health, Mr. W. G. Gray, was charged with having given rise to the scare by supplying information to the press, but he denied this. Mr. Gray said that the first case of cerebro-spinal fever (though not recognised as such at the time) took place at Clawton in the first week in May. He described the case and referred to seven other cases. He advised—(1) the distribution of leaflets calling attention to the symptoms of the disease and urging that medical advice be at once sought whenever they were found; (2) compulsory notification; (3) the inspection of all school children before reassembling; (4) official disinfection of all houses and clothing when the disease has died out; (5) the erection of isolation sheds near a cottage that could be used for administrative purposes. Mr. George Adkins, medical officer of health of the county of Devon, who was present, supported the recommendations, as did also Dr. Reece.

In spite, however, of the definite advice of three experts, the resolution in favour of notification was carried only by the casting vote of the chairman. The council declined to make provision for the isolation of cases. After this experience at the urban council, Dr. Reece found it necessary to speak at the meeting of the Holsworthy rural council, held the next day. He told the council it had in its district cases of an infectious disease that killed people. There were probably some thirty cases inside that district alone. The disease extended to at least three other sanitary districts in the neighbourhood, and probably, he believed, more. He did not think that the outer limit had yet been reached. Both cerebro-spinal meningitis and acute poliomyelitis required to be treated as cases of infectious disease—i.e., a disease which should be isolated and contacts disinfected. Sometimes there were one or two cases in a house, no medical man was consulted, and the cases multiplied and assumed a serious aspect. It was not only a direct question of loss of life—about 10 per cent.—but a very considerable proportion of patients were left paralysed, often permanently, and some were deprived of speech, hearing, or sight. It was as important, he said, to notify minor cases as it was the more severe ones.

Mr. Gray said that two deaths had been certified as due to cerebro-spinal fever, and there were two other deaths in which the certifying doctor had some doubt. Mr. Gray took further occasion to protest against the unfair treatment meted out to him in charging him with giving out information to the press. In point of fact, he had declined to accede to such a request from a London paper until after his report should be presented to the council. It then became a public document, and copies had been sent in due course to the Local Government Board and the county council. The council adopted notification *nem. con.* On August 10th a labourer, aged 30, died from spotted fever at South Wonford, Thornbury.

Mr. C. C. Brodrick, medical officer of health, at a special meeting of the Tavistock rural council on August 18th, reported two cases of spotted fever in the district; one fatal one near Broadwood Widger and the other on the Launceston side of the district. Spinal fluid from the latter case was sent to Dr. M. H. Gordon at St. Bartholomew's Hospital, who replied that it was undoubtedly a case of spotted fever. It was unanimously resolved to make spotted fever notifiable for six months, and it was decided to obtain a cottage and canvas screens for isolation purposes, and that a printed description of the symptoms of the disease, with instructions how to act, should be circulated among the public. The chairman, the medical officer of health, and the clerk were appointed a subcommittee to carry out this resolution.

Lack of Facilities for Hospital Isolation.

On August 23rd Mr. Gray reported to the Holsworthy rural council that since the last fortnightly meeting altogether eight cases of cerebro-spinal fever and infantile paralysis had been reported. Two had died and a third case would end fatally within 24 hours. The cases were scattered. The origin of the outbreak was unknown. The present isolation cottage was too dilapidated for use. He produced photographs and said that four inches of water stood in the inner room, although it had not rained for a month. The council, however, decided to defer consideration of the question of isolation accommodation for a fortnight.

With reference to this "let-it-slide policy" the *Bideford Gazette* said: "The adjoining districts are vitally affected, and if Holsworthy will not isolate their cases for their own protection it will become the duty of the adjoining authorities, in self defence, to appeal to the Local Government Board to bring the necessary pressure to bear upon them to make them do so for the sake of others."

Unfortunately, Holsworthy is not the only district in Devon where there is no provision for isolation, as appears from an inquest held at Hartland on a man aged 70, who died there on August 31st after a few hours' illness. At 1.30 P.M. he complained of pain in the stomach and a neighbour gave him ginger tea and helped him to bed. He was seen alive at 4, but was dead by 5 P.M. Dr. A. F. Wright said there was recent inflammation at the base of the brain and that turbid fluid came from the cord. He considered that the conditions found were not sufficient to cause such a sudden death. A verdict of "Death from natural causes, syncope," was returned. One of the jury criticised Dr. Wright for having taken a case of poliomyelitis into his own house. The doctor explained that a midwife at a case was seized with the disease, that the people at her lodgings would not take her

back, and, as there was nowhere else she could go, he had turned out of his own house and put the patient in.

As there is no isolation hospital for the Bideford rural district, in which Hartland is situated, the comment of the local paper certainly appears justified:—

It does seem nothing short of a public scandal that the medical man, because he happens to follow his profession in an isolated place like Hartland, should have to take upon himself the duties which ought to be carried out by the sanitary authority. It is most ungenerous that his kindly and Christian action should be criticised as Dr. Wright was by some of the jury.

Hartland, which is a very small village in the extreme north-west of Devon, has had four other cases of acute poliomyelitis, occurring in a married woman and her three children.

Progress of the Outbreak.—Some Difficulties.

At South Molton a child is reported to have died from spotted fever on August 12th, and a boy, aged 15 years, taken ill on August 28th, died from acute poliomyelitis on August 30th.

At Barnstaple rural council on Sept. 1st Dr. H. C. Jonas, deputy medical officer of health, reported a fatal case of acute anterior poliomyelitis at Swimbridge. The boy, after a visit to South Molton, went on to Exeter, and was there taken so ill that he was carried to the train and taken home to Swimbridge on August 26th, where he died the next day. All the medical men in the district have been notified of this case and contacts have been traced.

It seems impossible at the present date to follow out the progress of the outbreak, many links in the chain are as yet unknown to us. For example, it is not certain that even all the fatal cases are included in this account. Two other difficulties are present; the distances from centre to centre and the absence of suitable isolation accommodation. Measured on the map in a straight line, Holsworthy to South Molton is 26 miles N.E.; to Broadwood Widger, 10 miles S. by E.; to Hartland, 16 miles N. by W.; to Penryn, 56 miles in a straight line S.W.; to South Wonford, Thornbury (Devon), 4 miles N. by E.; Hartland to South Molton, 28 miles E.; Penryn to South Molton, about 80 miles.

At Dartmouth town council on Sept. 4th Dr. J. H. Harris, medical officer of health, recommended that cerebro-spinal fever and acute poliomyelitis should be made notifiable for a year, but Alderman Row said that "that meant fees," so the question was referred to a committee. It is a pity that the council did not adopt the recommendation at once; delay in such matters may probably prove much more serious than "fees." Owing to the presence of poliomyelitis all the schools in certain of the parishes have been closed for one month from Sept. 4th or until notice.

The Question of Isolation Hospitals.

At Bideford rural council on Sept. 5th Dr. L. B. Betts, medical officer of health, reported four cases of infectious acute poliomyelitis from Hartland and one from Woolsery. He advised that a conjoint infectious diseases hospital should be provided by the various authorities in that portion of North Devon, and he reminded them that Dr. Wright at Hartland had had to isolate a patient in his own house. The chairman said the council had discussed the question over and over again. Owing to the scattered nature of the district the provision of a hospital was a difficult matter, as Dr. Reece had appreciated. The port sanitary hospital ship was suggested, but it was almost certain that the port authority would not agree. All the surrounding councils have tried in the past to put off providing isolation hospitals because of the presence of the hospital ship. On two occasions the ship was used to isolate cases from shore, but the port authority decided that they would not allow it again. An emergency committee was appointed, with power to act in case of further need.

Some nine years ago Northam council had a conference with Bideford rural council to arrange, if possible, for the erection of a conjoint isolation hospital, but no agreement could be effected and the matter dropped. The necessity for proper isolation has been pointed out time after time by inspectors from the Local Government Board and by medical officers of health. Now some sort of provision must be made in a hurry to tide over the present emergency or the people will have to be left to shift for themselves, as in the case at Hartland. There is a good isolation hospital belonging to Bideford urban council, and Northam council has a small building which, however, hardly answers modern requirements. Holsworthy seems to be waiting to see if the epidemic will last.

The provision of a conjoint infectious hospital for the Tavistock urban and rural councils has fallen through, as certain details could not be agreed upon. If infectious hospitals are necessary it is incomprehensible why so many local authorities keep postponing the matter. The extensive area comprised in the districts of Tavistock and Holsworthy and Bideford rural district is now face to face with a serious problem which cannot be solved in time to be of real use in preventing the spread of this epidemic outbreak. It is to be hoped that the various councils will at last see the advantage of being prepared beforehand. The Tiverton councils have a conjoint infectious hospital, and other examples are to be found Mr. Gray of Holsworthy recently found himself in a difficult position. A child contracted acute poliomyelitis and the mother was expecting her confinement. There was no means of isolation in the house. The council at their previous meeting had put off providing any isolation accommodation, so Mr. Gray bought a portable shelter on his own responsibility for the woman. The council decided to pay the cost, £15. The child has since died.

Adoption of Notification.

A fresh centre has started at Westward Ho, where it became known on Sept. 6th that a boy, aged 9 years, had poliomyelitis. On Sept. 5th Penryn (Cornwall) town council resolved:—

That acute poliomyelitis having appeared within the borough, the provisions of the Infectious Disease (Notification) Act, 1889, shall extend to acute poliomyelitis and cerebro-spinal fever.

This resolution will not come into force until Sept. 15th, or at least a fortnight too late. The history of the present outbreak shows clearly the real necessity of making these two diseases permanently notifiable all over the kingdom, and it would be well if the Local Government Board would take steps to do so as soon as possible. Buckfastleigh urban council has proposed to adopt the section permanently. Several other councils have adopted it for six or 12 months.

Outbreaks of Acute Poliomyelitis.

At South Molton rural council on Sept. 8th Mr. H. M. Body, medical officer of health, reported that five cases of poliomyelitis had been notified in the district. The children had not visited or come into contact with any persons connected with other cases. The patients were three miles from one another, and there had not been two cases in any one school. He recommended that persons in contact with the disease should spray their mouth and nose with a solution of permanganate of potash. He stated that it was possible for a person to convey the germs several miles to someone else without himself contracting the disease, which he (Mr. Body) considered might be conveyed through the air.

At a meeting of the Devon county education committee on Sept. 8th Mr. G. Adkins, county medical officer, gave some particulars of the outbreak of acute poliomyelitis in various parts of the county. He had closed 25 schools. The disease was present in 12 out of the 52 districts of the county. There were 80 cases altogether, and 16 deaths had occurred. A great many children were permanently paralysed. One medical man had 35 cases. In reply to a question Mr. Adkins said that three definite cases of spotted fever were known amongst those reported.

FORTY-SEVENTH ANNUAL REPORT OF THE REGISTRAR-GENERAL FOR IRELAND.

NOTWITHSTANDING the dislocation of routine work which is probably inseparable from census taking, the Irish Registrar-General's report for 1910 has appeared with commendable punctuality—little more than six months having elapsed since the close of the year to which it has reference.

Sir William J. Thompson, whose second annual report is the subject of the present notice, and whose interesting review of Irish vital statistics appears in the present issue of THE LANCET, on p. 809, is fortunate in being able to announce a further improvement in the public health.

Although the rates both of natality and mortality were somewhat below those of the preceding year, the birth-rate in 1910 was slightly higher than the decennial average. Irish mortality, expressed in terms of estimated population, was equal to 17·1 per 1000, and was therefore lower than the decennial average by 0·6 per 1000. Only in two of the previous ten years—namely, in 1905 and 1906—had so low a general rate been attained. This result is due to a fall in the fatality from tuberculosis, the deaths from this cause, in 1910, being fewer by 2678 than the number recorded so recently as the year 1904.

Population Estimates.

The difficulty of estimating the population is exceptionally great in Ireland. Of the effect of immigration on the numbers living no record is available, so that the Registrar-General has no alternative but to base his estimates for each year on the balance of births, deaths, and emigrations, the only other definite factor at his disposal being the number of the people at the previous Census. The population of Ireland still continues to decrease. At the Census taken in April, 1911, the population of Ireland was found to be 4,381,951.

Vital Statistics.

In considering local changes of natality and of mortality it must be borne in mind that the populations employed in framing ratios are necessarily the result of estimation, and experience shows the unreliability of such estimates for periods remote from the Census. Accordingly, when the results of the recent enumeration are available, it will probably be found necessary to revise the published rates of marriages, births, and deaths, especially those for the later years of the past decennium. The deaths registered in Ireland last year numbered 74,894, and were equal to 1 in 58·3 of the population, and to a rate of 17·1 per 1000 estimated to be living at the middle of the year. Disregarding ages, the death-rate among females was slightly higher than among males. Of the total deaths about a fifth part occurred in public institutions. Some idea of the local prevalence of poverty in Ireland may be formed from the fact that the proportion of deaths in workhouses was equal to 17 per cent. of the total in the province of Leinster and to 19 per cent. in Munster, whilst it was less than 11 per cent. in the provinces of Ulster and Connaught. In different parts of Ireland mortality varied widely; the rate did not exceed 13·1 per 1000 in county Clare and 13·2 in County Mayo, but in the county borough of Dublin it amounted to 22·4 per 1000. The relatively low mortality among young children, to which we have previously referred as exceptional, has been maintained in the year 1910. From the present report we learn that in Ireland generally the deaths of children aged 0–5 years did not exceed 33·7 per 1000 living at that age, a rate which is not only considerably below the average in England, but is practically identical with the mean rate in "rural England," as shown by the last issued report of the Registrar-General. At subsequent ages the Irish rates are higher than those of the English rural counties, and in some cases exceed the average rates for England and Wales as a whole.

Infantile Mortality.

Ireland still continues to compare favourably with other parts of the United Kingdom in respect of infantile mortality. In the decennium ended 1909 the rate averaged 97 per 1000 births, whilst in the ensuing year it further fell to 95 per 1000. In the "civic unions," which contain the chief towns, the rate was 123 per 1000, and in the remainder of Ireland it was as low as 75·5; and even this low rate exceeded that of the previous year, which had been only 70·9 per 1000. About one-third of the deaths at this early age were caused by wasting diseases, including premature birth, atrophy, and congenital defects. Other chief causes of death were bronchitis and diarrhœal diseases, which accounted for nearly one-fourth of the total mortality.

Occupational Statistics.

The Irish Registrar-General has this advantage over his colleagues in England and Scotland—that he possesses the means of ascertaining the relative mortality in the various social grades of the community. In the present report the familiar table reappears, showing the mortality at several ages experienced by four sections of the Dublin citizens. Although this table relates to one year only, we believe that similar tables have been prepared for a long series of years. We hope, therefore, to see in some future report a summary of the facts for as many years as possible, for such a summary would be instructive as furnishing an approximate measure of the average mortality in the various social grades of a large urban population. From the present table it appears that whilst in the "professional" and "middle" classes, and, indeed, in the artisan and shop-keeping classes also, the mortality was considerably below the average (22·7), it was very high in the "general service" class, being equal to 27·9 per 1000 among hawkers, porters, and labourers.

Principal Causes of Death.

From a table comparing the mortality in the year 1910 with that of the previous year it will be seen that measles, whooping-cough, and scarlet fever were more destructive than before, whilst there was a fall in the mortality from the other common infectious diseases, as well as from pneumonia and bronchitis. No deaths from small-pox have been registered in Ireland since 1907; nevertheless, the returns of recent years show a dangerous falling off in the number of vaccinations. In the year 1909 only 78·3 per cent. of the infants born had been successfully vaccinated by the end of that year. The number of defaulters has steadily increased since 1905. The loss of life from tuberculous disease in the year 1910 was less than in any previous year. The deaths from all forms of the infection numbered 10,016, and corresponded to a rate of 2·29 per 1000 of the population. Six years ago—namely, in 1904—the rate attained its highest point: it was 2·90 per 1000, or 1·1 per 1000 above the English rate for the same period. Of the total deaths from tuberculosis almost three-fourths were due to phthisis, which caused a mortality of 1·72 per 1000. Taking all ages together phthisis would seem to be equally destructive to both sexes, but when the ages at death are examined the differences are found to be considerable. At ages under 20 the loss of life is exceptionally heavy among females, whilst after that age the greatest loss is sustained by the male sex. In Ireland the age of maximum mortality in both sexes is between the twenty-fifth and thirty-fifth year, or at least ten years earlier than in England. From the occupational mortality table for 1910 it appears that phthisis exacts the heaviest death-toll from commercial clerks and petty tradesmen, who succumb to it twice as readily as do members of the professional class. In order, however, to settle the question of relative occupational mortality from this disease the facts for more than a single year will have to be examined.

Campaign against Tuberculosis.

In Ireland a vigorous campaign against tuberculosis is being conducted by the "Women's National Health Association," which was originally founded, and is still presided over, by the Countess of Aberdeen. Reviewing the causes contributory to the success of the movement, the Registrar-General speaks appreciatively of the work of the association. As tending towards the general improvement of the public health, he assigns particular importance to the practice of diffusing simple health instruction among the masses, which has from the first been adopted by the visiting staff. Among the measures thus advocated may be noted the proper ventilation of dwellings, the observance of personal and domestic cleanliness, the selection and cooking of food, the instruction of mothers and children in the essentials of health, the provision of meals for school children, and the home care of consumptive patients. In the advocacy of these measures the association has willing coadjutors in the medical officers of health, possessing as they do exceptional familiarity with the needs and the home life of the very poor. Among other preventive agencies against consumption the Registrar-General speaks highly of the instructive reports he receives periodically from the local registrars, most of whom are medical men, whose intimate knowledge of the local conditions prevailing in widespread and often sparsely peopled districts renders their coöperation of the utmost value. From a large number of these reports the following may be cited. One registrar says that "owing to the spread of knowledge about tuberculosis this disease is practically stamped out in this district. The cases are now seen early; and, thanks to the intelligent coöperation of patients and their friends with regard to fresh air, disposal of sputum, &c., it is generally possible to arrest, if not cure, the disease in the patient, and also to prevent its spreading to other members of the household."

Another registrar reports that "tuberculosis seems to be losing ground in this district." Yet another registrar remarks that "the infectious nature of tuberculosis is now widely recognised, and also its preventability. The people, until recently, bowed their heads to its ravages and said, 'twas the will of God'! They now see that the 'will of God' lies the other way, the way of sunlight, fresh air, cleanliness, and freedom from disease."

Sir William Thompson concludes his able and instructive report with a graceful recognition of the valuable assistance rendered in its preparation by his colleague, Dr. Ninian M. Falkiner.

ASYLUM REPORTS.

Dorset County Asylum (Annual Report for the Year 1910).—The average daily number on the registers at this asylum was, for the year reported on, 856. There were admitted 220 cases, of whom 55 were private cases. There appears again to have been a very high proportion of the maniacal type among the admissions, in the case of women over 60 per cent., and in the case of men almost 50 per cent. The small percentage of cases of the depressed type is in striking contrast to the records of a few years ago. Amongst etiological factors heredity is again in the ascendancy. In the case of the admissions of 1910 there was a percentage of over 50 in which there was evidence of direct or collateral inheritance. Among other factors enumerated in the causation table that of stress takes a prominent position, and Dr. P. W. Macdonald, medical superintendent, points out that when this is considered in relation to the preponderating influence of heredity, there is a fairly sound basis on which to build a hypothesis of the high percentage of mental disease in this county. He adds; "The inference is simple. In the case of the predisposed all and every shade of pressure should be guarded against, because of the danger of an early breakdown, yet when any suggestion is made to the responsible person the suggestion is either disregarded, or as more often happens, grave offence is the result of true and well-meant efforts to save and protect the predisposed from lasting and irretrievable disaster. Such is the present position; and so long as the concealment of facts predominates, there is little hope for a better or clearer understanding of the true and fundamental facts as regards the causation of mental disease." The number of cases discharged was 87, and of these 64 were discharged recovered, being a percentage of 41·02 on the direct admissions. With relation to divorce and insanity, Dr. Macdonald points out that in certain cases patients recovered after very prolonged periods of illness. For instance, in 1910 one case had been under care for five years, a second for six and a half years, a third for nine years, and a fourth for 23 years. Of those discharged recovered 75 per cent. were placed under treatment within three months of the onset of the attack. This is regarded as a striking proof of the change that has occurred in recent times with reference to the public estimation of the home for the treatment of the mentally afflicted. There is no longer a reluctance on the part of those at home to have their relatives placed under the best possible conditions, and if we could only get rid of the absurd and antiquated words which constitute the so-called stigma, mental disease would be talked of and treated as other diseases. The percentage of deaths to the total number under treatment was 7·7. Dr. Macdonald draws attention to the steady and gratifying continuance of the good results of solaria treatment.

Roxburgh, Berwick, and Selkirk District Asylum (Annual Report for the Year ending May 15th, 1911).—The average daily number on the register for the year was 310·3. There were admitted 61 patients, being 9 more than during the previous year, and 4·4 less than the average for the previous ten years. Sixteen admissions had been previously under treatment in this asylum, the periods of absence ranging from 31 years to seven weeks, the average period of absence being seven years. Among the admissions hereditary predisposition was ascertained to exist in 27 cases (44·2 per cent.). The physical condition of the patients admitted was bad in 55·7 per cent., very bad in 14·8 per cent., and good or average in 29·5 per cent. Thirty-two patients were discharged, of whom 21 had recovered. The recoveries as compared with the admissions gave a percentage of 34·4. Of the 21 recoveries 18 were cases in which the disorder had been of less than three months' duration on the patient's admission, and three in which the duration had been from three to six months. The deaths numbered 23, the rate of mortality on the average number on the register being 7·1 per cent. The mean age at death was 63·8, and the average duration of residence in the asylum was six years and nine months, the periods ranging from seven days to 37 years. Post-mortem examinations were made in 91·3 per cent. of the cases.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

City of Birmingham.—The proportion of notified cases of scarlet fever removed to the city hospitals each year from 1900 to 1908 was between 86 and 90 per cent., in 1909 it had fallen to 78 per cent., and in 1910 was 72 per cent. The remaining 28 per cent (some 750 cases) were treated at their homes, the health authorities being in each case satisfied that the patient could be kept in a separate room. Dr. J. Robertson compares the two groups in regard to the occurrence of secondary cases, and concludes that in this respect the results on the whole were as good when the scarlet fever case was treated at home as when he was removed to hospital. The mortality rates for hospital and home patients respectively were 3·3 and 2·1 per cent. When the scarlet fever case has been removed to hospital and the house disinfected it is the practice to allow any school child in the house to return to school after ten days from the date of disinfection. In considering the sufficiency of this interval Dr. Robertson gives the figures for 1910; 287 cases occurred within 28 days of the removal to hospital of the primary cases, of which 253 occurred in the first seven days and 260 in the first ten days, thus leaving 27 cases (or 9·4 per cent.) which began after ten days from the date of the removal. During the year 591 cases of diphtheria were notified, of which 64 were fatal—a fatality not more than half that prevailing in Birmingham from 10 to 15 years ago. The fatality rate among the 351 cases treated at the City Hospital was 9·7, as compared with 12·9 in the remaining cases. Enteric fever was less prevalent in 1910 than in any previous year. Only 73 cases were reported, and the rate of mortality from this disease was 0·03 per 1000, as compared with the corresponding rate of 0·05 for the whole of England and Wales. As in previous years, mussels came under suspicion as the cause of infection of a considerable proportion of the enteric fever cases. In connexion with epidemic diarrhœa Dr. Robertson insists that in addition to infection which may be attributed to the agency of flies "we must not overlook the fact that the whole of the dust in courtyards, on housetops, and on roads in the poorer neighbourhoods is contaminated with organic matter of animal origin, and that this dirt is carried everywhere by air currents, so that clean, or relatively clean, households in one of the congested districts of the city will possibly get cases of diarrhœa through no fault of the householders themselves." The births registered during 1910 were 14,898, and 9439 births were attended by registered midwives. The cases in which midwives advised that medical help should be obtained under the rules of the Central Midwives Board were 674, as compared with 540 (out of 9238 births) in 1909, and 343 (out of 9244 births) in 1908. Special inquiries were made by the midwife visitor where stillbirths were reported. A considerable number were found to be full-time infants not in any way macerated, indicating that possibly with better recognition of the conditions the child might have been born alive. Visits to the homes of consumptive patients have been further developed. At present there are three visitors who devote the whole of their time to this work in the city, and a fourth visitor is shortly to be appointed. There are some 3000 to 4000 houses in which consumptives reside where visiting is considered desirable. The health department administers two sanatoriums—one at Salterly Grange, with 40 beds for early cases, the other at Yardley-road, with 50 beds, for educational

treatment. The experience of the latter shows that care is necessary to avoid frightening patients, who are capable of resuming their employment, from resuming work when they are fit to do so. Several brass-casters in 1910 objecting to the danger of workshop dust sought other occupation and failed to get it, and thus have had to put up with the worse conditions entailed by extreme poverty. A very instructive report by Mr. J. Malcolm, F.R.C.V.S., shows the steps which have been taken to eliminate tuberculosis from particular dairy herds on Professor Bang's method. Fifteen herds supplying Birmingham with milk, numbering 607 cows, were thus being dealt with at the end of 1910, and there is now in Birmingham a recognised supply of tubercle-free milk from tubercle-free cows. So long as consumers are willing to pay a slight increase in price over that of ordinary milk a supply will be provided equal to the demand, and "it would now appear to rest with the public whether the movement is to progress or not." Mr. Malcolm draws attention to the difficulty which at present exists in securing the slaughter of cows with tuberculosis of the udder, and considers that there would be great advantage in the payment of compensation, even if the scale was very small. One of many satisfactory results to be expected from the forthcoming extension of the Birmingham boundaries is that the slaughter-houses at present on the outskirts will be brought under municipal control and be dealt with by qualified meat inspectors in the same way as the slaughter-houses now in the city. It should be added that this report contains some instructive sections relating to house accommodation in Birmingham and the policy which has recently been adopted by the town council in dealing with slum areas.

Metropolitan Borough of St. Marylebone.—Dr. C. Porter comments on the sale of "pasteurised skimmed milk" in the poorer streets of Marylebone direct from the churn at the price of 2*d.* or 2½*d.* a quart. Having ascertained that this milk was unsatisfactory on bacteriological examination, and cautioned the vendor without producing improvement, Dr. Porter arranged for a churn of milk to be seized and the vendor prosecuted under Section 47 of the Public Health (London) Act. The magistrate condemned the milk on the report of the bacteriologist, who found in it enormous numbers of bacteria, including streptococci, and fined the vendor. Under the Sale of Food and Drugs Act a large increase of sampling took place during 1910, particularly in "informal" samples. A notable amount of milk adulteration and of substitution of margarine for butter was thus detected. Dr. Porter draws attention to the need for amending legislation to secure that all vessels from which skimmed or separated milk is sold should be properly labelled. "Catch of the season" chocolates—articles apparently intended to provide practical jokes—were ascertained to contain cayenne pepper, and were very properly dealt with as dangerous under Section 3 of the Act of 1875. An anti-tuberculosis dispensary was opened at 15, Allsop-place, in November, and was at work before the end of the year. Considerable additions have lately been made to the staff of the public health department in view of increased work in many directions. In referring to public "sanitary conveniences," Dr. Porter states that progress has been made in providing free accommodation for women, and that a "urinette" installed in place of a water-closet at Oxford Circus has been largely used. The receipts of the borough council for the use of public conveniences in Marylebone amount, it would appear, to some £3000 per annum.

Metropolitan Borough of St. Pancras.—In dealing with infantile mortality and vitality Dr. J. F. J. Sykes again insists on the importance of attention to the nutrition of the mother before the birth and during lactation. "Our medical service," he observes, "must be styled not infant consultations, but medical consultations for mothers and infants—mothers first." Some six years ago all leaflets advising methods of artificial feeding were destroyed, and the experiment of persistently preaching and teaching breast-feeding alone was begun. In 1907 the St. Pancras School for Mothers at 37, Charlton-street, Somers Town, was started to provide medical consultations for those mothers and infants unable to secure medical advice, dinners for mothers suckling their infants, and educational demonstrations in "mother-craft" both at the school and in the home. In 1910 this school for mothers extended its work to children up to compulsory school age, with a view of preventing the defects so commonly found in course of medical inspection of schools, and in this direction now coöperates with the "Day Nursery" at 26, Cartwright-gardens, and the "Nursery School" at 18, Crowndale-road. These institutions are supported by voluntary contributions and voluntary workers, but they appear to be closely associated with the municipal organisation established in connexion with the Notification of Births Act. Dr. Sykes considers it regrettable that Metropolitan borough councils have no power under Section 12 of the Children Act, 1908, which, he claims, would be more valuable in their hands than in those of the County Council and boards of guardians, not so much for the purpose of prosecution, as for enabling sufficient pressure to be brought to bear upon parents whom the health authorities find neglecting to procure necessaries for their children. As in former years, the report deals with a variety of public health questions which are handled on somewhat original lines in St. Pancras, and on the front page, for the benefit of any hostile critics, Dr. Sykes quotes from Captain Cook the following useful sentence: "Preventive measures are always invidious, because when most successful the necessity for them is least apparent."

REPORTS OF SCHOOL MEDICAL OFFICERS.

City and County of Norwich.—The report of Dr. H. C. Pattin brings out several points of considerable interest both from the medical inspector's present point of view and that of the school medical service in general. Many school medical officers will cordially re-echo the remark that routine inspection is apt to pall and welcome the suggestion of a change occasionally to more interesting special work. A table is given showing that out of 394 cases of defect of all kinds needing treatment 189 obtained this from private doctors, four from the school dental officer, and the rest from public institutions in the town. Difficulty has been experienced with regard to treatment, owing to the refusal of one of the town's institutions to accept a subscription from, and allot letters of recommendation to, the education authority on the ground that the inspecting authority ought to provide and pay for treatment, although the same institution receives subscriptions from boards of guardians who have the statutory obligation of providing treatment which education authorities as yet have not got. Pending the settlement of the dispute it is hard that children should be refused treatment which they would otherwise have obtained freely, merely on the ground that they have been inspected in a public school. The absence of a dental institution in the town has led to the founding of a dental clinic opened in November, 1910, which has been successful from the beginning. The cost of this is not to exceed the proceeds of a ½*d.* rate. Ringworm is treated at the municipal offices. A table of importance is that giving the "destination in life" of 830 boy "leavers." Why not girls also? In the better class schools 34 per cent. had no plans, in the mixed class 26 per cent., and in the poorer schools 45 per cent. The grouping of schools is according to the social circumstances of the children. Special centres have been established for mentally subnormal children, and Dr. D. M. Mathieson suggests segregation at both ends of the scale.

City of Sheffield.—Dr. Ralph P. Williams displays and illuminates his statistical returns by some bold diagrams which are of the greatest assistance in making large masses of figures rapidly intelligible. The figures given for "bad" nutrition are from 13,346 children 7·9 per cent., from 6354 senior scholars 9·5 per cent., from 6992 infants 6·5 per cent., and it is stated that the medical officer is guided "by the presence or absence of anæmia and by the condition of the skin and hair, together with the height and weight of the child." It is doubtful, however, whether height can be used safely, and anæmia itself is difficult to estimate precisely. In 126 children hæmic murmurs of the heart were found, these being due to anæmia. A large proportion of these do indicate bad nutrition, and may, perhaps, occur apart from obvious anæmia. It may be mentioned in this connexion that large numbers of free meals are given in Sheffield, last year 198,413 breakfasts being given as well as the meals for children in the special schools. In an appendix of the greatest value attention is called to the career of mental defectives after leaving school, which shows the great necessity there is that legal powers should be obtained for the permanent care of such children. Out of 24 cases only seven were in regular

work and four of these were doing the most unskilled kind of labour. The total average wage of the whole 24 only amounted to 49*s.* per week, the majority being returned as making nothing at all. A large proportion of these cases are subject to attacks of temper more or less severe, and there are vicious, offensively dirty, and hopelessly unimprovable cases amongst them. One girl of 19 was at the time of report six months pregnant and appeared incapable of understanding that there was anything the matter. It is clear that nothing but the offer of facilities—compulsion beyond that supplied by economic stress is not needed—for residence in segregation colonies can be considered to deal adequately with the problem. Meanwhile, raising the school-leaving age so as to tide over the critical 16 year old period would be of great help.

City of Exeter.—This report deals with a total number of children on the register of 7045. Of these no less than 85 per cent. found to have defects were treated, 10 per cent. had left either school or the city, and only 5 per cent. were definitely untreated. The small number dealt with makes this possible. The report calls attention to the value of hygienic advice as for mouth-breathing due to slight enlargement of tonsils and adenoids.

Barry Urban District.—Mr. W. Lloyd Edwards divides children for purposes of nutrition statistics into three classes —above normal, below normal, and bad. No girls are returned as bad, and only 0·06 per cent. boys, while below normal there are only 8·91 boys and 4·48 girls. The figures are derived from 1437 girls (3–14 years) and 1447 boys (3–14). Considerable difficulty has been found with the treatment of defects discovered by medical inspection, and it is reported that with regard to "some classes of defects very little, if anything, is done." The great bulk of cases of dental caries are not treated, and ear discharges, tonsils, and adenoids are largely uncared for despite all the measures taken, even in some ear cases exclusion. These difficulties have led Mr. Lloyd Edwards to prepare and publish as an appendix a "scheme for the establishment of a school clinic" in a form to meet the requirements of the Board of Education. It is proposed to hold the clinic on Wednesday afternoons and on Saturday mornings at the council offices, and here minor treatments will be given. These two sessions will be further utilised for special examinations (truant, mentally defective, and special schools), for cases referred from the school inspection or by teachers and attendance officers, for examination of infectious diseases contacts or convalescents before readmission to school, and for interviews with parents. Ear, nose, and throat cases will be treated by a special arrangement on one afternoon a week at the hospital, vision defects will be treated once a week at a centre fitted up in one of the schools, ringworm will be treated at the hospital in a room to be arranged for the purpose. It may be mentioned that the Barry Hospital is a general hospital built and maintained out of the rates (see 131–133 Public Health Acts, 1875) and that all local medical men who desire to become members are on the staff. This arrangement no doubt simplifies matters and prevents some of the friction which has elsewhere arisen, but the scheme shows in detail just how a school clinic can make use of existing institutions and just where it is necessary to supplement them.

Cardiff County Borough.—Dr. E. Walford, in a note on nutrition, brings forward a very important matter that seriously requires attention. He points out that the medical inspectors report that 10·7 per cent. of male infants are below normal in nutrition and 7·2 per cent. of female infants. For "leavers" the figures are: boys 10·9 per cent. and girls 4·5 per cent. The medical officer points out that it is clear that the difference between the condition of boys and girls must be due to some extent to the different standard of comparison taken by medical inspectors. Comparing townships and counties one with another, this discrepancy is still more obvious, and the need for a definite standard is an urgent matter. Private arrangements for treatment have been made in Cardiff with two ophthalmic surgeons and seven dentists.

Borough of Margate.—The number of children suffering from impaired nutrition amounted to 6·19 per cent., and in view of the good health conditions in Margate this can only be put down to insufficient and improper feeding and bad home conditions, but the lack of a definite standard makes all comparisons very difficult.

Notts County.—Dr. Henry Handford reports that 5·6 per cent. of boys and 5·6 per cent. of girls were found to be below the average in nutrition. A beginning in dental treatment has been made, and some advance is recorded in the number of children who obtain spectacles after being advised to do so. The greatest objection to wearing glasses is in the rural districts. The medical officer reports strongly against the practice of the school medical officer being expected to advise closure of a school, when the attendance has fallen below a certain point owing to the prevalence of infectious illness, merely in order to avoid loss of grant.

County Borough of Huddersfield.—Ringworm in Huddersfield is treated by the local chemists, but the question of a school clinic has been fully discussed and plans are under consideration by the finance committee. The statistics are presented with the addition of a height-weight coefficient for certain age-periods by which it is proposed to measure the value of the social work in Huddersfield in years to come. The authorities have been considering school cleansing. School floors, furniture, windows, and out offices are to be washed and scrubbed seven times a year instead of four as formerly.

County Borough of Southport.—Dr. G. C. Barnes has issued a most painstaking and detailed report analysing the statistics from individual schools. Whooping-cough is a notifiable disease in Southport, and the medical officer remarks that it is just as infectious in Sunday schools as in the day schools, whereas the education authority has no legal control over the former. Every case notified is visited, and every endeavour is made to trace the origin of the disease.

Devon County.—The number of children returned as badly nourished in the administrative county is: boys 0·96 per cent. and girls 0·66 per cent. The teachers in Devonshire weigh and measure the children, do the vision testing, and assist at the examinations. One school nurse has been appointed.

Cambridgeshire County Council.—The medical officer discusses the possibility of starting a rural dental clinic. Official encouragement of the formation of local care committees has also been discussed during the year, but it was decided that lists of the defects notified to parents should be sent to the managers of the schools after each inspection, with a covering letter, seeking to enlist the active sympathies of the managers. Where replies have been received they have been favourable in their terms, but the number of such acknowledgements has been small. In small areas the groups of managers are in such close touch with schools as to be virtually care committees.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 7750 births and 5889 deaths were registered during the week ending Sept. 9th. The revised estimate of population of these towns in the middle of this year is 16,157,797 persons. The annual rate of mortality in these towns, calculated on this revised estimate, which had been 20·9, 21·2, and 20·6 in the three preceding weeks, declined again to 19·0 per 1000 in the week under notice. During the first ten weeks of the current quarter the annual death-rate in these towns averaged 16·6 per 1000, while in London during the same period the mean annual death-rate did not exceed 15·5 per 1000. The recorded annual death-rates in the 77 towns last week ranged from 9·4 in Hastings, 10·6 in Barrow-in-Furness, 11·2 in Wallasey, and 11·8 in Derby and in Halifax to 27·9 in Liverpool and in Burnley, 28·5 in Aston Manor, 28·6 in Stoke-on-Trent, and 33·1 in Sunderland. The 5889 deaths from all causes in the 77 towns last week were 479 fewer than the number recorded in the previous week, and included 2087 which were referred to the principal epidemic diseases, against 2900 and 2617 in the two preceding weeks. Of these 2087 deaths from the principal epidemic diseases no fewer than 1915 resulted from infantile diarrhœa, 58 from whooping-cough, 40 from diphtheria, 29 from measles, 28 from enteric fever, and 17 from scarlet fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases last week was equal to 6·7

per 1000, against 9·4 and 8·4 in the two preceding weeks. The deaths of infants under 2 years of age attributed to diarrhœal diseases in the 77 towns, which had been 2553, 2714, and 2461 in the three preceding weeks, declined again to 1915 last week, and caused the highest annual rates of 10·9 in Stoke-on-Trent, 11·8 in Aston Manor, 13·2 in Grimsby, 13·5 in Merthyr Tydfil, and 13·7 in Burnley. The deaths referred to whooping-cough, which had been 68 and 58 in the two preceding weeks, were again 58 last week, and included 17 in London and its suburban districts, 8 in Liverpool, 5 in Birmingham, 3 in Manchester, and 3 in Hull. The fatal cases of diphtheria numbered 40, and were 5 in excess of the average in the six preceding weeks; 14 deaths were registered in London and its suburban districts, 4 in Liverpool, 3 in Newcastle-on-Tyne, and 3 in Coventry. The deaths attributed to measles, which had been 59, 54, and 34 in the three previous weeks, further declined last week to 29, which was the lowest number recorded in any week of the current year; 11 deaths occurred in London, 4 in Wolverhampton, and 2 each in West Bromwich, Nottingham, Liverpool, and Oldham. The deaths referred to enteric fever, which had been 11, 18, and 21 in the three previous weeks, further rose last week to 28, and was the highest number recorded in any week of the current year; 3 deaths occurred in each of the following towns: London, Portsmouth, Birkenhead, Wigan, and Hull. The 17 fatal cases of scarlet fever were 9 in excess of the number recorded in the previous week, and included 5 in London, 2 in Leyton, and 2 in Leeds. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had declined from 1442 to 1327 in the four preceding weeks, rose to 1349 on Saturday last; 217 new cases of this disease were admitted to these hospitals during the week, against 149, 132, and 168 in the three previous weeks. These hospitals also contained at the end of last week 761 cases of diphtheria, 231 of whooping-cough, 122 of measles, and 89 of enteric fever, but not one of small-pox. The 1510 deaths from all causes in London last week showed a decrease of 19 upon the number returned in the previous week, and included 95 which were referred to diseases of the respiratory system, against 85 and 73 in the two previous weeks. The deaths attributed to different forms of violence in the 77 towns, which had been 152 and 147 in the two preceding weeks, rose to 171 last week, and 322 inquest cases were registered. The causes of 24, or 0·4 per cent., of the deaths registered in the 77 towns during the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified last week in Sheffield, Leeds, Bristol, West Ham, Bradford, Hull, Nottingham, and in 54 other smaller towns. The 24 uncertified causes of death last week included 5 in Liverpool, 4 in Birmingham, and 2 in London.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710 291 persons in the middle of this year, 758 births and 536 deaths were registered during the week ending Sept. 9th. The annual rate of mortality in these towns, which had increased from 14·2 to 17·2 in the three preceding weeks, declined last week to 16·4 per 1000. During the first ten weeks of the current quarter the annual death-rate in these Scotch towns averaged 15·0 per 1000, and was 1·6 below the mean rate during the same period in the 77 large English towns. The annual death-rates in the Scotch towns last week ranged from 11·1 and 12·2 in Paisley and Edinburgh, to 19·4 in Greenock and 20·1 in Aberdeen. The 536 deaths in the eight towns last week were 28 fewer than the number in the previous week, and included 105 which were referred to the principal epidemic diseases, against numbers increasing from 62 to 134 in the five preceding weeks; of these 105 deaths, 78 resulted from diarrhœa, 12 from whooping-cough, 8 from diphtheria, 3 from measles, 2 from scarlet fever, and 2 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 3·2 per 1000, the mean death-rate last week from the same diseases in the 77 large English towns having been 6·7. The deaths attributed to diarrhœa, which had increased from 33 to 113 in the five preceding weeks, declined last week to 78, and included 67 of infants under two years of age; 47 deaths occurred in Glasgow, 13 in Dundee, 6 in Aberdeen, 3 in Greenock, and 3 in Perth. The deaths referred to whooping-cough, which had been 12 and 10 in the two preceding weeks, were 12 last week, and included 4 in Glasgow and 2 each in Edinburgh, Dundee, and Aberdeen. The fatal cases of diphtheria, which had been 5 in each of the two preceding weeks, rose to eight last week, of which 3 were registered in Glasgow, 2 in Dundee, and 2 in Leith. The deaths from measles, which had declined from 11 to 4 in the five preceding weeks, further declined last week to 3, and included 2 in Glasgow and 1 in Greenock. The 2 fatal cases of scarlet fever were recorded in Aberdeen, and those of enteric fever in Glasgow and Aberdeen respectively. The deaths referred to diseases of the respiratory system in the eight towns, which had been 29, 41, and 24 in the three previous weeks, rose to 53 last week, and were 11 in excess of the number in the corresponding week of last year. Of the 536 deaths from all causes in the eight towns last week, 167, or 31 per cent., were recorded in public institutions, and 21 deaths were attributed to different forms of violence. The causes of 20, or 3·7 per cent., of the deaths in the eight towns last week were not certified; in the 77 English towns the proportion of uncertified causes of death during the week did not exceed 0·4 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 598 births and 487 deaths were registered during the week ending Sept. 9th. The annual rate of mortality in these towns, which had been 19·4, 19·3, and 21·0 per 1000 in the three preceding weeks, further rose to 22·1 per 1000 in the week under notice. During the first ten weeks of the current quarter the annual death-rate in these towns averaged 18·0 per 1000; in the 77 English towns during the same period the mean annual death-rate was equal to 16·6, whilst in the eight Scotch towns it did not exceed 15·0. The annual death-rate last week was equal to 27·1 in Dublin (against 17·4 in London), 19·7 in Belfast, 25·2 in Cork, 16·6 in Londonderry, 17·7 in Limerick, and 26·6 in Waterford; whilst in the 16 smallest of these towns the mean annual death-rate did not exceed 16·0 per 1000. The 487 deaths from all causes in the 22 Irish towns were 25 in excess of the number returned in the previous week, and included 130 which were referred to the principal epidemic diseases, against 133 and 153 in the two preceding weeks; of these 130 deaths, 117 resulted from diarrhœal diseases, 6 from whooping-cough, 3 from diphtheria, 2 from enteric fever, 2 from scarlet fever, but not one from measles or from small-pox. These 130 deaths from the principal epidemic diseases were equal to an annual death-rate of 5·9 per 1000. The mean rate from the same diseases in the 77 English towns was equal to 6·7, while in the eight Scotch towns it did not exceed 3·2 per 1000. The deaths attributed to diarrhœal diseases, which had increased from 104 to 141 in the three preceding weeks, declined to 117 last week, and included 105 of infants under two years of age. Forty-nine deaths occurred in Dublin, 44 in Belfast, and 8 in Cork. The deaths from whooping-cough, which had been 8 and 7 in the two preceding weeks, were 6 last week, and included 4 in Dublin, 1 in Belfast, and 1 in Cork. The 3 fatal cases of diphtheria, of which 2 were registered in Dublin, were equal to the average in the three preceding weeks. The 2 deaths from enteric fever were recorded in Belfast, and those from scarlet fever in Dublin and Belfast respectively. The deaths referred to diseases of the respiratory system in the 22 town districts, which had been 30 and 31 in the two preceding weeks, rose to 44 last week. Of the 487 deaths from all causes in the 22 towns last week, 137, or 28 per cent., occurred in public institutions, and 8 deaths were attributed to different forms of violence. The causes of 8, or 1·6 per cent., of the deaths last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes of death during the week under notice did not exceed 0·4 per cent. in the 77 large English towns, and was equal to 3·7 per cent. in the eight Scotch towns.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Order in Council of April 1st, 1881: Fleet-Surgeon John Lloyd Thomas has been placed on the retired list with permission to assume the rank of Deputy Surgeon-General (dated Sept. 3rd, 1911). The following appointments have been notified:—Fleet-Surgeons: J. D. Hughes, J. McElwee, G. T. Bishop, and S. T. Reid to the *President*, additional, for Civil Hospital Course; E. R. D. Fasken to the *Devonshire;* A. X. Lavertine to the *Terrible;* E. A. Shaw to the *Antrim;* and B. F. Parish to the *Actæon*. Staff-Surgeons: J. H. L. Page to Devonport Dockyard; G. C. C. Ross to the *Vivid*, additional, for disposal; W. E. Mathew to the *Forth;* E. Folliott, A. J. Laurie, J. Verdon, L. M. Morris, R. H. Atkins, and A. W. Iredell, to the *President*, additional, for Civil Hospital Course; and E. D. J. O'Malley to the *Amethyst*. Surgeons: W. R. Harrison, R. F. MacMahon, G. H. S. Milln, A. D. C. Cummins, G. Moir, and J. McCutcheon, all to the *President*, for Civil Hospital Course; A. R. Davidson to the *Indefatigable;* R. H. St. B. E. Hughes to the *New Zealand*, additional, for Portsmouth Subdivision of Home Fleet; J. D. Keir to the *Venerable;* and G. W. M. Custance to the *Pembroke*, additional, for disposal.

ROYAL ARMY MEDICAL CORPS.

Captain Horace H. Kiddle is placed temporarily on the Half-pay List on account of ill-health (dated Sept. 2nd, 1911).

Colonel L. E. Anderson, principal medical officer of the Allahabad Brigade, has taken up duty at Bareilly as Principal Medical Officer of the Bareilly, Gharwal, and Dehra Dun Brigades. Lieutenant-Colonel J. C. Morgan, on promotion, has vacated the appointment of specialist sanitary officer in the Dublin District. Major J. Ritchie, from Multan, has been appointed to command the Station Hospital at Dalhousie. Major F. J. W. Porter, D.S.O., from the Military Hospital at Cosham, has taken up duty as Medical Officer in Charge at Lodmoor Camp. Major D. J. Collins has been selected for the appointment as Specialist Sanitary Officer at Dublin. Captain H. B. Connell has been ordered to Ireland for temporary duty, and on arrival will be posted to the Dublin District. Captain P. J. Hanafin has been appointed Specialist in Ophthalmology at Dublin in succession to Major D. J. Collins. Captain H. H. A. Emerson, at present doing duty at the Military Hospital, Clonmel, has been selected for the appointment of Adjutant of the Royal Army Medical School of Instruction, North Midland Division at Derby, with effect from Nov. 1st next. Captain J. H. Brunskill, Dublin, has been selected for appointment as Clinical Pathologist at the Curragh Camp. Sanction has been given by the War Office for an exchange of position on the Foreign Service Roster between Captain C. S. Smith and Captain R. N. Woodley serving at Mullingar and Bulford Camp, Salisbury Plain, respectively. Captain C. S. Smith will accordingly be required to embark for India for duty with the Northern Army about Jan. 27th next. Captain W. Bennett has been transferred from Naini Tal to the Station Hospital at Calcutta. Captain F. E. Rowan-Robinson from Colchester has taken up duty at the Military Hospital, Norwich. Captain P. Davidson, D.S.O., on completion of duty at the Royal Army Medical College, London, has been posted to the Aldershot Command for duty. Captain P. G. Hyde from Dublin has been placed in medical charge of Rathmore Camp. Captain J. W. S. Seccombe from Jhansi has been appointed to the Station Hospital at Nasirabad.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel H. C. L. Arnim has been granted leave of absence home from India for a period of two years. The services of Lieutenant-Colonel B. B. Grayfoot have been placed at the disposal of the Government of India by His Excellency the Commander-in-Chief. Major W. S. Willmore, on completion of special duty at the Central Research Institute at Kasauli, has been appointed Civil Surgeon to the Mirzapur district. Major T. S. Novis has been appointed Presidency Surgeon, Professor of Anatomy and Curator of the Museums at the Grant Medical College, Bombay. His Excellency the Governor of Bombay in Council has appointed Major R. W. Anthony on return from leave to be Civil Surgeon of Belgaum. Captain R. B. Nicholson has been appointed to the Medical Charge of the 36th Horse. Captain J. Husband has been appointed to the Medical Charge of the 30th Mountain Battery and Frontier Garrison Artillery. The services of Captain R. M. Barron have been replaced at the disposal of the Government of India by His Excellency the Commander-in-Chief. Captain G. A. Jolly, officiating civil surgeon, Mainpuri, has been selected to hold visiting medical charge of the Etah District. Captain M. S. Irani has been appointed Civil Surgeon of Bijapur District.

TERRITORIAL FORCE.

Royal Army Medical Corps.

Attached to Units other than Medical Units.—Lieutenant John Leach to be Captain (dated May 18th, 1911).

Major William C. Beatley resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated Sept. 9th, 1911).

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

In the September issue of this journal Captain W. R. O'Farrell, R.A.M.C., and Dr. A. Balfour, director of the Wellcome Tropical Research Laboratories at the Gordon College, Khartoum, discuss Granule Shedding in Treponema Pallidum and Associated Spirochætæ. Lieutenant H. Stott, I.M.S., makes a contribution to the study of the Ætiology of Beri-beri, and Lieutenant W. E. Marshall, R.A.M.C., describes Experimental Kala-azar in the Grey Monkey of the Sudan. Some Observations on Body Temperature, made by officers specialising in physical training during their course at the Royal Army Medical College, are chronicled by Captain P. Davidson, D.S.O., R.A.M.C., and Captain N. Dunbar Walker, R.A.M.C. An interesting contribution is one from the pen of Major W. S. Harrison, R.A.M.C., who records a case of Chronic Bacillary Dysentery due to a hitherto Undescribed Bacillus. Bacillary dysentery, as the author points out, has been attributed at various times to many other members of the colon group besides the Shiga, Kruse and Flexner bacilli, but Major Harrison has been unable to trace any record of a case caused by a bacillus similar to the one which he describes. The patient rapidly improved after the administration of a vaccine made from the bacillus. Within the last few years the value of iodine as a disinfectant for the skin has been much discussed, and among the advocates of its use in this connexion is Colonel N. Autelo of the Medical Corps of the Argentine Army. In "A New First-aid Packet" he discusses the purposes of and need for a first-aid dressing on the battle-field, and describes his own dressing "packet," which contains a phial of tincture of iodine. The article includes a table giving the principal specifications of the first-aid packet as used at present in the organised armies of the world.

ACCELERATED PROMOTION IN THE ROYAL ARMY MEDICAL CORPS.

It has been decided that the accelerated promotion granted to captains of the Royal Army Medical Corps who pass their qualifying examination for promotion to major in the second class (six months' acceleration) and in the third class (three months' acceleration) will not be applicable to officers promoted to the rank of captain after Dec. 31st, 1908. This means, for all practical purposes, that accelerated promotion in the Royal Army Medical Corps becomes nearly impossible, as under 1 per cent. of officers ever qualify in the first class (12 months' acceleration), and now that acceleration in the classes in which men hope to qualify has been abolished, several hundred officers who came into the Army Medical Service hoping to obtain accelerated promotion if successful in their promotion examination have their hopes dashed to the ground. The Royal Warrant was carefully remodelled by Sir Alfred Keogh, K.C.B., during his tenure of office as Director-General of the Army Medical Service, and its present alteration appears to require some explanation from the members of the Advisory Board or the present Director-General.

ON Monday next, Sept. 18th, at 3 o'clock P.M., a series of living pictures illustrating life on the Oxo Cattle Ranches will be exhibited at the Model Oxo Factory, 43 to 51, Park-street, Southwark Bridge.

Correspondence.

"Audi alteram partem."

"COMFORTER" OTITIS MEDIA.

To the Editor of THE LANCET.

SIR,—The suggested relationship between ear disease and the use of the "dummy teat," outlined by Mr. W. H. Bowen in an article under the above heading in THE LANCET of Sept. 9th, p. 758, adds yet another charge to the long list of criminal indictments recorded against this instrument of torture. That the comforter should be tolerated in this age of hygiene is undoubtedly largely due to the example, the apathy, and the conduct of the medical profession. One distinguished children's specialist in London has, to my knowledge, advocated its use in his lectures to health workers. Further, I regret to say that I still occasionally see the Wimpole-street baby with a dummy in its mouth creating prospective work for the Harley-street throat specialist, and I have frequently heard my learned brethren argue that unrestrained crying is fraught with more serious consequences than sucking indiarubber teats. If gold rusts in this way what are we to expect of iron?

Although, I imagine, there are few who have taken a more active part in the crusade against comforters than I have myself, none the less I do not believe their chief offence is the introduction of septic matter into the mouth. I regard as more injurious the habit of sucking which it induces, for this soon becomes an undoubted "tic" and has subsequent consequences which are not easy to measure. Further, the constant pressure of the teat against the roof of the mouth and the associated muscular actions must, on purely mechanical grounds, tend to accentuate and aggravate the highness and narrowness of the palate, which is one of the characteristic tendencies of recent human evolution.

With Mr. Bowen I certainly believe that the use of the comforter contributes to the highly complex pathogenesis of adenoids and otitis media, but not only in the manner that he suggests. Every infant in the East-End of London has its comforter just as surely—indeed, more surely—than it has a tight binder round its abdomen, so that, in spite of Mr. Bowen's belief that a deduction with respect to the correlation between comforters and otitis media can be drawn from East-End experiences, I beg altogether to differ from him. All East-End infants have comforters, and nearly all have adenoids, but this is no proof that there is any closer correlation. For the last six and a half years I have kept a systematic record of the "tonsil and adenoids" history of every infant brought to my "infant consultations" in Marylebone. These records include the cases of nearly 1000 infants who have been kept under observation, in some cases for nearly two years, and in most instances for many months. My experiences derived from this source of information are that adenoids and enlarged tonsils, or at least their commencements, are exceedingly common during the first year of life, and that they are often sufficiently obstructive to require surgical removal. Both Mr. T. Jefferson Faulder and Mr. Rupert Farrant at the St. Marylebone General Dispensary, and Mr. W. G. Howarth at the Queen's Hospital for Children, have operated at my request on quite a number of infants under one year of age, and occasionally under six months. Only cases have been chosen for operation which have proved intractable to the routine methods of medical treatment, but the results in all cases have greatly encouraged me to have recourse to early operative interference. On the whole, I have found adenoids, enlarged tonsils and otitis media quite as common among Marylebone infants who, relatively speaking, seldom have comforters, as among Hackney infants who possess them without exception.

The typical adenoids, tonsils, and otitis history, of which I have over a hundred, is as follows. At about the third month of life the infant has a slight pharyngeal cough and running of the nose (an ordinary cold due to defective hygienic conditions and respiratory noxæ). The infection then probably extends to the Eustachian tube, and a small chain of enlarged lymphatic glands begins to develop from the mastoid process downwards. These glands continue to increase in size *pari passu* with the growth of the lymphatic hyperplasia of the naso-pharynx. After a time, usually from three to six months, evidence of distension of the middle ear begins to show itself by pain, crying, restlessness, rolling of the head (meningismus), and bulging of the membrane. With rupture of the membrane and otorrhœa the symptoms rapidly subside. Incision of the membrane greatly expedites matters, but the operation is troublesome to perform without an anæsthetic.

That naso-pharyngeal sepsis has its origin in a large number of cases at, or even before, the third month is quite indisputable, and this before mouth-breathing has become habitual or even occasional. Accursed instrument as the comforter undoubtedly is, this much must at least be said for it: it tends to promote nasal breathing by keeping the mouth closed in a perennial act of sucking.

I am, Sir, yours faithfully,

London, W., Sept. 8th, 1911. ERIC PRITCHARD.

THE RADIO-ACTIVITY OF SEA-WATER.

To the Editor of THE LANCET.

SIR,—I venture to supply data pertinent to the query contained in the letter of Dr. F. Hernaman-Johnson appearing in THE LANCET of the 9th inst.

That sea-water contains radio-active substances is undoubted owing to the measurements of Eve, Joly, and Knoche. These observers have made quantitative determinations of the amount of radium contained in a litre of sea-water. The quantity is exceedingly small, as is evidenced by the following numbers. Eve obtained water from the North Atlantic, and found a mean value of $0\ 9 \times 10^{-12}$ grm. of radium per litre—i.e., about one billionth of a gramme per litre. Joly has made determinations of the radium content of ocean water from various parts of the world, from which it is evident that widely different values are to be anticipated. The mean of a large number of observations by Joly is 16×10^{-12} grm. of radium per litre. It may be noted that observations of the radium content of river-water, those of the St. Lawrence by Eve and of the Nile by Joly, gave values about one-quarter of the values obtained by them for sea-water. Knoche from 12 observations of Atlantic water obtained a mean value of 17×10^{-12} grm. of radium per litre. Knoche points out that this quantity is about one-twentieth of that in a *weak* radio-active spring.

It is not within my province to offer an opinion as to the therapeutic value of radium, but one or two statements contained in the letter in question call for comment. Dr. Hernaman-Johnson bases his arguments for the therapeutic value of salt water being due to its radio-activity upon the assertion that salt water is not efficacious after it has been kept for three weeks. If sea-water owed its radio-activity only to the radium emanation dissolved in it, it is true that, on keeping, its activity would decrease to a few per cent. of its original activity in this time. But this is not the case. The measurements which I have cited were made upon samples of sea-water which in some cases were several months old, and proved the presence not only of the emanation but of the parent substance—radium itself. This being so it is clear that the amount of emanation in a sample of sea-water remains constant, for its spontaneous disappearance is balanced by its production from the parent substance.

As to the origin of this radio-activity, upon which Dr. Hernaman-Johnson touches, one cannot do better than quote the opinion of Professor Joly[1]: "Oceanic radio-activity is, most probably, in part referable to the denudation of rocks and the transport of the dissolved and suspended radio-active materials to the ocean. The considerable amounts of radium contained in deep-sea sediments, even from the most central parts of the ocean, suggests that much of the uranium reaches the sea in solution or in very fine suspension, and, in part, ultimately finds a resting-place among the oozes everywhere slowly collecting."

I am, Sir, yours faithfully,

SIDNEY RUSS, D.Sc. Lond.,
Beit Medical Research Fellow.
Cancer Research Laboratories, Middlesex Hospital, Sept. 11th, 1911.

A QUESTION IN EUGENICS.

To the Editor of THE LANCET.

SIR,—Your correspondent of Sept. 9th complains that the main issue of this discussion has been obscured by emotionalism. In whetting his wits on the sermon he loses sight of the text. The original query [1] had reference to "the legal and moral aspects of the case," and consequently every reply which ignores these aspects is irrelevant. If all expression of opinion upon ethical questions, though couched in sober phrase, be accounted "emotional," no doubt I for one must plead guilty, though even to please your correspondent I regret that it is beyond my powers to answer one question by replying to another. Possibly, in his opinion, all ethical considerations whatsoever are tantamount to rubbish, but if not I will endeavour to satisfy him not only by setting my view of the issue "in the dry light of intelligence," but by the use of the baldest Saxon.

The moral aspects of this case involve a few "emotional" factors, such as humanity, justice, and parental and professional ethics, which, since they determine, first, opinion, and, secondly, conduct, are not practically negligible. Let us bracket the first two together and deal with them seriatim.

1. Since the degenerate individual is an actuality and posterity a potentiality, is it humane and just upon the part of society to inflict injury upon anything *in esse* for the sake of otherwise obtainable benefits to something *in posse?* To be sure, your correspondent appears to argue that by injuring the individual we are in reality doing him a kindness in freeing him from a burden of anxiety and expense which he may possibly never contract, or may be prevented from contracting, without the necessity of submitting to an objectionable form of mutilation. I venture to submit that the patient himself would not agree with this sophism, and would find his dissent endorsed both by the laws of the land and by the consensus of public opinion.

2. If it be morally desirable that a father should procure the sterilisation of his epileptic child, surely there is something wrong with our present conceptions of the parental relation. If the true object of parental affection be the race rather than the individual, it would seem "in the dry light of intelligence" that a father's proper course with regard to the weaklings of his brood would be to treat them like kittens and put them in the bucket.

3. As to the professional aspects of the case I have already stated my opinion that a surgeon's duty is to his patient, and that the only legitimate use of the knife is to remove disease or to alleviate personal suffering; and the "light of intelligence," however "dry," only serves to bring this duty into greater prominence. Dispassionate ratiocination no more implies callousness than a cool head implies a cold heart

If I do not misinterpret his somewhat loose phraseology, your correspondent seems willing to allow to the unfit the option either of retiring to a colony for degenerates or of being sterilised and free. So far so good; but the alternative—if, indeed, it be seriously proposed—is in no way practicable. Can a child or a lunatic comprehend the terms of the option? There is also this further objection—namely, that unless the unfitness of the degenerate who has preferred sterilisation be of a minor order, in which case it would become a nice question whether there were any real need to sterilise him at all, he might possibly find himself both sterilised and secluded. It must be remembered that sterilisation, far from being a panacea for degeneracy, is a positive aggravation of it, and that the sterilised degenerate is thereby rendered even less fit than before to assume the control over his own actions. All sexual disabilities, whether congenital or acquired, have an injurious effect upon the mental organisation; and though one such condition may be less injurious than another, it is none the less true that they are all of them harmful. This statement holds both of vasectomy and of cryptorchidism. It is needless to inform anybody, save those who read only to misread, that no party to the present correspondence has sought to establish any further analogy between these two conditions.

This being a free country, I suppose that it is within the option of those void of understanding to mutilate themselves, by vasectomy or otherwise, in order to avoid this or that responsibility which nature has entailed upon them, but such practices are indicative of mental unsoundness, and are beacons to warn, not signals to direct. As there are more ways of killing a dog besides hanging him, so there are more ways of dealing with a degenerate besides mutilating him. The "dry light of intelligence" need not blind us to the existence of alternatives. That were more characteristic of the light of a dry intelligence. Let us beware lest we mistake the one for the other.

I learn with satisfaction that the sterilisation of degenerates is not yet legalised in Switzerland, and that Indiana still possesses the monopoly of this egregious enactment.

I am, Sir, yours faithfully,

BRYAN CHARLES WALLER, M.D. Edin., F.R.C.S.

Kirkby Lonsdale, Sept. 11th, 1911.

[1] THE LANCET, July 29th, 1911, p. 328.

THE CURIOUS HISTORY OF A SWALLOWED PIN.

To the Editor of THE LANCET.

SIR,—The interesting communications from Dr. W. Balgarnie and Dr. I. D. Chepmell, which have lately appeared in THE LANCET under the above head, remind me of two experiences of my own where the errant body was a needle.

Sixty years ago the late Dr. Lionel Beale was house physician at the King's College Hospital, and I had the privilege of acting as clinical clerk for the late Dr. Bentley Todd, under whose care a woman was admitted suffering from obscure gastric symptoms. Her case required and received constant and careful examination. One morning Dr. Beale discovered a small painful spot in the epigastrium, and a feeling suggestive of the presence of a foreign body. This was cut down upon and a small needle withdrawn without any difficulty. A day or two after another such appeared which I removed in a similar manner. During the ensuing four or five weeks we extracted between us 43 needles and three pins from the epigastric region.

At first the patient denied all knowledge, but when the collection increased she stated she remembered that years ago she had swallowed a packet of needles. On finding the pins, which had all lost their heads, we carefully examined the needles and found all imperfect, a few having lost their points, but most of them had broken eyes. On drawing the patient's attention to this fact and explaining to her that it was not usual to sell damaged needles, to say nothing of pins in a packet, she made the following statement. She had for years earned her living by fine needlework, and had been in the habit, on breaking a needle, of thrusting it into her stomach instead of throwing it away. I think from her generally neurotic condition this explanation was probably the true one. I believe the case terminated fatally soon after I lost sight of her. The collection was, I fancy, sent by Dr. Beale, with a note of the case, to the Museum of the Royal College of Surgeons of England.

Another case occurred some years after in my private practice as follows. Sent for one morning to see a child suddenly attacked the day before with acute pain in the knee, I found a fine healthy girl (3 to 4 years old), stated never to have had an ailment till yesterday, when she felt acute pain in the right knee but which soon passed off. I found the joint apparently normal, painless, with motion unimpaired and sound; during manipulation on pressing my finger over the internal condyle the child screamed with pain, and on more careful examination I fancied I detected a foreign body. I cut down and exposed a sharp point, seized it with forceps, and with some difficulty withdrew a large perfect carpet needle, which appeared to have transfixed the two condyles of the femur. The needle was about 2 inches in length, very strong and very firmly held by the tissues, and withdrawn with some difficulty. As a precaution I applied a splint and kept the child in bed for a day or two, but she never suffered the least inconvenience and was perfectly well at once. The pain was evidently due to the needle having shifted its position. The mother and nurse were both greatly exercised and could throw no light on the matter. There had been no upholstering in the house, for which kind of work such needles are chiefly used. There was no scar on the outside of the joint indicating the point of entry of the

needle, and until the day before my visit no suspicion of anything wrong. This is one of many experiences that in the course of a long practice have passed my understanding.

I am, Sir, yours faithfully,

EDW. LIDDON, M.D. Edin., J.P. (Som.).

Taunton, Sept. 7th, 1911.

THE TREATMENT OF TORTICOLLIS.

To the Editor of THE LANCET.

SIR,—I was interested to read in your issue of this week the article by Mr. Paul B. Roth on this subject and pleased at his protest against the various forms of retention apparatus so commonly recommended and still frequently employed. I would go even further and say that the exercises and manipulations which he employs are equally unnecessary. During the last few years I have operated on rather a large number of these cases and have gradually discarded almost all forms of subsequent treatment, whether by apparatus, exercises, or manipulations, and have been very pleased with the results. After division of the affected muscle I have the child kept lying flat on the back with no pillow for between two and three weeks, allowing free movement of the head, for I think the one thing that makes for a recurrence is allowing the child to sit up.

Under any circumstances relapses after operation for torticollis seem to be very rare, and I cannot call to mind a single case that has been bad enough to necessitate a second operation; in fact, the very good prognosis after operation is one of the several rather curious features of the affection. I entered somewhat fully into the subject in a paper in the Archives of the Middlesex Hospital, July, 1910, and Mr. Roth would see there how fully I am in accord with his own views as to the use of apparatus subsequent to the operation.

I am, Sir, yours faithfully,

Queen Anne-street, W., Sept. 9th, 1911. THOS. H. KELLOCK.

SALVARSAN ("606") AND MERCURY IN THE TREATMENT OF SYPHILIS.

To the Editor of THE LANCET.

SIR,—May I trespass on your space to correct an inaccurate statement attributed to me in THE LANCET of August 12th, p. 474, by Mr. W.d'Este Emery, who says, "In THE LANCET of July 29th Major H. C. French states that it is impossible to carry out the Wassermann reaction *quantitatively* by any of the ordinarily suggested *modifications*." If Mr. d'Este Emery had read my article more carefully he would have observed that I quoted the *opinion* of Mr. Boas, an acknowledged authority on Wassermann's work.

I wrote that "Mr. Boas recently lays great stress upon the importance of carrying out all Wassermann's reactions in a *quantitative* manner—a method which is impossible in the case of all the ordinary suggested *modifications*. Mr. Boas obtained much better results and stated that the Wassermann reaction has not, and *will not, obviate the necessity for clinical observation* in syphilis."

Mr. H. W. Bayly, in THE LANCET of August 12th, p. 473, endorses my statement. He writes: "I am entirely in accord with Major French's quotation of Mr. Boas's opinion as to the superiority of Wassermann's original technique and the importance of *quantitative* estimations."

I am, Sir, yours faithfully,

Sept. 5th, 1911. H. C. FRENCH, Major, R.A.M.C.

THE PATHOLOGY OF PAPILLŒDEMA.

To the Editor of THE LANCET.

SIR,—In the notice in THE LANCET of Sept. 2nd, p. 700, on Mr. Leslie J. Paton and Dr. Gordon M. Holmes's paper on the Pathology of Papillœdema credit is given to these authors for originality in the hypotheses advanced for explaining the origin of this condition. I am, therefore, compelled to state that in this matter they have, no doubt unintentionally, omitted to acknowledge my work on this subject published in my book, "Glaucoma, an Inquiry into the Physiology and Pathology of the Intra-ocular Pressure," to which they do not refer except in the last three lines of their paper.

I am, Sir, yours faithfully,

Nottingham, Sept. 4th, 1911. THOMSON HENDERSON.

SANITATION AND THE KORAN.

To the Editor of THE LANCET.

SIR,—I note that, in the issue of THE LANCET of August 19th, p. 526, in your report of the discussion of Professor Simpson's paper on The Sanitation of Villages and Small Towns in the Tropics, with Special Reference to Efficacy and Cheapness," I am reported to have said, touching the utilising of the religion of the natives in advancing the standard of public health among them, that "the Khoran, unfortunately, gave no help whatever in this direction." This is the very reverse of what I said. What I did say was that there were very few principles of elementary sanitation for which support could not be found either in the Koran itself or in the teaching of the Muhammadan doctors.

I am, Sir, yours faithfully,

M. CAMERON BLAIR.

Royal Societies Club, St. James's-street, S.W., Sept. 6th, 1911.

THE CHOLERA EPIDEMIC.

(FROM THE BRITISH DELEGATE TO THE CONSTANTINOPLE BOARD OF HEALTH.)

SINCE the date of my last letter on this subject[1] there has been a considerable extension of the cholera epidemic. It is now prevalent in many parts of Asia Minor and Mesopotamia, in Constantinople itself, in the Macedonian vilayets, and it has quite recently appeared in Mecca. It has slightly increased in Russia; it is still epidemic in Italy; and the infection exists, though scarcely in epidemic form, in certain places in France, in Austria and Hungary, in Montenegro, and in Persia.

Cholera in Russia.

The following are the latest returns of the epidemic in Russia:—

Week ending July 16th (29th)			35	cases,	12	deaths.
,, ,, ,, 23rd (Aug. 5th) ...			52	,,	22	,,
,, ,, ,, 30th (,, 12th) ...			71	,,	37	,,
,, ,, Aug. 6th (19th)			134	,,	57	,,
,, ,, ,, 13th (26th)			174	,,	79	,,

It will be seen that the figures are still rising. In the first week of the table the disease was confined to the governments of Samara, Saratof, Stavropol, and Astrakhan, and the town of Odessa. To these were successively added the governments of Simbirsk, Tambof, Voronezh, Ekaterinoslav, Kostroma, Moscow, and Yaroslavl, the territories of Kuban and Daghestan, and the towns of Baku, Novorossiisk, and Rostof-on-Don.

Cholera in Constantinople.

The latest weekly returns have been as follows:—

August 1st to 7th			181	cases,	100	deaths.
,, 8th ,, 14th			263	,,	139	,,
,, 15th ,, 21st			394	,,	213	,,
,, 22nd ,, 28th			200	,,	137	,,
,, 29th ,, Sept. 4th			324	,,	155	,,

The infection is widely spread through many parts of this city and its suburbs. Much alarm has been created by the occurrence of a large number of cases at Buyukderé, a village near the northern end of the Bosphorus, where the Russian Embassy and some legations pass the summer, and which is a favourite resort in the hot months for many of the inhabitants of the capital. Another "foyer" of the disease formed at Haskeui, a low-lying quarter near the tip of the Golden Horn largely inhabited by Jews. The above figures apply only to the civilian population of Constantinople; they would have to be considerably increased were the cases occurring among the troops also included. I refer below to this important question of the spread of cholera by troops returning from Albania.

[1] THE LANCET, August 19th, p. 538.

Cholera in Asia Minor and Mesopotamia.

The disease is on the increase in Smyrna, as shown by the following figures:—

Week ending July 30th	.....	27	cases,	18	deaths.
,, ,, August 6th	.....	18	,,	11	,,
,, ,, ,, 13th	.....	52	,,	37	,,
,, ,, ,, 20th	.....	122	,,	80	,,
,, ,, ,, 27th	.....	117	,,	63	,,
,, ,, Sept. 3rd	.....	188	,,	86	,,

This increase of the disease in Smyrna is attributed to the contamination of certain sources of water-supply. These sources have been ordered to be closed and others substituted for them, and it will be of interest to observe if this measure is followed by a marked subsidence of the epidemic. At Zunguldak, on the Black Sea, the disease still lingers among the coal-miners. Elsewhere in Asia Minor cholera is more or less prevalent at several places in the vilayets of Angora, of Sivas, of Konia, and of Broussa. The following are the latest returns from the Bagdad vilayet:—

From July 28th to August 4th	.....	27	cases,	15	deaths.
,, August 5th ,, ,, 11th	.....	7	,,	10	,,
,, ,, 12th ,, ,, 18th	.....	7	,,	4	,,
,, ,, 19th ,, ,, 26th	.....	10	,,	7	,,
,, ,, 27th ,, Sept. 2nd	.....	47	,,	25	,,

The majority of these cases have occurred at Amara, on the Tigris. Only a few have been seen in Bagdad itself, and still fewer at Kerbela. The disease still prevails at Basra, though it is decreasing, as shown by the following figures:—

From July 30th to August 3rd	...	31	cases,	24	deaths.
,, August 4th ,, ,, 9th	...	25	,,	18	,,
,, ,, 10th ,, ,, 15th	...	30	,,	20	,,
,, ,, 16th ,, ,, 25th	...	14	,,	9	,,
,, ,, 26th ,, Sept. 2nd	...	9	,,	8	,,

From Consular reports it may be gathered that the infection was apparently brought to Basra from Amara and Ezra's Tomb (Ozeir), on the Tigris, by labourers who come into Basra at this season with lighters of grain.

Cholera in Persia.

The outbreak of cholera at Mohammerah, mentioned in my last letter, has since extended considerably. At Mohammerah itself the following figures have been reported:—

Week ending July 29th	.....	2	cases,	2	deaths.
,, ,, August 5th	.....	9	,,	8	,,
,, ,, ,, 12th	.....	91	,,	76	,,
,, ,, ,, 19th	.....	53	,,	51	,,
,, ,, ,, 26th	.....	40	,,	33	,,

From Mohammerah the disease spread to Ahwaz, some distance up the Karun river. In the week ending August 12th 12 cases and 7 deaths were seen here; in the two following weeks there were respectively 47 cases with 51 deaths, and 49 cases with 45 deaths. The disease was also reported to have appeared at Abadan.

Cholera in Syria and Palestine.

A single case of the disease was recently reported from Damascus. Several imported cases have occurred on pilgrim ships in quarantine at the lazaret of Beirut, but none in the town. Single cases (apparently imported) have also been seen at Jaffa and Caiffa.

Cholera at Mecca.

Of still graver import than any of the outbreaks as yet recognised is the appearance, now reported, of the disease among the pilgrims at Mecca. It may be noted that the month of fasting—Ramazan—began on August 25th of this year. During the month good Moslems allow nothing to pass their lips between sunrise and sunset, and many of them make up for this fast by much feasting at night. The conditions thus brought about have always proved favourable to the prevalence of cholera; and this must especially be the case among pilgrims, doubly so among pilgrims in the holy town of Mecca itself, and trebly so in the droughty heats of late summer and early autumn. A severe epidemic of the disease in this year's Haj must therefore, unfortunately, be anticipated. An added danger lies in the fact that this year, it appears, the first day of Kurban Bairam will fall on a Friday; the pilgrimage will therefore be a Haj-i-Akbar, and may be expected to be attended by exceptionally large numbers of pilgrims. There are already signs that this will be the case.

The first intimation of the appearance of cholera at Mecca was contained in a telegram dated Sept. 1st, which stated that three Javanese pilgrims from Singapore, inhabiting the same house, had simultaneously fallen ill in the night with all the symptoms of cholera. The next day's telegram reported that 11 more suspected cases, with 2 deaths, had occurred since the previous night, and that 15 others had been recognised after death. These figures alone speak of a rapid extension of the disease among a particularly susceptible population.

Cholera in the Yemen.

Cholera appears to have been more or less prevalent in Hodeidah and other places in the Yemen (such as Loheia, Zeidieh, &c.) through the greater part of August. But at Hodeidah the outbreak is said to have come to an end on the 25th of the month.

Cholera in the Macedonian Vilayets and among Returning Troops.

As mentioned in my last letter, cholera has been prevalent among the troops recently engaged in the military operations in Albania. Cases and deaths in considerable, but not in very large, numbers have been reported from Ipek, from Scutari, from Monastyr, from St. Giovanni di Medua, and from Valona. In none of these places can the outbreak be described as severe; but, unfortunately, the troops returning thence to other parts of the country have been instrumental in spreading the infection far and wide. Many infected groups of soldiers arrived at Salonica with the disease amongst them. Some, but not all, were put into isolation camps in or near Salonica; but most of the infected groups appear to have been at once put on board transports and sent to their destination. The result has been that a series of deeply infected transports have recently arrived at Smyrna, the Dardanelles, and elsewhere. On some as many as 50, 100, 150, or even more, cases of cholera occurred during the journey of 24 to 30 hours, and large numbers of deaths were reported on their arrival. The Turkish lazarets have been filled to overflowing with these troops, and recently it has been found necessary, instead of sending them to the lazarets (which were never intended for troops), to land them on the shores of the Bosphorus, or elsewhere, and place them under tents in improvised quarantine stations. This movement of infected regiments from Salonica and elsewhere is, unfortunately, and in spite of energetic representations, still continuing. In spite of equally energetic representations it was fully intended to hold the autumn manœuvres this year in the Macedonian vilayets; but, fortunately, commonsense has at last prevailed, and it was officially announced on Sept. 5th that, owing to the cholera epidemic, these manœuvres had been countermanded.

Cholera in Montenegro.

On August 29th a telegram from Podgoritza reported that a few cases of cholera had been seen in the village of Zebdjé, in Montenegro. It was added that the disease had been present there during the preceding 15 days.

Cholera in Austria-Hungary.

On July 31st the Austrian Ministry of the Interior issued a statement to the effect that between July 23rd and 30th 12 new cases of cholera had been registered in the province of Kuestenland, of which 11 had occurred at Trieste and 1 at Capodistria. In the following week (July 31st to August 6th) there were 14 more cases at Trieste, which was declared infected. Between August 7th and 13th 5 cases with 2 deaths occurred at Trieste, 6 cases with 4 deaths in the commune of Capodistria, and 2 cases with 1 death at Muggia; all these places are in the province of Kuestenland. The totals for the Austrian Empire since May 24th were then put at 50 cases of cholera with 19 deaths. Since then the existence of the disease has been reported from Fiume and from Budapest.

Cholera in Italy.

The following are the latest official returns of the cholera epidemic in Italy. Between July 22nd and 27th the disease was present in many places in the Naples province, including Naples itself; and in a smaller number of places in the provinces of Avellino, Benevento, Caltanisetta Campobasso, Caserta, Catane, Girgenti, Livorno, Palermo, Rome (1 case

only, at Civita Vecchia), and Salerno. The totals were not quoted. The later bulletins give the totals for all Italy as follows:—

From July 27th to August 1st	...	803	cases,	320	deaths.
,, August 1st ,, ,, 6th	...	1039	,,	389	,,
,, ,, 6th ,, ,, 13th	...	1737	,,	624	,,
,, ,, 13th ,, ,, 20th	...	1701	,,	659	,,
,, ,, 20th ,, ,, 27th	...	1684	,,	599	,,

In addition to the provinces above named, the disease had appeared in those of Genoa, Messina, Potenza, Venice, Syracuse, and Trapani. On August 22nd there were as many as 22 cases in Rome itself; and this is ascribed to a certain infected milk-supply.

Cholera in France.

Marseilles has so far been the only town in France in which cholera has been known to occur during the present epidemic. In addition to the cases already reported there were 3, occurring in a lunatic asylum, and 1 suspected case in the town on August 10th. (The local papers were quoted as reporting 27 cases with 12 deaths in this asylum.) On the 11th 6 new cases were seen (of which 4 occurred in the asylum); on the 12th there were 2 cases and 1 death; on the 17th 3 more cases were reported; and again 3 more on the 19th. Finally, from the 20th to the 23rd 7 cases with 4 deaths were stated to have been observed. Since then no further information has been received here. It may be added that the appearance of cholera in Tunisia is rumoured, but no official confirmation of the rumour has yet been received.

Constantinople, Sept. 6th.

FRENCH MEDICAL OPINION ON THE BRITISH INSURANCE BILL.

(FROM OUR SPECIAL COMMISSIONER.)

(*Concluded from p. 405.*)

Paris.

To the French medical practitioner, as already explained, the free choice of the medical attendant is the ruling principle governing all the actions of the organised members of the profession. It naturally follows that the Mutualist or Friendly Benefit Societies have become the chief obstacle to the realisation of this principle. Consequently anything which in the British National Insurance Bill would either increase or leave in the hands of Friendly Societies or clubs powers over the medical profession stands condemned in the opinion of French medical men. Any recognition, therefore, by the Bill of what are termed "approved societies" is looked upon with suspicion. Of course, there is no objection to Friendly Societies as such. Indeed, if imitation is the sincerest form of flattery the British Friendly Societies have no ground for complaint, for the medical profession itself in France has followed their example. The society known as the Concours Médical and the Medical Syndicates, or Unions, of France have created a number of mutual benefit or insurance associations, which provide to their subscribing members (all medical men) assistance in case of legal prosecutions, of illness, or old age, and on their death bring help to their widows and children. This is, the French medical practitioners maintain, the proper function of Friendly Societies, and they recognise by imitation the usefulness of such organisations. The difference arises, however, when the lay committees governing the Friendly Societies take upon themselves to organise, not merely the funds that are to provide financial assistance to the sick, but the medical services, employing medical men as hired servants, and imposing them on the patients.

French Mutualist and British Friendly Societies.

In England, however, the question may be asked whether the French Mutualist movement in its relations with the medical profession is sufficiently analogous with the growth of Friendly Societies and medical aid clubs in England to provide useful points of comparison. Both spring from the same humanitarian movement, which is sometimes called the school, a more or less romantic school, of 1848. The help that the Friendly Societies aim to give used to be supplied by the ancient guilds or trade corporations. These gradually fell into desuetude in England and were abolished in France by the decree of the Constituent Assembly dated June 14th, 1791. Societies for mutual help were then only allowed on the condition that they did not contain more than ten persons belonging to the same trade. This so crippled any organisations of the kind that from 1794 to 1806 there were only 13 such associations in Paris. The law of the Empire of 1810 did not allow any sort of association if it consisted of more than 20 members, but the Republic of 1848 granted entire freedom of association, and the embryo societies that had existed previously now budded forth. Under the Second Empire the objects of French Friendly Societies were strictly limited to sick insurance, and their organisation was placed absolutely under the dependence of the Government. Even for the General Association of the Medical Men of France the Government appointed the president. Napoleon III. could not trust medical men to elect their own leader. But under the Third Republic the freedom of association was restored, and the law of 1884 gave legal standing to trade unions and similar associations. Many trades unions in France, as in England, have a medical aid organisation. A law, dated April 1st, 1898, regulates anew the position of Mutualist Societies. The subscriptions collected by such societies, the law says, should serve to pay for help in case of sickness, for old age pensions, for accidents, funerals, and for relief of widows and orphans. Such are the objects, and so far so good. If this were the whole of the law the medical profession would warmly approve of the enactment. Then there are clauses which say that by means of special receipts or special levies the societies may pay for the organisation of technical classes, of agencies to find work for the unemployed and funds to relieve the unemployed. This, too, is very well, so far as it goes; but Article II. of the law stipulates that all members shall have the right to the same advantages. Theoretically, this also seems quite fair, but in practice it is very unjust and injurious to the medical profession, for it seems that a member, however rich he may become, shall have an equal right to medical aid which was organised to secure medical assistance to persons of very limited means. Thus, in France, there is a legal sanction to the abuse or grievance which is a matter of such constant complaint in England. Exactly the same sort of abuse occurs in France, and causes the medical men to urge that Friendly Societies should organise only the provision of financial relief in cases of sickness, but that the organisation of medical relief should be left to the medical men themselves. Medical men in France have therefore welcomed the taking of the distribution of medical benefits under the British Insurance Bill out of the hands of the Friendly Societies.

The French "Approved Societies" and Social Hygiene.

Another analogy between the French and English systems rests in the fact that there are in France also "approved societies." There are three sorts of Mutualist societies. First, free societies, which govern themselves as they choose. These have only a civil status, they can own no corporate property, must obtain a special authorisation to accept a legacy, and are not very numerous or important. Second, *sociétés approuvées*, whose statutes must receive Government sanction. Their expenses or liabilities must be covered by receipts recognised as sufficient. They may possess landed property, they may house their members, and the local authorities must lend them gratuitously a hall in which they can hold meetings. They are freed from certain stamp duties. But, on the other hand, they must invest their funds in Government securities, French railway companies, and other approved stock. Three-quarters of their property may be invested in land. Other measures are imposed by law, all devised to secure the solvency of the approved societies, and to make sure that the members shall receive all to which they are entitled. The State and the local authorities give subventions to these organisations, so that they are more wealthy and stable than any other similar bodies, but they are under such strict supervision and control that they are neither self-governed nor independent. The third sort of Mutualist societies have a programme corresponding to that which the Local Health Committees have imposed upon them by the British Insurance Bill. They consist of persons who, impressed by dreams of social progress, entertain views and promote plans of action that go far beyond the scope of ordinary friendly societies. Their intentions are so good that they are recognised by the State as societies of public

utility, which is a great honour, but offers no financial guarantee. Social hygiene is one of their principal objects. Without interfering with existing sanitary authorities, they endeavour to stimulate the action of such authorities. They try to recruit and provide trained nurses for poor localities, and organize popular lectures on sanitation. They help to bring about congresses and to secure the success of public meetings. They start dispensaries against tuberculosis or alcoholism, and find money to establish sanatoriums. Altogether, they are very ambitious, but their means being limited their action has not given rise to so many complications as might be expected. Still there is a good deal in the object and aims of this third category of Mutualist societies that recalls the social hygiene programme of the Local Health Committees, though the British Insurance Bill goes further and confers greater powers of interference with local authorities, employers of labour, and owners of inhabited property than the French Mutualists possess.

Mutualist Finance and Medical Expenditure.

Though the medical profession looks upon the Mutualists with great suspicion and some apprehension, they are not nearly so powerful as the corresponding Friendly and Benefit Societies of England. It is true they are numerous, though not so numerous as might be imagined, when their orators declaim about their millions of supporters. The Mutualist Societies of France do not number quite two million men, rather less than half a million women, and a little more than half a million children. The grand total just exceeds the figure of three million members. There are also 424,000 honorary members—that is, members who do not participate in the benefits. But their total capital is not much more than £16,000,000, or about £5 10*s.* per head. Dr. Bolliet, of Lyons, at the recent Congress of Medical Practitioners, presented some remarkable reports on the subject; he showed that half the Mutualist Societies did not possess 50 members and would not be able to survive an epidemic or some unusual catastrophe. Yet it is precisely these weak and unreliable societies that offer most of the opposition and raise the loudest complaints when efforts are made to introduce the principle of free choice of the medical attendant. The fact is that the subscriptions raised are altogether insufficient. The average payment to the approved societies does not amount to more than 10*s.* per head per annum. To the free societies the subscription is about 1*s.* more. This shows a falling off, for a few years ago the average was at least 12*s.* a year. The subscriptions paid by the honorary members have also decreased about 10 per cent., and they were estimated at only 10*s.* 8*d.* a year. In Germany the money paid to insure a workman against sickness is considerably above £2 per annum. In these circumstances it is not surprising if the payments made by French Mutualist Societies to their medical attendants only amount to about £162,000 per annum, or less than 8*s.* per patient. The cost of drugs and medical expenses other than the remuneration of the medical attendant does not fall far short of 12*s.* per patient. This outlay has a tendency to increase, while what is given to the medical practitioner is an ever-diminishing quantity. Consequently the medical profession does not hold the Mutualists in the highest esteem, and when the latter make eloquent speeches about the great deeds they intend to accomplish and the social reform that will result, their medical critics cruelly suggest that the first and most urgent reform should be the payment of higher subsciptions.

How it is Proposed to Render Good for Evil.

In 1908 a meeting was held between the representatives of the National Federation of the Mutualist Societies and the Union of the Medical Syndicates of France. M. Loubet, former President of the French Republic, presided, and it was agreed that mixed committees should be created in each department to assuage the conflicts between the medical practitioners and the friendly societies. The result has not been encouraging, for no compromise could be effected, the medical profession standing firm on the principle of the free choice of the medical attendant. This system, they maintain, has for its natural consequence payment per visit and per mile. The medical practitioner, it is urged, should ignore the existence of Mutualist or other similar organisations. At most he must not deal with them except as a sort of banking or collecting institution, which, in exchange for a small commission, will guarantee the payment of the medical fees. He may also aid Mutualist Societies to check malingering or the unnecessary increase of expenses that would arise if a member called on his medical attendant too frequently. In some societies this is checked by compelling the members to obtain a special ticket which they must show the medical officer. As a small charge is made for the ticket the member is less likely to resort to medical advice unless he is in real need of such assistance. This is a very important matter. One of the evils from which a medical officer of a medical aid organisation has to suffer is that members make calls upon his services with absolute want of consideration. It does not matter to the member or to his society how often the medical officer is called upon. But if, as is proposed, the medical officer is paid for every consultation then it would matter very much indeed to them both. Any such abuse would be of financial advantage to the medical officers, for they would have so many more fees to receive. Now, although the Mutualist or Friendly Societies did nothing to protect the medical officer when he was the victim and was unnecessarily overworked, nevertheless the French medical profession generously offered to return good for evil, and declare their readiness to help in establishing a ticket or any other system that will prevent the Mutualist Societies against being mulcted by unscrupulous members who otherwise might extravagantly increase the cost of medical attendance. Further, where abuse is supposed to occur there would be no objection to the nomination by the Mutualists of a medical representative and expert to investigate the case, so long as he observed the medical etiquette in regard to consultations and did not interfere with the treatment of the patients.

Mutualists Accept the Free Choice of Medical Adviser.

In this great struggle the Mutualists are themselves gradually coming round to the views promulgated by the medical profession. As matters now stand, many of them will not consult the medical officer of their society. If they can afford it, they pay fees and choose the private practitioner they prefer, while many of the club doctors hardly receive more than £6 a year, and therefore are not at all worried at the prospect of losing their appointments. In Paris alone there are 50 medical officers of Mutualist Societies who earn so small a sum that they really do not care what happens, at least, so far as their money interests are concerned. It has been calculated that the medical officers in the service of the Mutualist Societies receive from 1*d.* to 6*d.* per consultation, and the members themselves are realising that this is no pay at all. If, as a consequence, the patients are only superficially examined and errors result therefrom it would be difficult to complain. This is so well realised that a number of French Mutualist Societies have now agreed to accept the principle of the free choice of the medical adviser. An agreement is then drawn up and signed between the society and the local medical union or syndicate. A tariff for fees, small operations, accouchements, &c., is decided on according to the financial position of the members of the Mutualist Society or trade union in question. Any practitioner agreeing to these terms is free to inscribe his name on the panel, and the members have the free choice of those who are thus inscribed. Such is the evolution in the terms of contract practice which is actually taking place in France. The French practitioners are naturally anxious that the great insurance scheme proposed for England should not contain any clause that might be interpreted as discouraging the efforts made in France, and made with some measure of success. They view, therefore, the recent amendments with much satisfaction.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Death of the Chancellor of the University of Bristol.

Mr. Henry Overton Wills, first Chancellor of the University of Bristol, died on Sunday, Sept. 3rd, at his English residence, Kelston Knoll, near Bath. For some years indifferent health had kept him in retirement, and he was in his eighty-third year. His fellow citizens have ample reason for keeping him in grateful remembrance, and it is barely two years since the freedom of the city was conferred on

him. It will be remembered that Mr. Wills in 1908 made the foundation of the University possible by his splendid gift of £100,000. In recognition of his interest in the project he was appointed Chancellor of the new University, and although his ill-health kept him away from the various University functions he always maintained a lively interest in everything concerning the University, as various messages testify. His eldest son, Mr. G. A. Wills, is treasurer of the University. At the funeral service held at the Cathedral the University was represented by the Pro-Vice-Chancellor, Professor J. Michell Clarke, and members of the staff; and the robes of the Chancellor's office were laid upon the coffin. Representatives were also present from the Bristol General Hospital and the Queen Victoria Jubilee Convalescent Home, institutions to which Mr. Wills had contributed most liberally.

Bristol General Hospital.

The half-yearly general board of the hospital governors was held on Sept. 11th. The president, Mr. Joseph Storrs Fry, referred in his opening remarks to the loss that the hospital had sustained through the deaths of Lord Winterstoke and Mr. Henry Overton Wills, and also to Dr. H. G. Kyle's motor-cycle accident, mentioned a fortnight ago in these columns. It is gratifying to be able to say that Dr. Kyle's condition shows some improvement. The work done by the hospital is increasing, both in the wards and among the out-patients, as compared with previous years. Mr. Herbert M. Baker, the chairman of the committee, said that the ordinary income had increased by about £200, and that the legacies had also increased. Ordinary expenditure was also, unfortunately, greater by about £600, mainly owing to the increased cost of housekeeping commodities. The extension fund amounts to £42,365, so that a balance of £2635 remains to be collected before the sum of £45,000 is realised. Mr. Baker said that the committee had delayed the beginning of the building of the new wing until it was reasonably sure of the requisite funds. The plans have already been drawn up. The committee has decided to increase the remuneration of the nursing and resident staffs.

Post-graduate Classes in Pathology at Bristol.

During the past summer the University of Bristol made a new departure in the post-graduate teaching of pathology. Professor I. Walker Hall gave a series of lectures and demonstrations to a class of about 20 practitioners at Frome. This class was so successful that it has been decided to hold similar courses at Dorchester and at Taunton during the autumn. A short course of practical demonstrations by the professor and demonstrators of pathology is also advertised to take place at the University during September and October.

A Case of Cerebro-spinal Fever in Bristol.

Recently a child died in Bristol from cerebro-spinal fever, apparently acquired during a holiday visit to the infected area in North Cornwall. No other cases have been reported as a result of this one, but the chairman of the health committee proposes to ask the council to give its sanction to the inclusion of cerebro-spinal fever and acute anterior poliomyelitis among the notifiable infectious diseases for a period of six months, if the Local Government Board approves.

Death of Mr. Henry Robbins Dew.

Mr. H. R. Dew, consulting surgeon to the Bristol Eye Hospital, died at his residence, Stanton Wick House, Stanton Drew, near Bristol, on Sept. 6th, in his seventy-eight year. Mr. Dew was born at Warwick in 1834, and afterwards came to Bristol, where his father was an attorney-at-law. His grandfather, Dr. James Dew, was a well-known medical practitioner of Bristol; his great grandfather was John Dew of Coleford, Gloucestershire; and the family have owned for many generations a manse at Coleford, in which it is said that Charles I. took refuge on one occasion. Mr. Dew received his medical education at St. George's Hospital, and qualified as M.R.C.S. in 1855. Six years later he obtained the L.R.C.P. of Edinburgh. He served in the Crimean war, and was staff assistant surgeon to Lord Raglan. On his return he commenced practice at Bristol, where he soon established a large connexion. He held several public appointments, being at one time honorary surgeon to the Bristol Eye Hospital, surgeon to the Deaf and Dumb Institution, the Blind Asylum, and the Lying-in Institution. About 12 years ago Mr. Dew retired from all active work and took up his residence at Stanton Drew, Somerset. The funeral took place at Arno's Vale Cemetery, Bristol, and was largely attended.

The Tiverton (Devon) Board of Guardians and Pulmonary Tuberculosis.

The Local Government Board has granted permission to the Tiverton board of guardians to treat "consumptives" in huts to be placed in the open ground of the workhouse infirmary, provided that the necessary precautions are adopted.

The Health of Devon in 1910.

The annual report of the medical officer of health for the county of Devon (Mr. G. Adkins), which has just been issued, states that during 1910 8709 births were registered, equal to a birth-rate of 19·2 per 1000, compared with 20·0 for 1909. The deaths numbered 5810, giving a death-rate of 12·8 per 1000, against 13·4 in 1909. The infantile mortality was 67 per 1000 births, against 76 for the previous year. The infant illegitimate death-rate was 17·6 per cent., against 7·1 per cent. for those infants born in wedlock. 1070 cases of disease had been notified, against 1470 in 1909, including 402 from scarlet fever with 8 deaths, 412 from diphtheria with 49 deaths, and 75 from enteric fever with 10 deaths. No case of small-pox was notified. 551 deaths were due to tuberculosis, including 416 from pulmonary tuberculosis. 453 deaths were caused by cancer.

Hospital Saturday at Newton Abbot (Devon).

As a result of the Hospital Saturday collections the sum of £194 has been handed to the treasurer of the Newton Abbot Hospital. This is £28 less than the sum allotted in 1910.

The Paignton Mortuary.

At a recent inquest held in Paignton, the medical man who performed the post-mortem examination complained of the state of the mortuary, which he described as scandalous and filthy. He added that it appeared to him "almost an insult to the dead to take them into such a horrible place." The coroner agreed with these remarks, and the jury added a rider to the same verdict, recommending the district council to erect a suitable mortuary.

Sept. 12th.

WALES.

(FROM OUR OWN CORRESPONDENT.)

The Water-supply in Glamorgan.

WHILE certain parts of the county of Glamorgan, including Swansea, Merthyr, Aberdare, Pontypridd, and the greater part of the Rhondda valleys, have not been affected by the recent drought, there are other parts in which the conditions are more or less serious. The Cardiff supply, which is normally obtained from gathering grounds in the Brecknock Beacons, has had to be supplemented from deep wells owned by the corporation and situated at Ely, within a few miles of the town. From this source about a million gallons daily is available. The watering of gardens with hose-pipes has been prohibited in Cardiff, and the inhabitants have been asked to be as careful as possible in the use of water. Unless there is a sufficient rainfall during the next few weeks, it is anticipated that further steps will have to be taken to conserve the supply. The Swansea waterworks have now been completed by the construction of two covered service reservoirs, each holding two million gallons. The resources of the Swansea waterworks are capable of supplying nearly 70 gallons per head of the population daily.

The Housing Question.

In spite of the acknowledged lack of suitable working-class dwellings in many parts of South Wales, very few sanitary authorities have taken advantage of their statutory powers to provide such dwellings. Amongst the few that have done so is the urban district of Gelligaer near Merthyr. When proposing that the council should take action under Part III. of the Housing Act, 1890, a member of the council stated that in one street of 50 houses in a certain locality there were no less than 420 persons. He attributed the overcrowding to the high rentals which were demanded, so that two or three families were obliged to occupy one house.

Neath Rural District.

The conditions described by Dr. S. W. Wheaton, in his report to the Local Government Board on the sanitary circumstances and administration of the Neath rural district, are most discreditable to the local sanitary authority. The population of the district has increased from 29,000 in 1901 to over 42,000 in 1911, but in only three localities is there any systematic sewerage. In two of these the sewage passes untreated into the tidal river Neath, and in the third the proprietor of a colliery at his own cost has sewered 50 houses and constructed septic tanks and bacterial filters. In the greater part of the district liquid refuse escapes into streams, ditches, or roadside channels, or, after running in surface channels for some distance, soaks into the subsoil. Many of the houses drain into soakaway cesspools, with the result that the ground beneath the dwellings is becoming saturated with filth, which, as Dr. Wheaton very properly states, may have injurious effects for some time even after the premises have been properly sewered. The contents of the privies which abound in the district are removed by contractors, but in many instances the filth is buried in a hole in close proximity to dwellings, and so small is the area available for this purpose that it frequently happens that any attempt at covering it with earth is impossible. Few of the houses have water laid on to them. In most instances it has to be carried by hand from standpipes which are 50 to 150 yards and upwards distant. The smaller sources of supply are liable to pollution. Three years ago an outbreak of typhoid fever involving 26 cases was due to the use of water from old mine workings which had become polluted by surface soakage. Dr. Wheaton recommends the council to proceed at once with the work of sewering the most populous parts of the district, and to dispose of the sewage in such a manner as not to pollute the watercourses. He also advises the council to undertake the scavenging of the district itself in place of the present system of contracting, to provide an efficient hospital for the isolation of infectious diseases other than small-pox, and to give more attention to the condition of the dairies and cowsheds in the district.

Sept. 12th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Donation to Aberdeen Dispensary.

IN response to an application from the directors of the Aberdeen Dispensary the town council has decided to give a donation of £750 to the institution. It was pointed out that over 15,000 cases had been dealt with in the dispensary last year. Many such cases, in the opinion of the committee, should have been treated at the Royal Aberdeen Infirmary, but a large number took advantage of the institution who were quite able to pay for medical advice and medicine. In view of the fact that the dispensary did a great amount of good to the poorer classes of the community, and also that the Lord Provost had intimated that if a liberal donation were given by the town council he could see his way to get a sufficient sum to clear off the present debt of £5000, the committee considered it was justified in recommending the council to give a donation of £750. The institution has not received a donation of any kind from the council during the last 60 years.

Aberdeen Infirmary and Water Charges.

The present charge for water made to the Royal Aberdeen Infirmary was fixed in 1892, and is covered by the moderate sum of £10 per annum. The water committee of the Aberdeen town council considers, however, that since then circumstances have materially altered. From the information before the committee it appears that the quantity of water now used in connexion with the Royal Infirmary amounts to about 14,000,000 gallons per annum, of which one-fourth is used for other than domestic purposes, such as steam heating, mechanical ventilation, hydraulic lifts, laundry, &c. The terms upon which the Aberdeen town council supplies water to public institutions within the city have been under consideration, and after Nov. 30th it is proposed that the infirmary should pay for its water on the following terms: (1) For the water used for the ordinary purposes of the infirmary, such as steam heating, mechanical ventilation, hydraulic lifts, &c., at the rate of one-fourth of the ordinary rate for supplies by meter within the city, as such rate may be fixed from time to time by the council; (2) for the water used for generating steam for electricity, the ordinary rate for supplies by meter within the city. On Sept. 5th a deputation of directors waited on the water committee with reference to the proposed change, when the matter was remitted to the water engineer to bring up a report upon the amount of water used by the infirmary and for what purposes; upon this the water committee promised to reconsider the whole matter.

Montrose Royal Asylum: Proposed Reduction of Attendants' Hours.

At the monthly meeting of the managers of Montrose Asylum and Infirmary Board held on Sept. 6th, a motion to the effect that the hours of the attendants at Sunnyside Asylum be reduced, and the principle of superannuation approved of without the intervention of Parliament, was unanimously carried. It was decided, however, to allow the matter to lie over until the result of the approaching conference on the Asylum Officers' Employment and Superannuation Bill is learned, after which it will be remitted to a special committee for consideration and report.

Arsenic Poisoning at Lamlash.

Last week, in the Sheriff Court at Rothesay, an inquiry was made into the mysterious epidemic of sickness which broke out at the end of April in the village and district of Lamlash in the island of Arran, and resulted in the death of a boy, the other sufferers all recovering after more or less severe illnesses. Investigations showed that death was due to arsenical poisoning, and that it was caused by the eating of a scone made in the bakery of a local firm. The firm instantly took steps to trace the poison, and in this they were assisted by the police authorities and prominent analysts. Arsenic in alarming quantities was found in samples of scones taken from the same batch as that from which the scone eaten by the child was taken. In the course of the evidence it was stated that one scone alone contained enough arsenic to kill three persons. Exhaustive inquiry and analyses of all materials used in the bakery demonstrated that these were all perfectly pure. This led to the belief that the poison got into the foodstuff while that material lay overnight in the prepared state ready for the beginning of the morning's baking operations. The various employees of the firm, as well as the sole partner, were unable to offer any opinion as to how the scones became tainted. The sheriff, in addressing the jury, said the poison could not have found its way accidentally into the scones. He spoke highly of the manner in which the baking business was conducted, as appeared from the evidence, and also of the assistance rendered by the firm and the employees to the authorities in their investigations. He counselled the jury to return a verdict leaving everything connected with the case open. It was then possible for the Crown to take steps subsequently if that course was found justified. The jury returned a simple verdict that the child died from poisoning by arsenic, adding that they believed the firm to be entirely free from blame in the matter.

Dunoon Convalescent Homes.

The forty-second annual report of the directors of the West of Scotland Seaside Homes, Dunoon, has just been issued. During the past year 4993 patients were admitted, exclusive of children under two years of age. Of these, 4690 were restored to health, 173 relieved, 112 did not improve, 1 died, and 148 remained in the homes. The total number of persons admitted since the homes were opened in 1869 was 135,179. These homes undoubtedly fulfil a very useful function in admitting patients not fit for their work and not yet ill enough to be admitted to hospital. The majority of the male patients during the year were skilled workmen, while young mothers and warehouse and factory girls formed the majority of the female patients. The ordinary income for the year amounted to £7581 and the ordinary expenditure to £6607.

Medical Officer's Report anent Ythanwells and Corse Schools.

The Ythanwells school board met on Sept. 2nd, when the chief medical officer's report on the schools was submitted. In it the attention of the school board is drawn to the condition of the playground of the Ythanwells school, as

follows: "The playground was in a very bad condition, and was more like a bog than a playground." Of the Corse school it is said: "The heating of the senior class-room is insufficient; there are no shelter sheds for the children; and the desks in the infant school are quite insufficient and ought to be replaced by up-to-date ones." Commenting on the report, the board felt that if the recommendations were to be carried out it would cost several hundreds of pounds. With regard to the heating of the senior class-room at Corse, it was pointed out that the board had divided the schoolroom by a partition and had had an extra fireplace put in, so that in the place of the one fireplace, which had been deemed sufficient for many years, there were now two. With reference to the playground at Ythanwells, the board took exception to its being called a bog, and considered it satisfactory. After discussion the chairman proposed that, in view of the state of the school fund and the small and steadily decreasing valuation of the school district, and the ever-increasing school rate and demands of the department, involving additional heavy expenditure, the school board take into consideration at a future meeting the discontinuing of Ythanwells as a school district, under the provisions of Section 22 of the Educational (Scotland) Act, 1908; and alternatively, that an all-round reduction of salaries be considered, so as to keep the school rate at a reasonable level. The meeting agreed to have up-to-date desks supplied to the infant department at Corse school.

Sept. 11th

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Lunacy in Ireland.

IT is terrible to note that whereas in 1880 there were only 250 insane per 100,000 population in Ireland, the proportion has continuously risen (though less markedly in the past few years) until, according to the recent report of the Inspector of Lunatics on Jan. 1st, 1911, the figures reached 558 in each 100,000.

Post-graduate Classes at Trinity College, Dublin.

The autumn post-graduate medical course for 1911 will begin on Sept. 25th. The course will be conducted on similar lines to those of past years. Instruction will be given in the various departments of medicine and surgery, and particular attention will be paid to special subjects, such as ophthalmology, laryngology, and dermatology. There are also classes in X ray work and cystoscopy. The course is primarily intended for general practitioners, and the aim of the teachers is to make the demonstrations as practical as possible. The time-table is so arranged that each member may attend all the classes. Work generally begins at 8.30 A.M. and is continued with an interval for luncheon till 5.30 P.M. The social side has not been entirely overlooked, as arrangements have been made by which a limited number of members of the class can reside in College rooms and dine in hall. This privilege is open to all members of the class as freely as to graduates of the University. A complete syllabus may be had on application to the honorary secretary.

Flies and Disease.

Sir Charles Cameron, medical officer of health of Dublin, has persuaded the public health committee to pay for the destruction of flies. Paper bags have been distributed, each of which is capable of holding some 12,000 flies, and the committee pays a few pence for each bag returned full of dead flies. This seems to be attacking the fly nuisance from the wrong end, for, as a correspondent points out in the daily papers, if the streets, lanes, and courts of the city were kept clean there would be comparatively few flies to deal with. In spite, however, of much criticism, the scavenging of Dublin is still very imperfectly performed. Meantime the death-rate is 27·6 per 1000.

Health of Belfast.

Advanced copies of the annual report of Mr. W. H. Bailie, medical officer of health of Belfast, have just been issued dealing with the year 1910. It is a pity this report is belated, as the population of Belfast, on which the vital statistics are based, is taken as that of the old approximate figures of the Registrar-General, 391,167, while the real figures, as given three months ago—after the Census of 1911—are 385,492; that is, the actual population of Belfast is nearly 6000 less than the estimated one. Taking the figures as they are given in the report, the natural increase of population—i.e., the number of births in excess of deaths—was 3604, being 268 less than in 1909, and 172 less than the average for the ten preceding years. The birth-rate of Belfast, like that of most other large cities, shows a steady and continuous decrease from 33·4 per 1000 in 1881 to 27·8 per 1000 in 1910. 7284 deaths from all causes were registered; which is equivalent to 1 in 53, or 18·6 per 1000 of the population, and is 0·4 higher than the rate in 1909, but 1·8 below the average rate for the ten years 1900–1909. The number of deaths from zymotic disease was 1073 (562 in excess of those in 1909, and 267 in excess of the average for the ten years 1900–1909). The rate (2·7) is 1·4 per 1000 higher than in 1909, and 0·5 higher than the average for the preceding ten years. This increased zymotic mortality is due to an epidemic of measles from which 504 deaths occurred, corresponding to a rate of 1·3 per 1000. There is a reduction in typhoid fever (only 18 deaths occurred in 1910), only one death occurred from typhus fever, and although 734 cases of scarlet fever were notified (there being an epidemic which began in October, 1909, and continued during 1910, largely among children of school age) only 18 died, a mortality of 0 04 per 1000. Diphtheria caused 27 deaths out of 233 cases notified, a mortality of 11·1 per cent. More than half of the cases of puerperal fever notified (16) occurred in districts where the practice of unqualified midwives is most prevalent. Eleven of the cases were attended by "handy women," and in only two of these 11 was a medical man in attendance from the beginning. Nine deaths occurred. It is hoped that the clauses in the contemplated Belfast Corporation Bill dealing with this subject will put an end to such evils, or at least will greatly mitigate them. 259 deaths (46 in excess of 1909) occurred from whooping-cough, the annual rate of mortality being 0·6 per 1000 of the population, while there were 504 deaths during the year from measles, being equal to a rate of 1·3 per 1000. This is almost the highest rate for 30 years in Belfast, the exceptions being the years 1885, 1890, and 1894, and the epidemic was prevalent all over the city. 241 deaths were due to diarrhœa. 929 cases of tuberculosis were notified pursuant to the Tuberculosis Prevention (Ireland) Act, 1908, and in addition 244 cases were notified voluntarily. 825 deaths occurred in 1910 from tuberculosis, as compared with 811 in 1909, the rate in both instances being 2 1 per 1000 of the population. It is unfortunate that the disease seems not to be decreasing in Belfast. In reference to infantile mortality, the rate was 143 per 1000 births (1553 deaths), as compared with 139 (1510 deaths) in 1909; figures showing an increase of 4 per 1000, which is very disappointing. It is unfortunate that practically two-thirds of the milk-supply of Belfast is produced in districts outside the city, which are beyond the jurisdiction of the health authorities. Attention is again drawn to the abominable double-tenancy houses, and the report advises "the erection of specially designed houses where one or more rooms can be let to people who are unable to pay more than from 1*s.* to 2*s.* per week for rent," adding that power should be "granted to the local authority enabling them to prevent owners letting houses to more than one family where sanitary conveniences are not provided for each letting." This annual report on the health of Belfast for 1910, though less elaborate and exhaustive in tables, diagrams, and in comment than some of previous years, is a valuable document. It occupies 157 pages, as compared with 230 in the report of 1909 and 198 pages in that for 1908. An index would have been a decided improvement.

Dungannon Workhouse.

As a result of a recent Local Government Board inquiry at Dungannon workhouse, that Board state that, in their opinion, the hospital arrangements require the careful consideration of the board of guardians with a view to their improvement, and that measures should be taken to remedy defects which have been shown to exist in the management of the infirmary.

Death of William Twigg, M.D. R.U.I.

Dr. William Twigg died on Sept. 11th, after a very long illness, at his residence, Northland-road, Dungannon. The

deceased gentleman, who had attained an advanced age, was a member of an old county Tyrone family. Qualifying in 1861 as L.R.C.S. Irel., he took the M.D. of the Queen's University of Ireland in 1862, and immediately began practice in Dungannon. In 1864 he was appointed medical officer of the union workhouse and fever hospital in that town, a position he held until his death. He had also been Surgeon-Lieutenant-Colonel of the Mid-Ulster Artillery for many years, retiring only in 1901, with permission to retain his rank and wear his uniform. The deceased gentleman had been a useful member of the old board of Dungannon town commissioners, and often acted as churchwarden and select vestryman in the local parish church. He had a large private practice and was greatly respected. He was buried in Dungannon on Sept. 13th.

Death of Judge McIlroy, K.C.

Great regret has been expressed on all hands at the sudden death of Mr. Robert McIlroy, K.C., recorder of Belfast and county court judge for Antrim, which occurred from the rupture of an aneurysm on Sept. 6th. As the judicial authority before whom cases of workmen's compensation were tried, he had much work to deal with in a great city like Belfast, and his decisions gave the utmost satisfaction not only to workers, employers, and lawyers, but also to medical men who appeared before him. His knowledge of law and his care and patience were supplemented by sound sense and humour. He was a distinguished former student of Queen's College, Belfast, and at the last annual dinner of the Ulster Medical Society he was one of the invited guests, and made a very able speech.

Sept. 12th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Cremation.

THE cholera epidemic, which, starting in the East, has extended to this country, has given rise to animated and wordy discussions with regard to cremation. The partisans of cremation regard it as the sole means of securing by one procedure both the disposal of the bodies and safety from ultimate contamination of the soil. Its opponents, however, raise many objections, of which the principal one is that incineration, in destroying the corpse, destroys also every trace of poison, and thus promises immunity to criminals. In support of their case they cite arsenical poisoning, a condition that presents all the symptoms of cholera. If the bodies were cremated, toxicological investigations would become impossible in such cases. On the other hand, in the case of an accused party, or even of one suspected of this crime, earth burial would leave it possible for the accused to prove his innocence, whereas cremation would make it impossible to dissipate entirely the suspicion that always clings to the accused. Those who attach weight to this objection demand, therefore, that every cremation should be preceded by a necropsy. But here a fresh difficulty obtrudes itself, in that a necropsy in cases of poisoning offers no precise data unless accompanied by a toxicological examination, which may require three months. Consequently, a law which entailed a necropsy with a toxicological examination prior to cremation would necessarily render cremation impossible, so that such a law would be equivalent to a prohibition of cremation itself. Attention has therefore been centred on searching for a means capable of affording a sufficient guarantee without imposing too great obstacles to the practice of incineration. M. Sicard of Marseilles, who has paid special attention to this question, has made experiments on the humours of the eye, the bile, the urine, and the cerebro-spinal fluid, and has found the quantity of poison present in the eye to be even greater than that found in the other media of the body. If 30 drops of Fowler's solution are injected into a rabbit weighing 500 kilogrammes, 10 drops every eight hours, and the animal is killed eight hours after the third injection, the quantity of arsenic recovered M. Sicard finds to be as follows: in the brain, 0·3012 mg.; in the kidneys, 0·024 mg.; in the liver, 0·06 mg.; and in the media of the eye, 0·071 mg. M. Sicard, then, proposes to remove by aspiration from a corpse intended for cremation the following physiological body fluids: the aqueous and vitreous humours, bile, urine, and cerebro-spinal fluid. The fluids should be kept in small phials, which can be placed in the funeral urn or the box intended for the ashes. Thus important evidence will be preserved, so that practically an exhumation can be made later if necessary. At the present time, says M. Sicard, the use of only the bile and the urine is to be recommended, for it is difficult to induce the family to agree to meddling with the eyes; and, on the other hand, researches demonstrating the passage of the substances absorbed into the cerebro-spinal fluid in the normal condition are not sufficiently numerous to justify the drawing of any decided conclusions in so grave a question. A part of the substances taken into the organism is recoverable from the bile, and the kidneys are the most active and powerful agents in the elimination of poisons. Nearly all poisons pass off in the urine, and for many of them it is the principal channel of elimination. The urine could be collected from a corpse by means of an aspiratory puncture with the kind of aspirator used in lithotrity, or recourse could be had to aspiratory puncture of a vein, which would permit of obtaining a certain amount of blood or of sero-sanguineous fluid. But M. Sicard prudently adds that no experiment should be accepted as definitive before the advantages that he claims for it have been confirmed by other authors.

The International Sanitary Conference, 1911.

The International Sanitary Conference to revise the provisions of the Convention of 1903 to prevent the invasion and propagation of plague and cholera will take place at Paris on Oct. 10th next.

Sept. 12th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The New Medical Act.

THE work of the Union of the Austrian Medical Corporations was concluded a few weeks ago, and the outcome in the shape of resolutions has now been brought to the notice of the Government. The paramount demand of the profession is, that before the final framing of the proposed new Medical Act (Aerzte-Ordnung) practising members of the profession should be asked for their opinion, and not only medical officers of health, who with us are somewhat in the position of Government officials. The profession demands that compulsion to practise shall be abolished as it is useless to the public and a menace to the profession, and that doctors of medicine shall be made independent of lay opinion and lay judgment in all affairs pertaining to the practice of medicine. The profession also protests against being placed in the dilemma that one law demands from its members absolute professional secrecy, whilst another clause of the same law makes this secrecy illusory. They demand that the new law should abolish Section 359 of the present Civil and Penal Code, by which a medical man is forced in certain circumstances to give information against a patient who has sought his professional help. Such a law makes the medical man act the part of a police spy—a position against which the entire profession vehemently remonstrates. The confidential nature of the relations between the medical adviser and the patient must be carefully guarded by the new law, as the continuance of professional secrecy is of the highest importance to the public, the State, and the medical practitioner.

Use of Antivenomous Serum in the Army.

In the southern parts of the Austrian Empire there are several kinds of poisonous serpents, and the soldiers stationed in these districts are frequently bitten; last year four men lost their lives and seven were seriously indisposed from this cause. The chief medical officer of the army corps stationed in this part of Austria has recently ordered the use of Calmette's serum against serpent-bites, and a fairly large stock of it has now been issued to each regiment in the south. The men and the medical officers are instructed how to use it, and regular inspections of the stock, as well as lectures on the natural history of the poisonous kinds of serpents, are provided for. In addition to the serum, the various appliances necessary for its proper application have

been supplied to the army hospitals. Much reliance has hitherto been placed on the treatment of such injuries by alcohol and the application of permanganate of potash. The present unusually protracted period of hot, dry weather has been very favourable for the multiplication of serpents in the localities infested by them, so that the extra precautions were not superfluous.

The Austrian Society for the Prevention of Diseases.

A society for the prevention of diseases and epidemics (Gesellschaft zur Bekämpfung von Volksseuchen) has been founded in Austria, and will act in concert with the Public Board of Health and the Sanitary Department of the Ministry of the Interior. Its aims are to supplement the endeavours of the public authorities in combating diseases, to improve the general circumstances of patients and their families belonging to the poorer classes, to provide adequately trained attendants for the care and nursing of patients during epidemics, and to organise medical help and hospital accommodation in non-epidemic times. The society will also encourage investigations relative to the spread of diseases, as well as their prophylaxis and treatment, and will, as far as possible, make the general public acquainted with the results of these scientific researches. The society will endeavour to improve our knowledge not only of the so-called epidemics, but also of all diseases which prevail extensively among the population. All infectious diseases, including sexual diseases, will therefore receive attention from the society. The necessary funds are to be obtained by lotteries, by "hospital days," by collections, by charitable grants, and by Government subsidies. The present intention is that the scientific part of the work shall be divided amongst all practitioners in the country through the instrumentality of the local medical unions and councils. It is thought possible that an international society for the study of epidemic diseases may in the course of time be called into existence. The present menace of cholera, which threatens the whole south of Europe and also all the commercial centres of the civilised world, is a valuable instigation to the task of the society, in so far as it shows that much good work may be done within the limits of a reasonably restricted programme.

The Austrian Section in the Hygiene Exhibition at Dresden.

Great dissatisfaction is felt in this country with reference to the appearance of the Austrian Section of the International Hygiene Exhibition in Dresden. The actual condition of public hygiene and practical medicine, as well as the general position of this country in all matters pertaining to public health, are seriously misrepresented there, and several independent observers have not been very lenient in their criticism of the matter in our journals. The fault was, from the beginning, the predominance of what may be called bureaucratic influence, whilst the medical profession as a whole was in no way considered by the Government when preparations for the exhibition were going on. Remonstrances coming from non-official persons are not much thought of by our officials, and it has required an expression of public indignation to call the attention of the responsible authorities to the unsatisfactory state of this portion of the exhibition.

Sept. 11th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Cholera Epidemic in Italy.

A CHANGE for the better is now manifest in the cholera-visited cities and communes of Italy. Leghorn has hitherto been the greatest sufferer, thanks to its insanitary condition and the supineness which left to local initiative and intervention what ought to have been anticipated by direct measures inspired and carried out by the Central Office. Leghorn has actually reduced by more than one-half the percentage of reported seizures and deaths. The maritime communities south and north of that seaport also give improved returns, while the landward towns, particularly such as Florence, Siena, and Lucca, are still practically immune. As in all such visitations, the predisposed of the population, the "candidates," so to speak, are picked off first, and thereafter the less predisposed, having profited by the warning, have either betaken themselves to healthier localities or have adopted measures, reinforced by a more vigilant sanitary surveillance, to fortify themselves against attack. With this, panic subsides, and a powerful auxiliary of the disease is thus removed from the scene of its operations. Cholera may now be said to be in full retreat.

The "Congresso Forestale" at Turin.

At Bologna in 1909, at Florence last year, and now at Turin, in connexion with the exhibition and the *festa* in commemoration of the fiftieth birthday of the "Third Italy," the reafforestation of the country has been the subject of largely attended congresses, at which the crying necessity for extensive and systematic silviculture was amply discussed. Like all the States along the Mediterranean seaboard, Italy has suffered disastrously by the reckless tree-felling, uncompensated by tree-planting, prolonged through centuries, till her condition has become only less pitiable than that of Spain, which lost her mercantile marine by the improvident using up of her timber and the reduction of the majestic forests, eulogised by Martial, to naked sierra or thinly clad prairie. Germany and Austria-Hungary have shown Italy the example of jealously conserving their forest growth, while Switzerland, driving home the lesson, has utilised Italy's own invention, that of electro-dynamics, by turning the water-power evolved from the rivers to the development of the lucrative steel and iron industry. This water-power is kept going by the enlightened silviculture which, by its equable production and storage of moisture, has made the Swiss side of the water-shed a perennial reservoir, while that of her southern neighbour is prolific only in autumnal floods, which leave the rivers, after their short-lived repletion, little better than gravel-pits for nine months of the year. Italy's climate, too, like that of Spain and Greece, has changed for the worse by the denudation of her hillsides—incurring in that, as in so many other directions, the nemesis of what Virgil calls the "justissima tellus," which, loyally treated, repays the cultivator with blessings ample and unfailing; which, on the other hand, neglected or abused, visits such treatment with relentless retribution. All this, and much more, recapitulated with commanding eloquence by the ex-Premier Luigi Luzzatti, who presided at the Turinese Congress, led up to a reassuring demonstration of what an awakened Italy is now doing to atone for her improvident past—a demonstration confirmed and illustrated by the able and accomplished Minister of Agriculture, Signor Nitti, who enlarged on the intimate dependence of the country's water-supply on the maintenance of its forest growth, and showed how public hygiene is not less interested in the problem of reafforestation than the national resources generally. The proceedings, carried into the subsequent sittings, evoked much valuable comment on the various methods of reclothing the despoiled uplands, while formulating practical suggestions for meeting the financial difficulty in bringing the pastoral rights established in those uplands under the control of Government by compensation or redress.

Sept. 10th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Cholera in Hungary.

Dr. Magyarevics, chief medical officer of the city of Budapest, speaking in the Medical Society on the subject of cholera, said that three cases of the disease had been recently notified in Budapest, but there was not as yet any appearance of its extending further. In Mohacs, where about 25 fatal cases occurred in 1910, there had not been a single case of cholera notified since the beginning of the present year. The vigorous efforts of the board of health in checking this outbreak deserved the highest praise. Dr. Magyarevics further said that in his opinion quarantine and detention camps were of little if any value for the prevention of cholera. The poorer classes required special attention, and there ought to be full disclosure of the facts as soon as cases appeared. No method of treatment giving satisfactory results had been discovered, although intestinal antisepsis promised well; all water should be boiled, no uncooked food should be eaten, and the contents of the stomach should be kept acid by the drinking of lemonade or lime-juice, or else of water or tea containing a little diluted hydrochloric acid, because the spirilla of cholera could not

live in an acid medium. The water-supply should be carefully guarded; and all drains, latrines, cesspools, and places where filth was apt to accumulate should be cleaned and disinfected. In the report of the public health board of the city of Budapest for 1910 Dr. Magyarevics has made an exhaustive study of the present state of knowledge relative to protective inoculation against Asiatic cholera. The principal conclusions to which his inquiries have led him were as follows: (1) When spirilla of cholera were subjected to autolytic digestion in an aqueous fluid the receptors became separated from the bacterial cells and might be filtered in solution; (2) the subcutaneous injection of such free receptors into the human subject was free from any danger and produced only slight general reaction; and (3) the method was therefore a practical one for producing a cholera-immune serum in man.

Tuberculosis and Poverty.

Much valuable information relative to the prevalence of tuberculosis among the poorer classes will be found in a small book which Dr. Berkovics has published on the various problems involved in the prevention of tuberculosis. Prominence is given to the fact that every year in Hungary this disease causes 70,000 deaths, or one-seventh of all the deaths. The figures show that a close relation exists between the social position of the patients and the number of deaths. It is found that four times as many cases occur among the poor as among those who are in comparatively favourable circumstances, and Dr. Berkovics says that this makes the problem of limiting the malady a part of the larger social problem of dealing with poverty. The efforts to limit the disease are discussed under two principal heads—namely, the public control of general health conditions, as exercised in cities, and the more immediate practical efforts directed to the medical care of infected persons. An idea of the prevalence of the disease, modified somewhat by the increased attention given to it in recent years, may be gained from the following statistics. The total number of patients treated in 1900 was 3728, in 1905 it was 4910, and in 1910 it was 5344. The expense has also about doubled, rising from 1,200,000 kronen in 1900 to 2,000,000 kronen in 1909. The most promising step that has been taken for the improvement of existing conditions was the organisation in 1902 of a central committee for establishing hospitals for tuberculous patients. The chief problems recognised are the destruction of the bacilli and the separation of tuberculous patients from other persons. The inherent difficulties of these two problems are increased by the presence of poverty, crowded habitations making infection more frequent among people who have no proper means of caring for the sick.

Acute Articular Rheumatism in Children.

Dr. Gross, writing in the *Orvosok Lapja* of August 17th, enumerates quite a goodly number of authors who have reported cases of acute articular rheumatism in very young infants, although it is known that this condition is comparatively rare in children several years of age. In his opinion the disease may perhaps be transmitted with the milk of the nurse. The incubation period in such cases is at least four days; the duration of the disease is between two and four weeks; and both the duration and the severity of the disease are less in infants as compared with adults. Implication of the pleura and of the nervous system (chorea) is of frequent occurrence. This has been reported by Baudelocque, by Rilles and Burthez, and by others. Picot found that 50 per cent. of the cases observed by him were complicated with pericarditis, while Bokay in Budapest asserts positively that the heart of every rheumatic child is found to be attacked sooner or later. Dr. Gross observed in one case a rather rare complication in the form of an effusion into the maxillary joint.

Sept. 11th.

THE DEVIZES (WILTS) HOSPITAL.—A tender for £1838 has been accepted for the enlargement and alteration of the Devizes Hospital. This is to be erected as a memorial to the late King and also as a Coronation Memorial. About £2000 has been subscribed for the scheme, including a gift of £1000 from Mr. Grant Meek, the chairman of the hospital committee.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

The Attack on Dr. Wiley.

THE country at large has taken a long breath of relief at the collapse of the case against Dr. Wiley, whose activities against adulterated food had made him a host of powerful enemies; so powerful, indeed, that they had succeeded in foisting on him a colleague who was able completely to nullify his prosecuting work. The main force at work against Dr. Wiley is thought to have emanated from the fruit packers of California, who maintained that the prohibition of the use of sulphur dioxide for bleaching tinned fruit would damage their industry to the extent of £2,400,000 annually. Another strong party against Dr. Wiley were the manufacturers of tomato ketchup, who were anxious to use sodium benzoate in their sauces, their contention being that the salt was not inimical to health. Dr. Wiley, however, pointed out that its use enabled criminally careless manufacturers to incorporate floor sweepings and other refuse in their products without the possibility of fermentation betraying the presence of dirty ingredients or foreign material. Thoroughly to understand the situation it must be remembered that there are millions of people in the United States who will not use a sauce that contains alcohol, one of the best of preservatives. It is therefore necessary for the makers either to go to the expense of absolutely pure and fresh ingredients, sealing them up while hot, or to check fermentation by some chemical preservative; for, above all, it is indispensable to their trade prospects to be able to advertise the absence of alcohol.

The Quarantine Investigation.

One of the most disheartening facts in this country is the way in which public officials are harried for purely personal, political, or business reasons. The attack on Dr. Wiley is an instance of the last named. The charges against Dr. Doty, health officer to the port of New York, of inefficiency and neglect of duty are an instance of political animosity that fortunately has failed. A leading article in a morning paper, usually in general sympathy with the attacking party, on August 24th spoke of the resulting investigation as "reassuring, bringing out clearly the efficiency, the comprehensive sense of responsibility, the adequate and enlightened and far-reaching methods of the man upon whom, more than upon all other instruments of protection, the country depends for safety from imported pestilence. How unwise and shameful is the warfare!" Citizens and visitors alike are pleased and reassured by the result of this investigation.

Abolition of Public Drinking Cups.

The Sanitary Code ordinance, which comes into force in New York on Oct. 1st, abolishes common drinking cups in public places, hotels, public schools, railway stations, and theatres. The large hotels will either serve water free on demand in the restaurant or bar, or provide maids to serve water from the hotel fountains in glasses to be carefully washed after each individual use. An ingenious penny-in-the-slot machine will solve the problem for the railway stations, and school children will be obliged to carry individual cups. Difficulties may arise in factories, as the law forbids the loan of a cup by the owner.

Imitation Health Board Inspectors.

Grocers and butchers in outlying boroughs of New York have been victimised by bogus inspectors from the health department, who in return for payment for supposed advertising space in an imaginary health publication, promised the tradesmen immunity from prosecution for violation of health ordinances regarding the protection of meat and fruit from street dust. It is difficult to sympathise with the victims, who were thus seeking to evade wise sanitary regulations, but the law protects even such rascals, and the impersonators will be dealt with severely when caught.

Sale of American Patent Medicines.

Patent medicines to the amount of £1,400,000 were exported from the United States last year. Cuba is the largest customer to the extent of £84,000, Canada coming next with purchases amounting to £67,000. China swallows some

£6000 worth of American patent medicine, and the Philippines about £24,000. It is not uninteresting to learn that aphrodisiacs, real or imaginary, command the largest sale in the tropics.

New Superintendent of Johns Hopkins Hospital.

The successor of Dr. Henry M. Hurd as superintendent of Johns Hopkins Hospital, Baltimore, is Dr. Winford H. Smith. He is a graduate of the medical school attached to the University, having taken his degree in arts at Bowdoin College, Maine. Dr. Smith has had much hospital experience in Cleveland, Ohio, in Hartford, Conn., and in New York, where for two years he was superintendent of Bellevue and the Allied Hospitals.

Death of a New York Physician.

Dr. Herman P. Bender, a physician in extensive practice in the borough of Brooklyn, was run over recently by a racing motor-car as he was alighting from a tramcar on his way home from a professional call and instantly killed.

Crowding of Tuberculosis Sanatoriums.

New York residents who may have been ordered by their physicians to go to a sanatorium for proper treatment of incipient tuberculosis have found it impossible to comply on account of the lack of room at these institutions; all are overcrowded and there are long lists of waiting applicants. Mr. Philip P. Jacobs, secretary of the National Association for the Study and Prevention of Tuberculosis, states that there are 30 000 cases registered in New York alone (out of a probable total of 50,000), while there are but 3000 beds in city institutions reserved for the tuberculous. Where a patient desires to pay, say, £2 a week, he finds it more difficult to obtain accommodation than the absolute pauper. There is a good opportunity for commercial enterprise, according to the secretary, to open sanatoriums where decent board and lodging might be furnished at £3 a week.

Unusual Resistance to Electric Current.

A negro convicted of wife murder was executed at Eddyville, Ky., on August 23rd. Although of frail build, the first application of a current of electricity of a voltage of 2500 caused him to burst the retaining straps and fall upon the floor unconscious. He was re-strapped in the chair and the current was passed through his body for 28 minutes before life was pronounced extinct.

Sept. 6th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Hospitals Bill for New South Wales.

THE Labour Government of New South Wales is taking an active interest in hospital questions. It proposes to remove the portion of the Sydney Hospital building that abuts on Macquarie-street and to build a new wing at the rear in what is known as the Domain. Mr. Flowers, the Chief Secretary, is submitting an extensive memorandum to the Cabinet covering hospital management in general. It is proposed to make pulmonary tuberculosis a notifiable disease and to provide homes and sanatoriums. The establishment of Lock hospitals will also be recommended, and the care of convalescents will be outlined. The memorandum will discuss the possibility of establishing (1) special fever hospitals; (2) cancer hospitals; (3) ophthalmic hospitals; (4) skin hospitals; and (5) epileptic hospitals. There are two State hospitals already in New South Wales, and the Sydney and Prince Alfred Hospitals are practically State institutions.

Curious Double Tragedy.

A fatality occurred recently in a medical ward at the Melbourne Hospital owing to a patient drinking by mistake a solution of carbolic acid instead of medicine. The patient suffered from goitre, and it was not clear that the poison was directly responsible, death being apparently from shock. The patient from the next bed, a girl aged 17 years, gave evidence at the inquest, and the following day drowned herself in the river without any apparent reason.

The Public Health Department in Victoria.

Extensive reorganisation of the Victorian Department of Public Health is in progress. Dr. A. A. Brown, superintendent of food for export, has been joined to it with his staff, and the criminal investigation analyst and his staff will also be under its direction. It is probable that before long the board will be reconstituted.

Federal Quarantine.

Dr. W. Ramsay Smith has resigned the office of Chief Health Officer for South Australia, and Dr. W. J. Gething will in future hold the appointment under the Federal Director of Quarantine. A new appointment of Superintendent of Quarantine for Victoria will also be filled shortly at a salary of £650 per annum. It is stated that Dr. B. H. Morris, the Director, will leave shortly for a six months' tour of inspection of the quarantine regulations and arrangements elsewhere.

The British Medical Association.

At the annual meeting of the South Australian branch on June 25th Dr. W. T. Hayward, the retiring President, moved the following resolution, which was carried:—

That in the opinion of this branch it is desirable that negotiations should be entered into with a view to the amendment of the constitution of the British Medical Association so far as the Australian branches are concerned.

Copies of this are to be sent to all sister branches in Australia, accompanied by a memorandum consisting of four paragraphs, the first two of which are as follows:—

1. There is no suggestion of any body separate and distinct from the British Medical Association, but only for autonomy on distinctly Australian matters. The fact that it was proposed by Dr. W. T. Hayward, one of the founders of this branch, should be sufficient guarantee of this. To use political terms, the ideal is for a federation of self-governing branches, whereas at present the branches are like Crown colonies negotiating through the Colonial Office.
2. Such autonomy is urgently required, in order that the profession may unitedly deal with questions of contract practice, hospital abuse, medical defence, &c., as outlined by Dr. G. E. Rennie's resolution carried at the Australasian Medical Congress held at Adelaide.

The suggestion will probably be favourably received in all the States, as it has long been felt that local self-government is requisite.

Health of Melbourne.

The annual report of the city health officer gives the population of the city (exclusive of the suburbs) as 100,000, with a death-rate of 12·4 per 1000 and a birth-rate of 22 per 1000. The infant mortality figure (115 per 1000) is appreciably higher than for the preceding nine years. Melbourne city has a typhoid fever mortality of 8 per 100,000, as against 4·4 in London. The death-rate from tuberculosis was 113 per 100,000, as against 266 during the period 1891–95. Food samples showed little or no adulteration; 194 of 213 samples of milk were up to the standard. The bacteriological report stated that the milk-supply as examined in the laboratory was more than four times purer in 1910 than in 1907. No sample was found to contain tubercle bacilli.

Coronation Honour.

The list of Coronation honours included the name of a well-known Melbourne medical man, Dr. J. W. Barrett, who received the Order of C.M G. Dr. Barrett's work in connexion with the Melbourne University council and his assistance in many philanthropic and artistic movements have been unsparingly rendered for a number of years. He is a graduate of the University of Melbourne, but was for some time a demonstrator of physiology at King's College, London.

Prevalence of Syphilis.

By the courtesy of Dr. J. W. Barrett an advanced copy of the report, presented to the Victorian Government, of the result of a year's impersonal investigation of syphilis in the metropolitan district of Melbourne, has been placed at my disposal. The report states that Dr. B. B. Ham induced the Government of Victoria to make provision for a collective investigation of the prevalence of the disease throughout the area in question by means of the Wassermann test. An advisory committee was formed, with Professor H. B. Allen as chairman, and Dr. Ham, Dr. Barrett, Dr. K. Hiller, and Dr. A. Jeffreys Wood. Dr. Ernest Jones being subsequently invited to join the committee, and circulars were issued to all medical practitioners within the metropolitan district inviting them to forward samples of blood from every case diagnosed as syphilis or open to suspicion of syphilis. A schedule was given not only of ordinary syphilitic manifestations, but of diseases and occurrences in adults, children, and infants, in the sane and the insane, in connexion with childbirth, &c., which, in the opinion of the

committee, should cause the test to be applied. The reports were to be impersonal, and a fee was paid for each report. Dr. Hiller performed all the tests, with assistance in collateral work in the later stages by Dr. H. Douglas Stephens. The response from the profession was very large, 5000 distinct cases being reported. In addition, Dr. Barrett during four months submitted to Dr. Hiller's testing every case attending his clinique at the Eye and Ear Hospital as in-patient or out-patient for any cause whatsoever. The main outcome of these investigations is as follows:—Out of 5000 cases reported (not including those of Dr. Barrett) 1900 gave a positive reaction, and over 400 a partial reaction. Experience has shown that out of 100 cases of syphilis, only about 60 will give a positive reaction; so that 60 positives represent 100 cases of syphilis. Therefore, 1900 positives represent 3167 cases of syphilis, or 63·3 per cent. out of the 5000 reported. On the metropolitan population of 600,000, this means that more than 0·5 per cent. were found to be syphilitic. The general figure for Melbourne is a multiple of the 0·5 per cent. found by Dr. Hiller, but exactness has not yet been attained. The gravity of the matter is beyond question, though there is no reason to suppose that Melbourne is in worse case than other large cities, and the advisory committee is convinced that the investigation must be continued. The collective investigation so conducted is the most extensive and important accurate research into the prevalence of syphilis that has yet been conducted in any part of the world.

August 12th.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Gratz:* Dr. Josef Schaffer of Vienna has been offered the chair of Histology.—*Innsbruck:* Dr. Franz Ballner, *privat-docent* of Hygiene, has been granted the title of Extraordinary Professor.—*Munich:* Dr. Süpfler of Freiburg has been recognised as *privat-docent* of Hygiene and Bacteriology.—*Palermo:* Dr. Nicola Pende of Rome has been recognised as *privat-docent* of Internal Pathology.—*Parma:* Dr. Roberto Pignatari has been recognised as *privat-docent* of Ophthalmology.—*Prague:* Dr. F. Samberger, *privat-docent* of Dermatology, and Dr. J. Cisler, *privat-docent* of Laryngology, have been granted the title of Extraordinary Professor.—*Rome:* Dr. Pietro Imbriaco of Florence has been recognised as *privat-docent* of Operative Medicine.—*St. Petersburg (Military Medical Academy):* Dr. D. D. Popoff has been appointed to the chair of Midwifery and Gynæcology in succession to Dr. Lêbêdeff. *Sienna:* Dr. Bernadino Lunghetti of Bologna has been recognised as *privat-docent* of Anatomy.—*Turin:* Dr. Giovanni Giuseppe Guyot-Bourg of Geneva has been recognised as *privat docent* of Internal Pathology.—*Vienna:* Dr. Rudolf Loos, *privat-docent* of Odontology, and Dr. Moritz Sachs, *privat-docent* of Ophthalmology, have been granted the title of Extraordinary Professor.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.—The vacation session of practical classes commences on Monday next, Sept. 18th, and extends over three weeks. The following are the teaching staff on the various subjects:—Mr. J. D. Mortimer (Anæsthetics), Dr. C. O. Hawthorne (Clinical Examination of the Nervous System), Dr. J. E. Squire (Clinical Methods and Physical Diagnosis), Dr. J. Campbell McClure (Clinical Examination of Gastric Contents), Dr. F. W. Price (Clinical Studies of the Heart by the Newer Methods, including the Polygraph), Mr. J. Swift Joly (Cystoscopy), Mr. J. M. Flavelle (Electro-Therapeutics and Diagnosis), Dr. F. J. McCann (Gynæcology), Mr. J. Jackson Clarke (Intestinal Surgery), Mr. J. Gay French (Laryngology), Dr. J. Fletcher Little (Massage and Medical Electricity), Dr. R. E. Bickerton (Ophthalmology), Mr. Laming Evans (Orthopædics), Dr. Dan McKenzie (Otology), Mr. W. Stuart-Low (Rhinology), Dr. F. Harrison Low (Roentgen Rays), Mr. P. Maynard Heath (Sigmoidoscopy), and Mr. J. M. G. Swainson (Surgical Anatomy and Diagnosis). The composition fee for certain of the classes and the separate fees for each class and for the tutorial classes directed at the higher examinations can be obtained, together with information as to the days and hours on which the classes meet, from the Medical Superintendent, the Polyclinic, 22, Chenies-street, Gower-street, London, W.C. Private tuition is also offered in the ophthalmoscope, laryngoscope, otoscope, cystoscope, sigmoidoscope, sphygmograph, sphygmomanometer, &c.

THE judges appointed to examine and report on the exhibits at the Festival of Empire have awarded to Messrs. Newton, Chambers, and Co., Limited, a Grand Prix for their Izal disinfectant preparations.

A DENTAL SCHOOL FOR LONDON HOSPITAL.—A quarterly court of the governors of this hospital was held on Sept. 6th, Mr. G. E. Maurice presiding, when a vote of sympathy was passed with the relatives of Mr. John Hampton Hale, who had been chairman of the institution. At this meeting a committee reported that the governors had approved of a dental school at the hospital.

NEW HOSPITAL FOR AXMINSTER (DEVON).—The foundation-stone of the new Axminster Cottage Hospital was formally laid on Sept. 6th by Mr. R. Cornish, the president of the hospital, in the presence of a large gathering. The old hospital, founded in 1866, has for some time been found to be inadequate for modern requirements, and the inhabitants of Axminster decided to erect a new institution "in memory of His Majesty King Edward VII., and to celebrate the Coronation of King George V." The cost of the new building will be about £2000.

DEVON AND CORNWALL EAR AND THROAT HOSPITAL, PLYMOUTH.—The committee of this hospital has issued an appeal for funds for erecting new buildings for the charity. The hospital has been established about 25 years, and for some time it has been apparent that larger premises must be provided. A scheme has been prepared, at an estimated expenditure of £2000. The Charity Commissioners have sanctioned the sale of stocks representing legacies valued at £1214 towards the cost of the undertaking, and consequently about £800 still remain to be obtained, and this sum, it is hoped, will shortly be raised as a result of the appeal.

CONSUMPTION AND SANATORIUMS IN CANADA.—According to a paper published by Dr. C. D. Parfitt in the August *Dominion Medical Monthly*, Canada now possesses 20 or more sanatoriums and special hospitals for the treatment of cases of tuberculosis of the lungs. This is the outgrowth of 14 years. Twelve of these are in the Province of Ontario, with 547 beds, and during the past year 1421 patients were treated. It is estimated that the actual number of patients alone with tuberculosis in Ontario is 10,000, and that 171,000 of those now living in the province will die from tuberculosis, according to the present death-rate, at the rate of 2500 yearly.

DONATIONS AND BEQUESTS.—Under the will of the late Mr. J. T. Johnson, the Birmingham General Hospital, the Queen's Hospital, Birmingham, the West Bromwich Hospital, and the Walsall Cottage Hospital will each receive £1000.—Mrs. S. Pierce has bequeathed by her will £1000 to the Manchester Royal Infirmary, £500 each to the Manchester Hospital for Consumption, the Manchester Hospital for Cancer, and the Crippled Children's Help Society, and £250 each to the Royal Society for the Prevention of Cruelty to Animals and the National Society for the Prevention of Cruelty to Children.—Mr. Abraham Greenwood Eastwood left £1000 to the Royal Halifax Infirmary to endow a bed in the children's ward.—The late Mr. J. E. Yonge of Brixton has bequeathed £500 to the South Devon and East Cornwall Hospital, Plymouth, and £250 each to the Plymouth Public Dispensary; Royal Eye Infirmary, Plymouth; St. Elizabeth's Convalescent Home, Plympton; and the Ear and Throat Hospital, Plymouth.—The late Dr. Samuel Jones Gee has left the residue of his property, amounting to about £20,000, to his daughter for life, with contingent remainder to the Royal College of Physicians of London, upon trust as far as possible to form a permanent endowment fund for the College.—The late Mr. Johann Jacob Michael Hermann Spies has bequeathed the

ultimate residue of his property, amounting to about £6000, with contingent remainder equally between the Hospital for Women, Soho-square, the National Hospital for Diseases of the Heart, Soho-square, the London Hospital, the German Hospital, the North Wimbledon Cottage Hospital, the South Wimbledon Cottage Hospital, the London Orphan Asylum, Watford, the Infant Orphan Asylum, Wanstead, and the Society for Granting Annuities to the Poor Adult Blind.

Births, Marriages, and Deaths.

BIRTHS.

CUNNINGHAM.—On Sept. 11th, at Sussex-place, Regent's Park, the wife of J. F. Cunningham, F.R.C.S., of a daughter.

PENROSE.—On Sept. 11th, at West Bar, Banbury, to Dr. and Mrs. N. C. Penrose—a daughter.

WOLSELEY-LEWIS.—On Sept. 8th, at Maidstone, Kent, the wife of H. Wolseley-Lewis, M.D., F.R.C.S., of a son.

MARRIAGES.

GORDON—BANCROFT.—On Sept. 6th, at St. Mary's Church, Tenby Francis Jervis Gordon, B.A. Cantab., M.R.C.S., L.R.C.P., to Frances Gwendolen, elder daughter of John Bancroft, M.A. Oxon., H.M.I.S.

SALISBURY—MURRAY-WHITE.—On Sept. 11th, at Holy Trinity Church, Murree, Punjab, Francis Hugh Salisbury, Captain, I.M.S., to Ivy, fourth daughter of the late Captain Samuel Murray-White, of the 1st Wilts Regiment.

WALLACE—AYRES.—On Sept. 6th, at St. Barnabas, Kensington, Frederick Wallace, L.R.C.P. Lond., to Caroline Rebecca, elder daughter of the late G. S. Ayres.

DEATHS.

HATTON.—On Sept. 2nd, at Carlsbad, Piers James Hatton, M.B., aged 46 years.

PETTIFER.—On August 23rd, at Weymouth, Edmund Henry Pettifer, M.R.C.S., late of 32, Newington-green, London, aged 83. R.I.P.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE CROSS-CHANNEL SWIM.

MANY attempts to swim across the English Channel have been made since the late Captain Matthew Webb first accomplished this great feat in August, 1875, but they have all been unsuccessful until on Sept. 6th Mr. Thomas William Burgess repeated Captain Webb's exploit. We reported Captain Webb's great feat of endurance, and now record that of Mr. Burgess, although our readers will probably have all read the details in the daily press. Burgess entered the water at 11.15 A.M. on Sept. 5th, to the east of Dover at a point between the South Foreland Lighthouse and St. Margaret's Bay. The wind was blowing fresh from the north-east and the water was somewhat rough. The tide was at the time flowing eastwardly and carried him in a northward and eastward direction, so that after an hour and a quarter's swimming he was near the South Goodwin Lightship, 3½ miles from the shore, and in three hours he was six miles from the shore east of his starting point. The tide now turned and carried him in a southwesterly direction until, after he had been seven hours in the water, he was three miles south of the Varne Buoy, which lies between Folkestone and Cape Grisnez. On entering the water he had been rubbed all over with lard, and as a protection against the waves and the sun's rays he wore a pair of motor goggles and an indiarubber cap. After being in the water for an hour and a half he drank some hot chocolate, and after four hours he suffered from uneasy sensations, but on approaching the Varne Buoy he felt better, and there was a complete calm on the water towards sunset. Through the ensuing night, which was in every way favourable to him, being very fine and quite calm, he took hot milk, chocolate, and grapes at frequent intervals. From the neighbourhood of the Varne Buoy the second change of tide during his swim carried him in a northerly and easterly direction, until at dawn on Sept. 6th Cape Grisnez bore south-west and Calais south-east. He had now been swimming for about 18 hours, and during the next four hours he had several attacks of weakness and muscular cramp in the left side of the chest, attributed by himself to his use of the over-arm stroke with his left arm, a stroke which he kept up for more than 15 hours at a rate of 24 to the minute. The third turn of the tide during his swim found him about ten miles off Calais and drifted him in a south-westerly direction towards Cape Grisnez, from which he was about a mile distant at 7 A.M.; another turn of the tide was then nearly due, and for a time there was some anxiety lest he might be carried past the cape without being able to land; he was, in fact, carried past it at a distance of 400 yards from the shore, but by a great effort he landed about a mile eastward of Cape Grisnez, near the village of Chatelet. He walked ashore at 9.50 A.M. on Sept. 6th, after having swum for 22 hours and 35 minutes. Burgess is a big man about six feet in height and 40 years of age, and his feat is a wonderful proof of the strength and endurance of the human frame.

HEALTH REPORT OF THE BAHAMAS.

A CENSUS of the Bahama Islands, taken on April 2nd, 1911, gave a total of 55,872 souls, as against 52,735 in 1901. The births in 1910 numbered 2129 and the deaths 1457; birth-rate 3·4 per cent., death-rate 2·3 per cent. According to the report of the acting medical inspector, quoted in the Blue-book of the colony for the year ended March 31st, 1911, the general health has been good. During the autumn and winter months influenza existed in an epidemic form in New Providence district, and on some of the outer islands its propagation has probably been greatly facilitated by means of the dust consequent on a prolonged drought. While many of the cases have been of a severe nature, comparatively few deaths have occurred. There were a few cases of typhoid fever, with two deaths. During the early part of the year a case of small-pox was landed in the colony from Mexico, but prompt measures of isolation and disinfection prevented the occurrence of secondary cases. A few cases of typhus fever were introduced into Ragged Island, but the disease did not spread. The street drainage of Nassau is still in an unsatisfactory condition, but such measures as the finances of the colony justified have been carried out for its improvement. The rainfall (25·71 inches) was unusually low, but the supply of spring-water has been plentiful and good. 622 vaccinations were successfully performed in New Providence, and 1637 on the out-island settlements.

The Bahamas General Hospital, formerly known as the New Providence Asylum, was established in 1809 as a poor-house and hospital for the poor and infirm of the island. Since then the institution has grown steadily, and its functions have been extended in many directions. In 1845 it was placed under a board of commissioners appointed by the Governor, and now comprises the hospital proper, the infirmary, dispensary, lunatic asylum, and leper compound. During the year 718 patients were under treatment, of whom 234 were discharged recovered, 99 relieved, 30 discharged not improved, and 124 died. Every year many cases are received in a hopeless—often moribund—condition. The assistant surgeon visited 1082 cases at their homes. It is probable that the accommodation for lepers (of whom there were eight in the asylum at the end of the year) will in the near future have to be enlarged and improved in view of the compulsory segregation which is under consideration.

The Colonial Secretary's report refers to a movement for the union of the colony with Canada, and suggests that one of the results of the agitation will no doubt be the influx next year of many more Canadian visitors than hitherto, and this "will at least have the effect of giving the colony a free advertisement and of drawing the attention of the public to the great advantages possessed by Nassau as a salubrious winter resort."

HEALTH AND SANITATION IN THE FALKLAND ISLANDS.

A REPORT on the Blue-book of this colony for the year 1910, prepared by Mr. W. A. Thompson, has been received at the Colonial Office. It states, *inter alia*, that the birth-rate for the year was 18·92 per 1000, as compared with 23·08 in 1909, whilst the death-rate was 6·72 per 1000 as against 8·60 in 1909; but it is pointed out that these figures are misleading unless one remembers that the population of the islands is an exceptional one owing to the immigration of young men, who frequently leave the colony when past middle age. Males are greatly in excess of females, the proportion being as much as 3 to 2. No death occurred of persons between the ages of 8 months and 40 years. The rate of infant mortality compares very favourably with that of England, and bears witness to the care which mothers in the islands devote to their offspring. The health of the colony has, with the exception of an epidemic of scarlet fever and influenza, been satisfactory throughout the year. In July influenza attacked at least 50 per cent. of the inhabitants of Port Stanley—the only important settlement. The disease was apparently imported from Buenos Aires, where it was prevalent. The earlier cases were liable to lung complications, and convalescence, as usual in this complaint, was very protracted. Towards the end of the year there was a marked recrudescence of the disease, when in most cases the digestive organs were affected, with severe vomiting and diarrhœa. The Falkland Islands, with their damp, cold climate, will be very liable to this disease.

The Colonial Surgeon (Dr. R. S. Earl) writes: "In spite of the force of the strong prevailing wind, which usually arouses into fatal activity the hitherto dormant tubercle bacillus, it is interesting to note that although diseases of the respiratory system, especially bronchitis, are prevalent here, phthisis and other forms of human tuberculosis are fortunately absent. I have only seen two cases during the 18 months I have been here, and in one of these the disease was contracted in Patagonia. This fact is the more striking as the disease is found in sheep here. Pharyngitis was, as usual, prevalent, and some cases of acute tonsillitis were seen. ..... There can be no doubt that the health of the people in Stanley would benefit if the consumption of alcohol was diminished. In the absence of statistics one does not wish to insist too strongly on personal impression, but I should be surprised if the amount of alcohol consumed per head by the population here is not found to be largely in excess of the average quantity used per head in an English seaport town."

"THE SEASONED TOBACCO PIPE."

IN an annotation under the above heading in our columns of June 3rd we referred to a singular instance of tobacco poisoning due to the use of an old seasoned pipe. It is an axiom amongst smokers that "An old pipe smokes best," but that a pipe well saturated with tobacco-distillation products can be a source of injury to the health of the consumer seems to have been established in the case referred to. Mr. W. H. Yearon, of Messrs. Grant and Co., Ltd., of Riley-street Tower Bridge, London, S.E., suggests, as a means of obviating such a mishap, an aluminium thimble placed in the bowl. To a large extent by this device the tarry oils are prevented, at all events, from entering the bowl and the pipe keeps clean. It is not certain, however, whether the oils do not accumulate in the stem and nearer the mouth of the smoker. We are inclined to think that when special precautions, in the shape of absorbers, condensers, and what not, appeal to a smoker as making smoking a safer habit he had better eschew tobacco altogether.

THE "UNKNOWN TONGUES."

AN old copy of the *Morning Herald* of Oct. 31st, 1831, has just come into our hands, which affords a curiously vivid and matter-of-fact glimpse of the phenomena known in their time as the "Unknown Tongues." These tongues were doubtless the ramblings of victims of imitative mania who were suffering from the over-excitement and mental fatigue caused by the fervid three-hour discourses of Edward Irving, the Scottish divine, whose life and achievements are familiar to many of us, especially to readers of Carlyle. Irving in 1828 had removed from a small and overcrowded chapel in Hatton-garden, London, to a more commodious one in Regent-square, and here on Oct. 16th, 1831, "the public services were interrupted by an outbreak of unintelligible discourse from a female worshipper." Our quotation is from Dr. Richard Garnett's life of Irving. These outbreaks became frequent, and on Oct. 30th, 1831, the church in Regent-square was crammed during morning service. Before beginning his sermon Irving explained his position. "I dare not—I say it is not a matter of option"—he declared, "I dare not for my life prevent the manifestations." Later he was interrupted by a man crying in a loud voice—"God's supporting me. I am ready to be crucified for the true God, but not for the Devil." These and other remarks led Irving to protest and to explain—"All persons who speak in the tongues are known to me; all others are but brawlers." In common with more modern illuminati, he sought to speak of the "unknown tongues" in terms at once rationalistic and critical. He reminds us, indeed, of certain psychical researchers labouring to appear sternly scientific. "If a foreigner," said he, "ignorant of the English language, were now present and he should see me full of action, and my countenance full of intelligence, and if he were to say, because he did not understand me, that what I am now uttering is nothing but gibberish, that would be beyond all things uncharitable. It is not only uncharitable, but the greatest and most grievous sin to deny that it is the work of inspiration."

The earliest speaker of the unknown tongues, a Miss Mary Campbell, who may have been influenced by a perusal of the old travels of George Keate and Captain Henry Wilson, believed that the tongues were the language of the Pelew Islanders, who are Shamanites of Samoan origin in the Caroline Island group (Western Pacific). Irving himself protested that they were "regularly formed, well-proportioned, deeply-felt discourse, which evidently wanteth only the ear of him whose native tongue it is to make it a very masterpiece of powerful speech."

There are, it appears, ancient Greek elements in the following hymn which appeared in the pamphlet of one M'Kerrell, who wrote when the number of the gifted was 15:—

"Hippo gerosto niparos,
Boorastin farimi:
O Fastos Sungor boorinos,
Epoongos menati.
O Deripangito boorin;
Aristos ekrampos
Senoote hypanos noostin,
Hypen hippo booros."

THE TREATMENT OF OBSTINATE PSORIASIS.

To the Editor of THE LANCET.

SIR,—I have a patient who has suffered from psoriasis for 25 years. That on the trunk and limbs answers fairly well to treatment, but on the scalp the condition is intractable. From the daily application of ointment or lotion my patient's life is anything but a happy one. I would be very grateful for any suggestions from your readers as regards treatment. I have tried all the usual remedies without success.

I am, Sir, yours faithfully,

Sept. 12th, 1911. BEATEN.

Hendiadys.—The revolting belief is still common in spite of the spread of education. It need not be said that there exists in medical literature no authentic case of such an occurrence; it would be a physiological impossibility. Popular chap-books detailing the stories of Mary Tofts, of pig-faced ladies, and so on, have popularised a credulity that always existed.

Altruist.—1. The idea is rubbish. 2. See THE LANCET, vol. i., 1897, pp. 368 and 433. 3. Our correspondent is recommended to obtain the name of the tree and communicate personally with the officials in question.

One in Doubt.—The symptom is produced by so many conditions that no one method of treatment can possibly be efficacious. We will consider the suggestion that it might be wise to discuss the matter publicly.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for September, 1911:—

April–October.—Rome Exhibition (United Italy's Jubilee).
,, 29th–Oct. 26th (Turin).—International Exhibition.
May 3rd–Oct. 31st (Glasgow).—Scottish Exhibition.
,, 6th–Oct. 31st (Dresden).—International Hygiene Exhibition (British Section opens June 14th).
May 12th–Oct. 31st (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
May 18th–October 31st (London, Shepherd's Bush).—Coronation Exhibition.
,, 19th–Oct. 31st (London).—Earl's Court Exhibition.
Sept. 16th–23rd (London, Agricultural Hall).—Nineteenth Annual Grocery Exhibition and Market.
,, 17th–20th (Turin).—Second National Congress of Guardians of Training Schools and Prisons.
,, 18th–23rd (Sydney).—Australasian Medical Congress.
,, 18th–23rd (Paris).—International Conference of Genetics.
,, 23rd–Oct. 21st (London, Olympia).—Electrical Exhibition.
,, 24th–30th (Karlsruhe).—Eighty-third Meeting of German Physicists and Physicians.
,, 25th–26th (Munich).—Meeting of the International League for Medical Psychology and Psychotherapy.
,, 26th–28th (Louisville, Ky.).—American Association of Obstetricians and Gynecologists.
,, 26th–30th (Brussels).—Third Congress of the International Society of Surgery and Exhibition of Fractures.
,, 28th and 29th (Manchester).—Conference of British Hospitals Association.
,, 28th–30th (Dresden).—International Congress for the Protection of Mothers and Sexual Reform.
,, 29th (Edinburgh).—Association of Veterinary Officers of Health. Annual Meeting.
,, 30th (Bruges).—Sixth Belgian Congress of Neurology and Psychiatry.
September (Genoa).—International Exhibition of Marine Hygiene.
,, (Turin).—Congress of the Association of Italian Railway Physicians.
September–November (Antwerp).—International Exhibition of Alimentation, Brewing, Wines, and Liqueurs.

Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. Graham Little: Clinique (Skin).
TUESDAY.—4 P.M., Dr. C. O. Hawthorne: Clinique (Medical).
WEDNESDAY.—4 P.M., Mr. Gordon Taylor: Clinique (Surgical).
THURSDAY.—4 P.M., Mr. H. Lett: Clinique (Surgical).
FRIDAY.—4 P.M., Dr. Dan McKenzie: Clinique (Ear, Nose & Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. Bishop Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women.
THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. Bishop Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON), Clinical Theatre, London Hospital, Mile End-road, E.

MONDAY.—2 P.M., Demonstration in Clinical Medicine:—Dr. Wall: Pulmonary Diseases.
TUESDAY.—2 P.M., Demonstration in Clinical Medicine:—Dr. Grünbaum: Diseases giving rise to Morbid Renal Excretion.
THURSDAY.—2 P.M., Demonstration in Clinical Medicine:—Dr. Head: Diseases of the Nervous System.
FRIDAY.—2 P.M., Demonstration in Clinical Medicine:—Dr. L. Smith: Diseases of the Heart.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (18th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.). Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.) Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (20th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's 2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (21st).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (22nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas s (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.)., Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (23rd).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1911, which was completed with the issue of June 24th, were given in THE LANCET of July 1st.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1911 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Sole Agents for Advertising in Germany, Austria, Hungary, Switzerland, and the French and Italian Riviera—RUDOLF MOSSE, Berlin. S W., and all Branches.

Agent for the Advertisement Department in France—J. ASTIER, 35, Rue Franklin, Asnières, Paris.

A Clinical Lecture

ON

TWO CASES OF EXTENSIVE EXCISION OF THE COLON AND ILEUM FOR TUBERCULOUS DISEASE,

WITH SOME DETAILS OF TECHNIQUE.

By ARTHUR E. BARKER, F.R.C.S. Eng.,

SURGEON TO UNIVERSITY COLLEGE HOSPITAL, LONDON; AND CONSULTING SURGEON TO THE QUEEN ALEXANDRA MILITARY HOSPITAL, MILLBANK, S.W.

GENTLEMEN,—The removal of long tracts of the large intestine for malignant and other disease such as tubercle and actinomycosis is now a common operation and one giving excellent results, immediate and remote. And with the improved means of diagnosis which are almost daily being devised the procedure is certain to become more frequent and beneficial. But such operations are only justifiable when undertaken by those who fully realise their difficulties and dangers and who have studied their technique in every detail. So many minutiæ in manipulation as well as principles have to be kept in mind all through these long operations that only careful training amounting almost to habit will prevent some of them being overlooked. I venture to think that a few notes on the technique of these procedures gradually evolved in my own work, which includes numbers of cases dealt with in various ways, may be of use to others confronted by the inevitable difficulties inherent in such procedures. And from many inquiries which have reached me on the subject I gather that it has not yet been adequately discussed. As regards the diagnosis of the essential tumours of the large intestine, there is a general feeling that this is not as closely studied as is called for, and in the February number of the *Practitioner* I tried to help in this direction. And in the matter of getting at, and of the adequate and safe removal of, different parts of the large intestine for disease we need all the personal experiences which can be accumulated. It must not be forgotten that this branch of intestinal surgery is almost exclusively the growth of the last 10 or 12 years, before which time little was seen of it. Consequently much that may now be known to individual operators is not yet common property.

ABDOMINAL INCISION.

On the point of access to the various parts of the large intestine it may be said that with the exception of the central third of the transverse colon, for which a median incision is suitable, all other segments may best be reached through an oblique flank incision on either side. This not only gives as free a field as can be obtained by any reasonable opening, but also does so with a minimum of injury to the muscles, nerves, vessels, and fasciæ of the abdominal wall. As the skin adds but little to the actual strength of the parietes it can be freely incised, and should be so especially in obese people. The cut in the skin should begin near the end of the tenth or eleventh rib and run downward and forwards nearly to the mid-line between the umbilicus and symphysis pubis. When the external oblique aponeurosis is exposed its fibres should be separated rather than cut, and the same may be said of the two deeper muscles. It is surprising what a wide opening can be obtained in this manner without actually dividing the fibres of the muscles in question. The nerves which supply the rectus, the oblique, and the transversalis muscles are also preserved intact with a little care and very few vessels are cut. The innervation and blood-supply of the abdominal wall are by these means preserved and its future strength is unimpaired. If the opening is not large enough when it reaches the sheath of the rectus this may be opened and the belly of the muscle be drawn inwards without difficulty, still further enlarging the aperture. At this stage the aim should be to gain adequate room without spoiling the abdominal wall. Vertical incisions *outside* the rectus sheath are unsuitable in these cases, the tissues, owing to the direction of their fibres, giving but little hold for any form of subsequent stitching and tearing apart easily if there be any vomiting or coughing. Besides this, the nerves and vessels must be cut by such incisions, as they run downwards and inwards.

THE LOCAL AND GENERAL CONDITION.

Assuming now that on opening the peritoneum in the line described it be found, as was the case in my two last cases, now convalescent, that the upper part of the ascending colon, as well as the cæcum, are extensively involved and call for removal, what is the next step? This is largely determined by the local condition and the patient's strength. If it be found that the diseased area is sufficiently localised to justify an attempt to remove it at one sitting, this may be set about at once *provided there is no extreme obstruction* and that the last part of the ileum is normal or hypertrophied, but is otherwise healthy. On the other hand, if the ileum is found paresed, distended, and congested, and loaded with liquid fæces, no attempt at extirpation should be made at the moment. Suture of a bowel, paralysed, livid, and soaked with toxins, is almost certain to end in failure of union at the point of suture of the intestine, even if it can be accomplished without the escape at the moment of some of the acrid fæces or foul mucus. A careful distinction must therefore always be made between the thickening of the ileum owing to compensatory hypertrophy and that due to œdema from toxins absorbed from fermenting foul fæces. In the first case the bowel will probably be of normal colour and texture and not much enlarged; in the latter its lumen will be much increased and it will be œdematous, injected, or even livid and softened. If it be in this condition a loop should be drawn out of the inner angle of the wound and the latter closed completely around it. If the patient's general condition permits, this loop should not be opened for some days, when it may be incised, and a Paul's tube inserted for drainage, which must be kept up until the whole small intestine has been emptied and the bowel has returned to a healthy condition. This is accelerated, I think, by the administration of bismuth carbonate in 10-grain doses three times daily. Of the antiseptic value of bismuth in intestinal cases, as in others, I have no doubt from large experience; indeed, it is my routine to employ it. When the colour of the motions coming from the fæcal fistula has been continuously altered by the drug, and they have become otherwise normal, we may begin to prepare for the excision of the diseased portion of bowel. In cases of subacute or chronic obstruction where operation is not urgently demanded I believe also that the daily use of bismuth carbonate greatly improves the chances of asepsis during the subsequent removal of the growth. It is taken for granted that every expedient is employed at the same time to unload the bowels. But such attempts should cease at least a couple of days before the operation.

ONE SITTING, OR TWO?

When there is no acute or subacute obstruction the problem is fairly simple, as we are going to work on healthy bowel more or less empty. But we have yet to decide whether to do the operation in two stages or at one sitting; in other words, should a short circuit between ileum and colon be first made and then, after an interval of two or three weeks, the excision of the diseased bowel be undertaken, or should the latter follow *at once* on completion of the anastomosis of the bowel above and below the part to be removed? As a matter of fact, I have accomplished the end in view in both ways many times over quite successfully. On general grounds, if a patient is in fair condition, the procedure in one sitting is much to be preferred. The relief to the sufferer's mind of having the whole affair over at once is great, and, conversely, the apprehension of a second operation after the first is often very depressing and a prospect which all will not face. Nevertheless, the amount of time which is required for the double procedure, junction and excision, which will be on an average two hours (my last required one and three-quarter hours), is a matter of gravity which cannot be overlooked in view of the anæsthetic and the prolonged exposure and manipulation of the viscera. I have been amazed, however, in several cases to see how little ill-effects have been produced by the double operation at one sitting even when of the longest. My last case had little or no shock; another earlier one in which the condition was complicated by a fæcal fistula in the cæcum, and which lasted two and a quarter hours, showed absolutely no ill effect from the prolonged operation, and is now, after

more than two years, in splendid condition. Personally I am inclined to rely for guidance on this point on the following factors. If there are no signs of toxæmia and the bowels to be anastomosed are healthy; if there are no wide-reaching adhesions, and the patient's general condition is good when the short circuit has been accomplished in a reasonable time, the excision should immediately follow. Cases of marked toxæmia with distended proximal bowel are, of course, excluded; they must be treated, as already stated, by artificial anus and evacuation for a time. In many cases of less distended bowel and only slight evidence of absorption of toxins it is better also to make two stages of the procedure—that is, if it should be undertaken at all without previous drainage by artificial anus. Towards the completion of the short circuit, then, the patient's general condition should be carefully considered by surgeon and anæsthetist, and if satisfactory the immediate excision may follow.

DETAILS OF PROCEDURE.

There are several details in the performance of the junction of the small intestine proximal with the large distal to the diseased area which are of special importance. The point to be selected in each comes first. In the proximal *healthy* small bowel the lower down the junction is made the better. In the first place general nutrition is less deranged, and in the second there is less mesentery to be taken away, time and blood being thus saved. In the case of the colon there should always be a wide interval between the diseased portion (whether cancerous or tubercular) and the spot distal to it selected for the junction with the ileum. This view is based upon the known wide distribution of the disease along the submucous lymphatics proximal and distal to the infected part so admirably demonstrated by Handley and so often hitherto the cause of recurrence in our older cases. There should be no hesitation in selecting a spot in the colon 6 or 8 inches or more beyond the palpable and visible infiltration. Any closer will in many cases, at all events, fall within the area of infection.

TECHNIQUE.

When the spot for junction has been selected each part of the bowel is drawn out and emptied by pressure with the fingers. Then they are clamped longitudinally, either singly or, if possible, side to side with a Doyen's forceps. (N.B.—The blades of these instruments are often made too powerful by many manufacturers, and if so may injure the bowel.) Every part of the wound and between and around the coils and clamps should now be packed with one *continuous* long strip of sterile gauze from an uncut roll. Then the two coils are united for at least 2½ inches longitudinally at about a third of an inch from the middle of one of the tæniæ, a long "tail thread" being left at the end opposite to the needle. The latter and its thread are then covered for the present by a turn of the gauze roll to preserve it from contamination later. The thread I have employed for the whole procedure for many years is of fine linen. (Barber of Lisburn, Ireland, is the spinner of this material for Singer's sewing machines; No. 90 is the strength used.) This suture is carried by an ordinary sewing needle. The "side threading" pattern, 2 inches long, is the most convenient. It is now stocked by Meyer and Meltzer, of 71, Great Portland-street, W. The sero-muscular union being now half made the opening in one bowel is cut, for 2 inches or so, through the tænia in the case of the colon. This is best done with scissors, and the length of the hole should be the same as that subsequently made in the other. Great care is necessary in making these openings to avoid soiling the wound with the contents of the bowel. This is always a most anxious part of the operation, for, in spite of the emptying of the gut before clamping, there is always at least infected mucus within it. This is best removed with small rolls of gauze held in forceps, fresh material and instruments being used each time. Then the opening in the other coil is similarly made and cleansed. It, too, should be about one-third of an inch from the sero-muscular suture previously half made. Personally I have an objection to using any lotion or even sterile saline at this stage lest any of the fluid mixed with fæces or mucus should run down over the edges on to the intestine; dry gauze is certainly cleaner. This is a far more serious matter than the cleansing of a gastro-enterostomy junction, but can be accomplished with practice as results show.

A second needle with the same sized (No. 90, Barber's scale) thread is now taken, and at the opposite end at which the first sero-muscular suture was begun is made to transfix all the coats of both bowels at about one-eighth of an inch from their edges and is tied, leaving a long "tail thread." From this point the needle and thread are carried over the cut edges of both bowels and again passed through all their coats about a quarter of an inch from the first, and so on until the two edges are united from end to end by a continuous overcasting suture. Then the corner is turned, the greatest care being taken that the serous edges are accurately coapted without the intervention of any mucous membrane. When this continuous suture has thus brought opening to opening all round the suture is completed by tying the "needle thread" to the "tail thread" at the point of departure. Then the whole line of suture is carefully wiped clean of any mucus which may have been squeezed out. Wet swabs are undesirable except in special cases. The sero-muscular suture is now completed with the needle and thread which has been covered from contamination during the "all coat" suture. The whole area involved in the junction should now be carefully wiped front and back after release of the clamps and all traces of blood removed. The long continuous strip of gauze is now taken away, and being in one piece there is no danger of any of it being left behind in the abdomen. Round the anastomosis it is now well to wrap a fold of omentum and secure it with a few interrupted sutures.

By this time it ought to be apparent to both surgeon and anæsthetist whether the patient's condition is such as to justify the much longer and more severe operation of extirpation of the segment of bowel including the disease. But it is a nice question to decide, and on the whole it is better to err upon the safe side and to divide the procedures into two operations than to make too great a claim upon the patient's endurance at one sitting. The judgment even of the experienced operator will, of course, be at fault occasionally; nevertheless, experience will tell almost as much as skill. The advantage to the patient of getting over the whole undertaking at once is so very great, however, that some risk may be taken. Feeling thus, my own preference in making the preliminary ileo-colostomy in the majority of cases is for a "side-to-side" anastomosis which reduces the chances of infection from the bowel. In it there are no turned-in stumps of intestine left about which we need be anxious and the procedure is shorter. But where on careful exploration of the growth and its surroundings in a patient in good general condition an extirpation in one sitting seems justifiable, there can be no doubt that to join the end of the divided ileum to a slit in the side of the colon is the quickest and safest procedure. Here there is no blind stump of ileum left in the abdomen, the stitching of which would have prolonged the operation and increased the risks of infection. There is, of course, the divided stump of the ileum in the part to be taken away. But this will be securely clamped, wrapped in gauze, and immediately lifted out of the abdomen and further enveloped in sterile towels out of the way of contact with anything which could infect the peritoneum or the wound in the abdominal wall. This "end-to-side" ileocolostomy is commenced by a sero-muscular suture between the undivided ileum and colon, which includes half the circumference of the opening. Then the ileum is clamped with two pairs of Doyen's clamps, the first close against the line of suture just made and the next half an inch below the first. Between the two the ileum is cut across as close to the first pair as possible. Then the cut surface of the partly sutured ileum is wiped clean and covered with gauze for the present, the clamp on it being removed. The other end with the clamp still firm is wrapped in gauze, and the mesentery belonging to it is divided between ligatures until the bowel can be well drawn out of the abdomen and wrapped in sterile towels for the present. The gauze is now removed from the partly sutured end of the ileum, its open end again cleansed, and a corresponding opening is made in the colon through one of the tæniæ, the edge of the cut being about one-third of an inch from the previously made sero-muscular suture line. Then the "all coat" suture is made uniting the two corresponding openings between ileum and colon as previously described. When all round has been wiped clean the sero-muscular suture is completed and tied to its tail thread. In cutting across the ileum care should be taken to remove more of the free

margin than of that attached to the mesentery. The blood-supply of the free margin is by this means more certain to be adequate. This rule holds for all transverse divisions of the bowel in any part of its course, large or small. If now the patient's condition is *not* good the distal end of the ileum above the ileo-cæcal valve can be turned in and sutured, cleansed and returned into the abdomen, or may be left hanging out of the wound unsutured but enveloped in gauze drawn round it with a tight strong thread, the rest of the procedure being deferred.

But the patient may be in good condition as regards blood pressure, respiration, &c., and it may be felt that the whole procedure of extirpation may be best completed at one sitting. If this be so the original gauze packing in one continuous piece such as I have always used is removed with no danger of leaving anything behind. It is otherwise if short pieces are employed. It is very easy to overlook one of them, especially when soaked in blood-stained serum. No detached small piece of gauze should ever in my opinion be allowed within the abdomen or other large wound which is not immediately taken out. The wound is now packed off again with a fresh gauze roller paid into it, while the still unrolled part is placed in a sterile box or towel on the abdomen. What is soiled can be from time to time withdrawn and cut off, while a fresh part is inserted from the roller. When the whole field of operation has been thus freshly guarded the peritoneum reflected from the cæcum and ascending colon to the parietes should be divided with scissors, one blade of which is inserted under it. There are few or no vessels to be considered here and no time is lost. This only becomes an anxious matter in the neighbourhood of the kidney, duodenum, and ureter, when the whole cæcum, ascending colon, and part of the transverse has to be removed, as was the case in the two patients to be referred to. When the peritoneum is divided great care must be taken to remove all glands and the surrounding areolar tissue in which the lymphatics run, together with the affected bowel.

The whole of the involved intestine from the ileo-cæcal valve to the anastomosis is by this time mobilised, and the inner part of its mesentery, which contains its vessels and lymphatics, can be well defined when stretched. The vessels must be carefully secured far from the intestine, but with great care not to include the superior mesenteric or trunk of the middle colic. The right colic can be tied off an inch from its origin, but the middle colic should not be ligatured until after it has given off its left colic branch, so that the anastomosis with the left colic of the inferior mesenteric be not interfered with. The corresponding veins will also require ligatures, and the fat and lymphatic tissues should be tied off with them.

By this time the whole ascending and part of the transverse colon are detached and the tube can be cut across an inch and a half from the previous junction with the ileum. This should be done between two Doyen's clamps placed close together, but not before a fresh turn of the gauze roller has been placed under the point of division. The separated portion containing the disease is carefully lifted away with all due safeguards as to avoidance of soiling with the fresh cut stump held in the clamp. The remaining proximal stump still held in the clamp is carefully cleaned and a second clamp is put on the bowel proximal to the first, and gently closed. Then the first, which should have been tightly applied, is removed, and the edges, which are found flattened together, are overcast easily with a suture. Having again been wiped over, the Doyen is taken off and the line of sutured bowel is pushed into the lumen beyond and a continuous sero-muscular suture applied to retain it there. The stump is cleansed again and the gauze packing removed in one strip.

It only remains now to revise the whole field of operation, close all bleeding points, remove any clots and loose shreds of fatty and areolar tissue, and suture the wound in the abdominal wall. This, as a rule, can be done completely at once in layers. If the packing has been carefully carried out from beginning to end, the edges—serous, muscular, and cutaneous—will be clean, and primary union will be obtained. But there may be a doubt on this point, in which case the wound is better only *partially* sutured over a gauze packing left in for 24 hours. But it is an enormous gain to the patient to get over the whole procedure once for all, and careful packing and manipulation will secure a degree of asepsis quite compatible with primary union. The earlier operations included drainage as a rule, but this was found to prevent in some cases the coaptation of the serous surfaces round the anastomosis and stumps, and the proper deposit of lymph around them, so that not infrequently a slight fæcal fistula was the result. This almost certainly closed in a short time, but was a blemish on the operation. Now with greater command over the technique of aseptic removal and immediate and complete closure of the abdominal wound such leakages are rare and primary union is the rule. If such is the case the after-treatment is simple. Fluid diet in small amount can be taken from the first day onwards, and after the bowels have been moved naturally, as they will be in a few days, semisolid and later full diet.

The cases alluded to in the title of this lecture appear in several ways as deserving of record, and particularly as illustrating the method of operation described. They have a further bearing upon the whole question of tubercle of the intestine and its treatment, which, however, is too large to be dealt with here.

CASE 1.—The patient, an unmarried female, aged 40, was sent to me in a very emaciated condition on account of a fæcal fistula in the right groin, dating from an operation for fæcal abscess about one year before, assumed to be due to appendicitis. At the operation a suspicion, I was told, arose that tubercle was at the root of the matter. Besides the fæcal fistula a large mass occupying the whole cæcal region could be made out when I came to examine the patient.

On June 25th, 1908, under spinal analgesia, I included the scar and fistula between two curved incisions and then stitched the two included skin edges over the fistula, using the threads besides to tie a thick layer of gauze over this to prevent any soiling of the subsequent deeper wound. Then the two incisions were deepened into the abdomen. It was then seen that the whole cæcum and most of the ascending colon were involved in advanced tubercle. Besides this, the last 18 inches or so of the terminal portion of the ileum were studded with tubercles as large as small peas (*vide* illustration). The cæcum was mobilised as above described, but with the greatest difficulty owing to very dense cicatricial adhesions all round and to the omentum. During the necessary dissection the cæcum gave way, but the hole was clamped, wiped, and enveloped in gauze. The hepatic colon was clamped, divided, and its end turned in and sutured. The ileum was now cut across over two feet from the valve and the whole tuberculous bowel with its mesentery and many infected glands removed from the abdomen as above. Then the end of the ileum was planted into the side of the transverse colon about two inches from its closed end. The whole procedure was a most complicated one owing to adhesion, infiltration, and glandular infection as well as the difficulty of determining how much of the ileum should be taken, for many small tubercles were scattered widely and I have no doubt that some were left behind above the line of junction. The wound was almost closed, but as there was some justifiable doubt as to the whole of the operation having been carried out without infection from the fistula and from the tear of the cæcum I thought it better to put a gauze drain into the upper angle. This was removed in a few days, but a sinus remained at the spot for a long time until the patient went to the country. Otherwise the rest of the wound healed perfectly. The operation lasted for 2¼ hours, but the anæsthesia was absolutely satisfactory to the surgeon and to the patient, who had expressed a wish to escape from chloroform. There was no sickness and no shock.

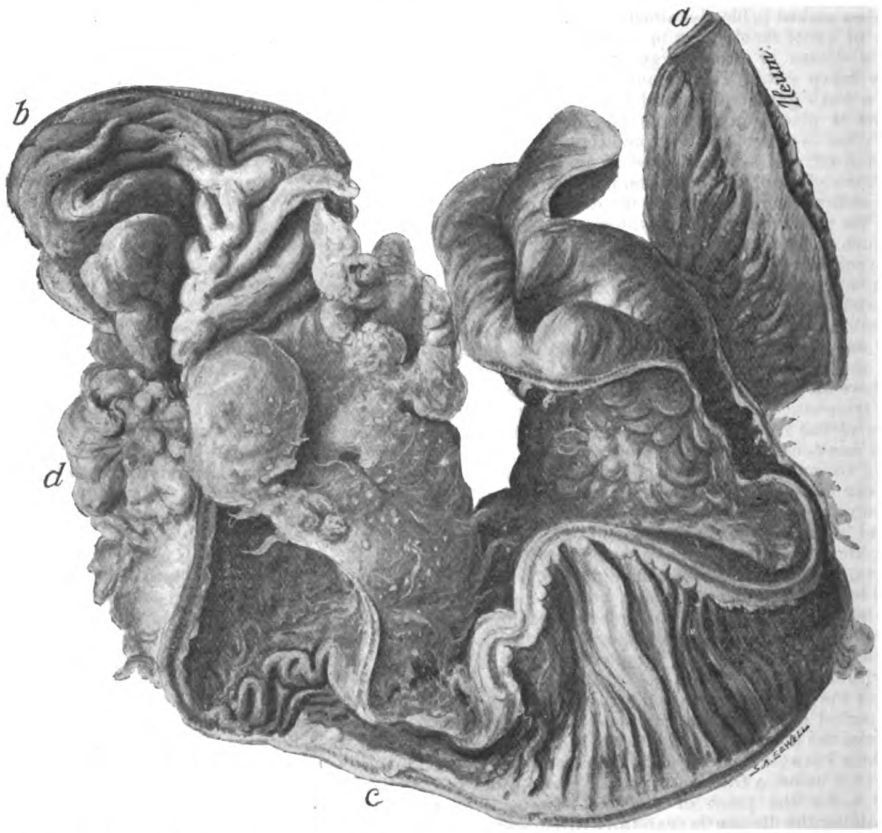
The parts removed (*vide* illustration) are thus described in the hospital surgical registrar's notes. "Cæcum with 4 inches of colon and 27 of ileum. Colon where cut through fairly healthy, though thickened and showing numerous tubercles on its peritoneal aspect. There is some ulceration of the mucous membrane, especially towards its lower end, where the whole circumference is ulcerated. Cæcum a mass of fibrous tissue, the walls ¼ to ½ inch thick and very rigid; lumen very small, mucous membrane greatly ulcerated, especially round the stump of the fistula. Some inches above the ileo-cæcal valve the lumen of the gut contracted by thick, fibrous material to such an extent that it will not admit the little finger. Above this in the ulcerated colon are five plum stones. The ileum shows numerous ulcerations of the mucous membrane, some healed, many recent, and encircling the bowel. About 22 inches up the ileum is a healed ulcer contracting the bowel. At the cut end the ileum, though thickly studded with tubercles, is

fairly healthy, showing no recent inflammation or ulceration."

I have recently seen this patient nearly three years after operation. She is plump and ruddy, and the bowels act regularly. Her local and general condition, in short, appears perfect, and her high spirits are remarkable.

CASE 2.—The patient, a soldier, aged 32, was sent to me as a case of probable carcinoma of the ascending colon. The diagnosis was based on a history of chronic intermittent obstruction and wasting with tumour in the flank, and on the discovery of a tumour from cæcum to hepatic flexure with infected glands during an exploratory laparotomy in December, 1910. Nothing further was done then and the wound was closed and healed per primam.

On admission, Jan. 23rd, 1911, the tumour, though large, appeared to me to have increased, but slowly, and the general condition to be less serious than might be expected in a young man who was known to have obstructive symptoms from tumour (presumably malignant) since at least the previous October. It appeared probable that the disease and the wasting might be due to tubercle, and this view gained support from the presence of tubercle bacilli in the sputa and the physical signs of dry phthisis in the right apex. The hope was justified that the symptoms might be due to a tubercular mass in the walls of the colon, as in the last case, and the glands only infected from this. After due preparation the same oblique skin incision was made as above, the muscle fibres separated, and the abdomen opened. The mass felt consisted of cæcum, infiltrated ascending colon, and hepatic flexure and glands obviously infected but not carcinomatous. This mass was widely adherent by fibrous bands to the border of the liver, kidney, and duodenum, and the omentum was also extensively adherent to it. The diagnosis of tubercle having been confirmed at once by a microscopic section of a gland, a lateral anastomosis of ileum to middle of transverse colon was made and the wound was closed. Spinal analgesia made the operation much easier than usual, but time had been lost in the examination of the relations of the tumour, and it was thought better to postpone the extirpation of the disease until a later period. At the end of a fortnight all was well, and the bowels had been thoroughly unloaded naturally through the anastomosis. The wound, which had healed per primam, was again opened up, and the last part of the ileum, cæcum, ascending and part of transverse colon up nearly to the anastomosis were excised with the same details as above. There were extra difficulties in this case in dissecting the mass from its adhesions with the liver, kidney, and duodenum, and in extirpating the widely infected glands. But in the further course of the case there is nothing to note except perfect recovery. There was no drainage, and the wounds healed without a flaw.



a, Divided ileum. *b*, Divided colon. *c*, Ileo-cæcal valve. *d*, Contracted portion of cæcum. All parts studded with tubercles.

When the man came back from the seaside to report himself he was in rude health, could eat any diet, and his bowels acted normally. The tubercle bacilli had disappeared from what he coughed up.

DONATIONS AND BEQUESTS.—Subject to certain legacies and conditions the Glasgow Royal Infirmary, the Western Infirmary, Glasgow, and the Victoria Infirmary, Glasgow, will receive about £40,000 each under the will of the late Mr. J. S. Dixon. The Glasgow Sick Children's Hospital will receive about £20,000.—The late Lieutenant-General Mostyn de la Poer Beresford has bequeathed £1000 to the Free Home for the Dying, Clapham Common.—The executors of the late Captain Ralph Slazenger have allocated £1000 of the £2000 left for charitable purposes for the endowment of a bed in King Edward VII. ward of the Royal National Orthopædic Hospital.—By the will of the late Mr. Edmund B. Gibson the Saffron Walden Hospital will subsequently receive £500.

THE OPERATIVE TREATMENT OF MALIGNANT DISEASE OF THE PELVIC ORGANS.

BY ALEXANDER DON, M.A., C.M. ABERD., F.R.C.S. EDIN.,
HONORARY SURGEON TO THE ROYAL INFIRMARY, DUNDEE.

MALIGNANT disease of the pelvic organs is so common and its operative treatment is yet so varied and on the whole so unsatisfactory that it is highly probable that no finality of method of dealing with the disease has yet been reached. The crux of the whole problem seems to be the disposal of the ureters and the eradication of malignant metastases in the walls of the pelvis. Were we sure that enlarged glands lying near the external and common iliac vessels were malignant many cases would have to be given up immediately on opening the abdomen. But these enlarged glands have been found so often to be merely inflammatory that though everyone is convinced that they should be removed whenever practicable few look upon them as an absolute bar to attempting eradication of the disease. The lymphatic distribution from the pelvic organs has been thoroughly worked out by innumerable investigators, and though their findings do not invariably agree it is safe to assume that no part of the pelvis proper can be held to be unaffected in malignant disease of its organs except the small part in front of the bladder, and that only when the disease is not primarily in the bladder itself.

The operation for malignant disease of the uterus, usually known in this country as Wertheim's operation, and the abdomino-perineal operation for rectal cancer, may be taken as examples of real attempts to deal radically with malignant disease of the pelvic organs, and in simple cases, and in the hands of practised operators, they have obtained a position in practical surgery. But the ordinary surgeon still dreads to attempt such delicate operations, and it is in his hands, chiefly from want of experience in the particular operation, that the mortality is excessive and injury to the ureters is so common. The latter accident is capable of rectification at the time if the damage is noticed by the operator, or may be cured by a later operation, but generally this is by the sacrifice of a kidney, or there is left intermittent difficulty with micturition.

In a case of cancer of the uterus I on one occasion was compelled to sacrifice a portion of the bladder with both ureters, and though the patient survived for a considerable time and died from an indefinite lung trouble the method adopted to benefit the urinary discomfort does not deserve more than a passing notice. In separating the uterus from the bladder the latter was opened, as was immediately evident, by tearing through the growth. Palpation revealed malignant infection of the bladder mucosa, covering an area of 1 by 1½ inches, with its long axis antero-posterior and involving the base of the bladder about the ureteric openings. This area, along with about half an inch of margin of healthy bladder tissue, was clipped away and removed along with the uterus. The ureters were divided before they reached the uterus but were not otherwise disturbed. After removal of the growth a few catgut sutures fixed the edge of the cut bladder to the front of the rectum a drainage-tube being left in each corner fixed by a catgut suture and protruding from the vagina. The patient made a normal recovery from the operation, but all the urine escaped per vaginam. This was rectified later by closing the vaginal orifice, and when the patient was last seen, a year after the second operation, she expressed herself as quite comfortable.

The operation was done five years ago and was by no means a complete one, and had the patient lived or even been available for examination of the pelvis a couple of years or so after removal of the tumour, in all probability some recurrence would have been noted; but as it happened she left the district, and only a meagre account of her last illness was obtainable from her friends. In discussing this case with another surgeon, I learned that in at least one case where part of the ureter had to be sacrificed a German surgeon had successfully grafted a shaving from the skin, cut slightly thicker than a Thiersch's graft and coiled in the form of a tube. Though no opportunity has yet been afforded of trying an alternative method, it seemed likely that if such a graft lived the ureters themselves would act better if they could be attached to another immoveable part of the bladder. The usual method of attaching them to the peritoneal surface exposes the ureters to periodic changes of tension, besides leaving them uncovered by peritoneum.

The following operation was done with comparative ease on a male cadaver. A Mackenrodt's incision, extending from one superior iliac spine to the other, and reaching to within half an inch of the symphysis pubis, divided all the structures of the abdominal wall. With the cadaver in the Trendelenburg position, the bowels were pushed upwards, an abdominal gauze cloth was packed in, leaving sufficient edge outside to cover the convex upper flap, which was then stitched at its centre to the tissues of the sacral promontory by one silkworm-gut suture. This effectually retained the intestines and gave an excellent view of the whole pelvis. The ureters and anterior division of the internal iliac vessels were located and the peritoneum opened by a vertical slit over the vessels, which were at once tied with a catgut ligature. The slit in the peritoneum was extended upwards to the division of the common iliac, and downwards along the side of the pelvic colon to the base of the bladder. The peritoneum was reflected outwards on both sides. The central flap of peritoneum was reflected upwards. The ureters were freed, from the brim of the pelvis to the base of the bladder, by blunt dissection and a few slips of a knife or scissors, care being taken not to injure them or their vessels by too close dissection or rough handling. The lower end of the ureter was gently pulled upon, and a pair of artery forceps occluded its vesical end, below which it was cut across. An opening was next made over the front of the bladder in the space of Retzius by reflecting the peritoneum from the lower side of the abdominal wound, and a pair of dressing forceps was passed from this opening under the peritoneum along the pelvic brim and out under the flap that had been dissected up. The end of the ureter was grasped by this forceps, and brought along the tunnel and pushed through a hole made in the front of the bladder. This can be done without the least tension on the ureter, especially if the outer edge of the fixed part of the bladder be utilised. A single silk suture fixed the ureter. The whole of the pelvis could then be cleaned out.

The operation was continued as for cancer of the rectum. The sigmoid flexure was pulled down till it became taut, and ligature of its mesentery was begun at this point. After the superior hæmorrhoidal artery is secured the rest of the mesentery can be stripped clean off from the brim of the pelvis down to about the top of the coccyx. There would be some hæmorrhage from the middle sacral artery, and probably from the lateral sacrals, but with a clear view of the pelvis these could easily be secured. If the base of the bladder be infected part of it can be removed without hæmorrhage as the vesical arteries are already controlled. Nothing need be left on the pelvic wall except the nerves and muscles. The colon was next ligatured in two places as low down as convenient, and divided between the ligatures with a knife, which was then discarded. The ends of the cut bowel are immediately covered with gauze to prevent any leakage. This is a speedier method than inverting the ends and needs less handling. It is also preferable to division by cautery, the handle of which cannot easily be kept aseptic. The long piece of colon was brought out at the left extremity of the wound and covered over, while the short end was dropped into the bottom of the pelvis. Division of the colon at this point does not make such a perfect specimen for preservation, and suggests a possibility of malignant infection, but this with the precautions mentioned above is hardly possible. The peritoneal flaps were next stitched together and completely closed the floor, and this diaphragm would be pushed right down to the bottom of the pelvis by the weight of the bowels. The upper end of the bowel was fixed into the left corner of the abdominal wound, and the rest of the incision closed by layer sutures. A rubber drain would be left in the space of Retzius as a precaution against urinary leakage. The rest of the operation could be done quickly and bloodlessly by any of the usual methods from below. If part of the bladder had been removed, there would be leakage of urine for a time and a drain would be necessary. In every case two-hourly catheterisation of the bladder must be done for ten days to allow the ureters to get quite firmly fixed.

If this operation be done with spinal anæsthesia there will

be practically no shock, and the operation should be finished in about an hour, no time being wasted in securing bleeding points. Krönig showed that both internal iliacs can be occluded without interference with the vitality of the bladder, and if the uterus is to be removed the superior hæmorrhoidal and sacral arteries would afford sufficient blood-supply to the rectum. If the base of the bladder were removed along with the uterus, which would seem to be almost necessary in cancer of the cervix, there would be leakage through the vagina, but this in malignant disease, which occurs late in life, may be rectified, as the vagina can be closed at a future time and made part of the bladder.

Hitherto all rectal operations for cancer, even Kraske's, have been followed by a huge mortality from shock, hæmorrhage, and sepsis. But by the method described the last could be almost abolished. Hæmorrhage in most of the low operations is very free, and the tying of vessels, even after the difficulty of catching them is overcome, is so awkward that sepsis is nearly certain to follow. Shock oftener follows pelvic operations in males, who do not seem to recover from loss of blood in such so speedily as do females, and whose pelves are not so tolerant of surgical interference. I have long been impressed with the idea that general anæsthesia, however induced, is followed by shock in proportion to the handling of sensitive tissues as much as from the length of time taken by the surgeon to do the operation. Afferent and efferent impulses are transmitted as if there were perfect consciousness, and only by blocking these impulses by spinal or local anæsthesia can shock in such cases be modified. The operation is recorded in the hope that specialists in pelvic surgery may consider its practicability.

Dundee.

THREE CASES OF CONGENITAL HEART DISEASE,

WITH NOTES OF THE FAMILY HISTORY RELATING TO THEM.

BY SIR DYCE DUCKWORTH, BART., M.D., LL.D., F.R.C.P.,

CONSULTING PHYSICIAN TO ST. BARTHOLOMEW'S AND THE ITALIAN HOSPITALS; SENIOR PHYSICIAN TO THE SEAMEN'S HOSPITAL, GREENWICH.

THE clinical story of these cases begins with a note relating to a lady, Mrs. A. B., and the particulars which I shall describe very concisely have come to my knowledge during the last 30 years. The details of the several defects recognised in the three cases have not been secured with accuracy, but the important facts as to their incidence admit of no doubt.

Family history.—Mrs. A. B. was one of several daughters of a gouty man who died over 80 years of age. Her mother was also long-lived, and appears to have suffered from some variety of chronic arthritis. Mrs. A. B. married at the age of 17 and went out to India with her husband, who was a rather delicate man, and died some years later at sea from chronic dysentery. One son, Mr. B. C., was the issue of this marriage, born in India. He has been healthy and vigorous and still survives at the age of 60, with some slight indication of a gouty proclivity.

Mrs. A. B. married a second time a sufficiently robust man, aged 47 years, and had by him two sons and three daughters, all now living and healthy. Soon after this marriage she became very stout (arthritic obesity). After 12 years this husband died from cardiac dilatation and hemiplegia.

Later, at the age of 37 years, Mrs. A. B. married a third time, the husband being a healthy man of about 30 years of age. In this man's family there were signs of gouty proclivity in both parents. (His father died at the age of 79 years from the effects of interstitial nephritis. He had Heberden's nodes, and these also developed in others of his children in later life, with obvious gouty symptoms.) During her pregnancy with her first child by this (third) marriage, Mrs. A. B. suffered from gouty pains in the joints, and began to lose a good deal of her obesity. A female child was born at term, somwhat small and weakly, and with a languid circulation. In the course of the second year of its life it was still feeble and backward, although not rachitic, and had a tendency to dyspnœa on exertion, and progressive clubbing of finger-ends, with duskiness of the lips. An examination of the heart at this time, by the late Dr. S. J. Gee, revealed the existence of a murmur in the pulmonary arterial area. The child remained delicate and died from scarlet fever in its thirteenth year.[1] There was no necropsy.

Eighteen months later Mrs. A. B. gave birth to a second daughter. This child was with great difficulty made to breathe on delivery, and was very cyanotic. It lived only 14 hours. A necropsy revealed a small opening in the septum ventriculorum and patent ductus arteriosus, and extremely small pulmonary veins. The mother had suffered for some weeks during her pregnancy from severe gouty pains in various parts of the body.

Two years later she gave birth to a healthy male child, who is still living and robust, and leading an active life.

In the course of the next three years Mrs. A. B. was found to be the subject of gouty glycosuria, little controlled by dieting. She lost weight very gradually and became feeble. She died at the age of 56 years from pleuro-pneumonia, having suffered from glycosuria in varying degree for 12 years. The husband has since his marriage had several gouty attacks of arthritis, lumbago, and phlebitis.

The third case of cardiac malformation occurred in the first child born to Mrs. A. B.'s son by her first husband. This son married a daughter of a distinctly gouty man, who had "regular" arthritic gout at intervals. Their first-born daughter showed obvious signs of congenital heart disease from an early date, suffering from dyspnœa, some degree of cyanosis, and backwardness in growth. There was a murmur heard to the right of the sternum, and the right ventricle was enlarged. This child hardly grew at all after eight or nine years of age and was very delicate. She died about the age of 13 years. There was no necropsy. A second daughter was born after this child and has maintained good health.

The children by the second husband of Mrs. A. B. have all grown up in satisfactory health. The eldest and second of the daughters and one of the sons have married and had normal children.

The third husband of Mrs. A. B. married a second time a daughter of an exceedingly gouty father, and has had two healthy children by her.

Remarks.—There are some noteworthy points in this remarkable family history. First, we find that the mother of the first son (Mrs. A. B.) came of a gouty stock. This son next married into a family with a gouty history, and his first child had a malformed heart. Secondly, we note that the children of the second husband of Mrs. A. B. were all free of such malformations. Thirdly, we find that two of the children by the third husband (gouty history on both sides of the family) had cardiac malformations. Fourthly, it appears that a coalescence of gouty proclivity in both parents in the third marriage tended to favour these malformations. This is in accordance with an apparent law that an intensification of any diathetic habit of body, both parents being the subject of it, leads to graver manifestations in the offspring.

I am not prepared to describe these instances just recorded as in any way indicating that such untoward sequels of the intermarriage of persons, each issuing from gouty ancestors, are to be regarded as common or likely to occur. I have no knowledge of any histories or literature in which such events have been noted or recorded. The facts related here are certainly striking and noteworthy, and I think they are worthy of publication if only to stir further inquiry.

Dr. A. E. Garrod[2] has recorded several cases of congenital malformation of the heart in which there was a strongly marked history of true rheumatism. In one instance the mother had rheumatic fever in the seventh month of her pregnancy. He directs attention to other deformities associated with the cardiac defects. In 11 out of 15 cases there was distinct history of rheumatic fever in near relations.

It is certain that subjects of the arthritic habit of body are specially prone to infection in early life by the specific (exogenous) toxins of rheumatism, and in later life to generate the (endogenous) morbid metabolic products which determine the onset of gout in many and varied phases.

It is now generally admitted that the cardiac malformations,

[1] Sir William Jenner was of the opinion that such children were bad subjects for the exanthemata.

[2] St. Bartholomew's Hospital Reports, vol. xxx. p. 53, 1904. "On the Association of Cardiac Malformation with other Congenital Defects."

of which we have clinical and pathological knowledge, are determined, and occur, about the seventh week of fœtal life.[3] Hence the old idea of shocks and strong maternal impressions during any period of pregnancy is now much, or altogether, discredited by pathologists as an etiological factor in such cases, and the majority of such cases are rightly to be regarded as developmental defects, and not as results of endocarditis in the embryonic stage.

While paying little attention to the idea of strong maternal impressions, we may yet suspend our judgment respecting the influence sometimes of lesions due to rheumatic, gouty, and syphilitic toxins on the fœtal endocardium. The latter are certainly most rarely met with. We have to remember that the placenta is permeable by micro-organisms and toxins, and further studies in this direction are very desirable.

THE VARIABILITY OF AGGLUTINATION OF B. TYPHOSUS AND M. MELITENSIS BY NORMAL SERA AND ITS IMPORTANCE IN LABORATORY DIAGNOSIS.

BY MILITARY ASSISTANT SURGEON E. C. R. FOX,
ASSISTANT TO THE DIRECTOR, PASTEUR INSTITUTE, KASAULI.

IN spite of the discovery of many new tests for the existence of specific bacterial disease the test of serum agglutination continues to hold an important place in diagnosis. This is especially the case for typhoid fever, and physicians still rely very largely upon laboratory findings for its diagnosis.

Now a very common question which is put by the physician who receives a report upon a serum which he has sent to a bacteriological laboratory is, What dilution of serum giving a definite agglutination am I to regard as diagnostic of typhoid fever? The laboratory report may only state the fact of agglutination in a given dilution and consider that that is all the help it can give in the matter. For purposes of discussion one feels inclined to alter the form of the physician's query, and ask, What dilution is to be regarded as affording strong evidence that the disease in question is typhoid fever? The answer should strictly be based upon the degree of certainty afforded by the reaction. In some cases the reaction cannot be regarded as justifying an altogether positive statement, and again different persons hold different views as to what constitutes certainty. One person is satisfied when the odds in favour are 10 to 1; another requires at least 100 to 1. We may put this in a more familiar form by saying that one diagnostician is pleased when his diagnoses are correct nine times out of ten, and another only when they are correct 99 times out of 100.

Agglutinations in low dilution cause particularly great difficulty, not only because of our want of exact knowledge of the variations which may occur in a healthy serum, but also because of the necessity for differentiation of the action of co-agglutinins. A "typhoid serum" will to a greater extent than a normal serum agglutinate B. coli, B. paratyphosus, and others of this group. A normal serum, again, will agglutinate the B. typhosus up to a certain dilution, and we require to know, not only to what dilution, but also the frequency of its occurrence. Lastly, different strains of the typhoid bacillus show great differences in their susceptibility to agglutination by typhoid, paratyphoid, and normal sera.

Now many standards have been laid down as to the degree of agglutination which is characteristic of typhoid fever. Most of these may be called safety estimates. Few of them refer to such points as the degree of agglutinability of the particular laboratory strain used with normal sera, and seldom refer to the degree to which confusion with paratyphoid disease may occur. An ideal way of expressing the results of an agglutinating test would be to give it in this way:—

Agglutination with B. typhosus up to 1 in 64; probabilities against the serum being normal, 10,000 to 1; against its being a B. paratyphosus serum, 80 to 1; against its being a B. coli serum, 50 to 1.

I have only taken the odds at random in order to illustrate and explain the principle which is involved. But how are these probabilities to be arrived at? Briefly stated, they are to be obtained by an application of statistical methods. Thus they may be obtained for normal sera by examining a very large number of healthy individuals as to the agglutinating power of their sera—so large a number as to give, by its very largeness and uniform distribution of values, approximately actual probabilities of occurrence for any given dilution. But it is almost impossible to obtain numbers large enough to satisfy this requirement. The next method would be to take a reasonably large number of individuals, set down the frequency distribution of agglutination dilutions, and fit a curve to the observations. This curve would give the real probabilities with a correctness which would depend partly on the actual numbers observed and partly on the degree of variation found. But to fit such a curve to a distribution requires a mathematical knowledge which many laboratory workers like myself do not possess.

The worker who has not the knowledge, and who is dissatisfied with such a very defective presentment of his facts as an average or a single percentage, has still a method open to him. It consists simply in giving the whole of his results in the form of a frequency distribution, and calculating by simple arithmetical procedure the measure of the variability of that distribution. It may then be possible on certain assumptions and in simple cases to calculate the probabilities for and against a particular value corresponding, as the case may be, to a normal state or to a specific diseased state. It is most important, also, to state exactly the circumstances under which the frequency distribution has been constructed. This last precaution is required in order to set at rest any doubts which might arise regarding the possibility of selection of cases. My own work refers to the differentiation of test typhoid and Mediterranean fever sera from normal sera. My cases were simply taken haphazard from amongst the patients attending the Pasteur Institute for anti-rabic treatment. I think I may, therefore, exclude the possibility of selection here. The individuals were all adults—natives of India.

The calculations of variability and probability referred to above have not been actually made because the successive dilutions used in testing the agglutinating power were, through inadvertence, increased not additively but as simple multiples of each previous dilution. That is to say, the intervals between my groups were not the same throughout, which they ought to have been. The frequency distributions only are given.

TABLE I.—*Agglutination B. Typhosus with Normal Sera; Strain "Douglas."*

Emulsion killed at 60° C. for half an hour; 0·5 per cent. carbolic acid added.

Dilutions of serum.	Under 2	2	4	8	16	32
Frequency	38	55	17	1	1*	0

* History of long-continued fever 12 months ago.

All agglutinations were taken to their end point as given by the series of dilutions 2-fold, 4-fold, 8-fold, 16-fold, 32-fold, 64-fold, and so on. Only the complete agglutination was recorded. An agglutination at a 4-fold dilution, and negative at 8, might have agglutinated at the point 6, and it is unfortunate that these intermediate values were not determined throughout. The series by simple multiples, however, allows of a simpler technique.

Looking at the distribution, we see that the agglutinations given by normal sera are very low, quite a large proportion not giving the reaction even in a two-fold dilution. In order to determine (1) what the effect of heating of the emulsion and addition of carbolic acid might be on the agglutinability of the organism, and (2) what the variations in agglutinability of different strains might be, the following observations were made:—

TABLE II.—*Agglutinations Using Three Different Strains of B. Typhosus.*

"Living." Normal sera. 109 observations.

All strains compared were first standardised to give approximately emulsions of equal density of suspension. Thus the cultures used were all of 24 hours. Culture tubes in which the density of growth was uniformly distributed were selected, and normal salt added in quantity proportional to the area covered by the growth. This precaution was

[3] For an admirable discussion of the whole subject the reader is referred to a communication by the late Dr. George Carpenter in the Royal Society of Medicine Transactions, vol. ii., No. 9, July, 1909.

necessary in order to exclude as far as possible differences in agglutination due purely to differences in the density of the emulsions used.

Strain "Douglas."

Dilutions of serum.	Under 2	2	4	8	16	32	64
Frequency	2	18	53	31	5*	0	0

Mean = 5·3, or excluding the fever cases 4·8.

* 3 had a history of long-continued fever.

Strain "Berlin."

Dilutions of serum.	Under 2	2	4	8	16	32	64
Frequency	0	16	30	47	13*	2†	1†

Mean = 7·9, or, excluding fever cases = 6·9.

* No history of fever.

† Had a history of long-continued fever.

Strain "Kral."

Dilutions of serum.	Under 2	2	4	8	16	32	64
Frequency	0	0	0	0	0	1	108†

† Not put up to higher dilutions.

The conclusions to be drawn from these tests are:—

1. There are probably few sera which do not agglutinate B. typhosus at least in a two-fold dilution.

2. Strain "Berlin" gave agglutinations with higher dilutions of sera than strain "Douglas," but nothing much over 16-fold was likely to be frequent.

3. Strain "Kral" was agglutinated with normal sera up to a dilution of 1 in 64 and over. As a matter of fact, this strain agglutinated even with physiological salt solution.

It is obvious, then, that a laboratory finding must vary considerably with the particular strain used, and therefore it is very essential to have a knowledge of the peculiarities of the strain used. It is quite possible, too, that a given strain might in course of time alter as regards its agglutinability with normal sera. Such conditions might be those afforded in the plains of India in the hot weather. Strain "Kral" evidently could not be used in our laboratory agglutination tests, and the choice of a strain lay between "Douglas" and "Berlin."

TABLE III.—*"Douglas" and "Berlin" Strains.*

"Living" emulsion. Showing the agglutinations obtained with the same individual's serum on 30 consecutive days.

Strain "Douglas."

Serum dilutions.	Under 2	2	4	8	16	32	64
Frequency	0	1	28	1	0	0	0

Strain "Berlin."

Serum dilutions.	Under 2	2	4	8	16	32	64
Frequency	2	3	16	8	1	0	0

From these distributions we see that strain "Berlin" varied in its agglutination more than strain "Douglas," even with one and the same individual's serum. I chose strain "Douglas," therefore, for the final test of agglutinability with normal sera.

TABLE IV.—*Strain "Douglas" B. Typhosus.*

Living emulsion; sera of healthy individuals; 500 observations.

Serum dilutions.	Under 2	2	4	8	16	32	64
Frequency	6	92	223	146	29*	4x	0

* 8 gave a history of long-continued fever.
x 4 " " " "

The sera of healthy individuals, therefore, as far as these observations go, do not agglutinate B. typhosus "Douglas" in higher dilutions than 1 in 16, or possibly 1 in 32. The probabilities, accordingly, in favour of a dilution of 1 in 64 being abnormal are likely to be higher than those of its being normal. We cannot, for want of the necessary observations, consider the case of B. paratyphosus as against B. typhosus. These are being carried out.

The question of co-agglutinations or of group reactions has never arisen in the case of M. melitensis, and the problem of differentiation of specific sera from normal sera becomes here comparatively simple.

TABLE V.—*M. Melitensis: Frequency Distribution of Agglutinations.*

Emulsion killed at 60° C. for half an hour. 0·5 per cent. carbolic acid added. 612 observations.

Serum dilutions.	Under 2	2	4	8	16	32	64	128
Frequency	184	349	60	15	2*	1x	1x	0

x Definite clinical histories of having had Mediterranean fever recently.

* No history of fever. One of these two individuals, a laboratory attendant, showed a very high phagocytic count to Mediterranean fever. In this individual, however, the opsonin was thermolabile, as the following experiment shows.

Mediterranean fever serum, thick emulsion	35·1§	Mediterranean fever serum heated 60° C.–15 minutes— Thick emulsion	28·0§
Serum of laboratory attendant, thick emulsion	21·3§	Thin "	6·3§
Mediterranean fever serum, thin emulsion	4·4§	Serum of laboratory attendant heated 60° C.–15 min.— Thick emulsion	0·3§
Serum of laboratory attendant, thin emulsion	4·3§	Thin "	0·2§

‡ Obtained from a patient suffering from Mediterranean fever.
§ Phagocytic count per leucocyte.

The serum of this laboratory attendant, then, gave a high agglutination and a high phagocytic count, and yet there is no reason from a consideration of its phagocytic action to suppose it other than a normal one.

But before closing this investigation into the agglutinating power of normal sera on B. typhosus and M. melitensis, it will be interesting to give some indication of the degree of agglutination which can be met with in typhoid fever and Mediterranean fever respectively. Instead of taking proved cases of typhoid and Mediterranean fever, I have had to take simply cases sent for investigation and suspected of being typhoid and Mediterranean fever. Only dilutions of 1 in 8 and upwards were used, as it is difficult to get serum for lower dilution from blood capsules sent to the laboratory.

B. Typhosus.

Serum dilutions... ...	8	16	32	64	128	256	512	Mean = 120·2
Frequency	4	6	7	9	11	4	4

Frequency...	0	0	0	2	3	3	0	1	1	1

Remarks.

1. All strains of organisms used for the agglutination reaction should be tested quantitatively as regards agglutinability.

2. The laboratory strain used should be tested against the sera of as large numbers as possible of healthy individuals.

3. The laboratory strain should be tested against the sera of as large numbers of persons known to be suffering from the disease caused by the specific organism, and also of persons suffering from diseases caused by allied organisms, before differentiation between the diseases can be attempted by means of the agglutination test.

My grateful thanks are due to Captain W. F. Harvey, I.M.S., Director, Pasteur Institute of India, for initiating this investigation and for help and advice throughout.

Kasauli.

MEDITERRANEAN FEVER: ITS INFLUENCE ON THE FŒTUS IN UTERO.

BY ROBERT SAMUT, M.B., C.M. EDIN.,

SURGEON-MAJOR, K.O.M.R. OF MILITIA; CHEV. UFF. CROWN OF ITALY; LECTURER ON PHYSIOLOGY, MALTA UNIVERSITY.

THE following case differs from that related by Major E. M. Williams, R.A.M.C., in the July number of the *Journal of the Royal Army Medical Corps* for 1907, inasmuch as the blood of the fœtus gave a positive reaction to Mediterranean fever at birth. The possibility of extra-uterine influence is entirely excluded in this case, since the fœtus was stillborn at the fifth month of gestation.

The patient, aged 17 years, was admitted on Jan. 22nd, 1911, to the Central Hospital, Floriana, suffering from fever of a fortnight's duration. Temperature 103 5° F., tongue furred, anorexia, constipation, pulse frequent, headache, urine normal, spleen enlarged, pregnancy (about five months). Treatment: benzonaphthol and salicylate of quinine. The patient's blood was examined and found to give a positive reaction to the Micrococcus melitensis in a large dilution. On Jan. 28th the patient aborted, and the fœtus was brought to the laboratory for examination, which was performed six hours after abortion.

There was no sign of putrefaction or maceration. The cord was cut, but was fresh and gelatinous. In order that no trace of the mother's blood should remain adherent to the surface of the fœtus its body was washed with soap and water, and then thoroughly rinsed in distilled water The left jugular vein was incised but yielded a mere trace

of blood; the whole of the left side of the neck was then incised, but still the quantity of blood obtained was insufficient for examination. Sufficient quantity of serum was obtained in sterile capillary tubes from the heart cavities, and the agglutination test was performed in various dilutions with an eighth generation culture of Micrococcus melitensis.

Dilution ...	1 : 40	1 : 80	1 : 200	1 : 300	1 : 500
Agglutination ...	Immediate. Complete.	4 min. Complete.	12 min. Complete.	20 min. Complete.	40 min. Slight.

The test was also applied to a small quantity of cerebro-spinal fluid obtained in a sterile capillary tube from the cerebral ventricles, with similar results—viz., a positive reaction with a tenth generation culture of Micrococcus melitensis in a dilution of 1 : 300.

Smear preparations were now made on nutrose-glucose-litmus agar from the spleen pulp, heart muscle, and brain. These were incubated in a Hearson incubator at 37° C. for four days. A growth was noted after 24 hours in the Petri dish over which the brain emulsion had been stroked, and as this could not be the Micrococcus melitensis it was put aside for examination, but was accidentally exposed to contamination and therefore disca ded. The remaining Petri dishes showed no sign of growth after four days' incubation, and none after a further period of three days.

Conclusions.—1. The fœtus in this case had been exposed in utero for 21 days to the influence of those abnormal conditions of the maternal blood consequent upon a severe attack of Mediterranean fever.

2. The child's blood and cerebro-spinal fluid yielded a positive reaction to Micrococcus melitensis in large dilution.

3. The Micrococcus melitensis could not be recovered from the internal organs of the fœtus.

4. Acute infectious diseases are known to be transmitted by the maternal blood to the fœtus in utero, endangering or interrupting pregnancy. Thus cases of intra-uterine variola are by no means rare, while intermittent fever has been known not only to attack the fœtus, but in some instances the attacks have continued after birth, and in all the child had at birth an enlarged spleen (Felkin, Goodell and Harris, Bonfils). There seems to be no reason, therefore, why Mediterranean fever should not be transmitted from mother to child during gestation.

5. The presence of agglutinins alone in the present case raises the important question whether, in the absence of the Micrococcus melitensis in the fœtal organs, they could have been elaborated by the fœtal blood, or whether they were transmitted directly from the maternal to the fœtal circulation.

Sliema, Malta.

ACCIDENTS WHICH HAVE OCCURRED THROUGH COLOUR BLINDNESS.

BY F. W. EDRIDGE-GREEN, M.D. DURH., F.R.C.S. ENG.,
HUNTERIAN PROFESSOR OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; BEIT MEDICAL RESEARCH FELLOW.

I HAVE written this article because of the continued repetition of the mis-statement that no accident has ever been shown to have occurred through colour blindness.

One of the most extraordinary circumstances in this connexion is the refusal of the authorities to have the eyesight examined of those who are responsible for a collision caused by an error in the interpretation of the coloured signals. I am not aware of a single case in which either the Marine or the Railway Department of the Board of Trade has had the colour perception of an officer responsible for a collision examined, even by the very imperfect methods which are official with them. A man might just as well say that no person had ever died from a very common disease because this disease required for its certain diagnosis a microscopical examination of the blood, and this examination was never made.

I am also precluded from giving those cases in which officers have consulted me because they have found difficulty with coloured lights, and have caused, or nearly caused, an accident. I can with the greatest ease show how dangerous it is to employ colour-blind persons by testing them with my lantern in which the same colours are shown as those in their daily employment. Definite mistakes between the red, green, and white lights are made in a few seconds; and if the examinee be in control of a miniature engine or ship, which he has to direct by the lights, he will soon display his incapacity. I have demonstrated cases of colour-blind men who have passed the official wool test, and shown how they may be made to call green red, and red green, by the proper selection of the colours and their sequence.

Apart, however, from the difficulties which I have just mentioned, there are many cases of accidents which have been proved to be due to the colour-blindness of those in charge. The following is to be found on page 6 of the Annual Report of the Supervising Inspector-General of Steam Vessels to the Secretary of the Treasury, Washington, 1880:—

On the night of July 5th, 1875, there was a collision near Norfolk, Va., between the steam-tug *Lumberman* and the steamship *Isaac Bell*, the former vessel bound to, and the latter from, Norfolk. The accident occurred at about 9 P.M. on an ordinary clear night, under circumstances which, until recently, seemed more or less mysterious. The master of the steamer and all his officers made oath that at the time signals were made to the tug the latter was from one to two points on the steamer's starboard bow, and consequently the steamer's green light only was visible to the approaching vessel. Yet the master of the tug, whose statement was unsupported by any other testimony, asserted that the steamer's red light was exhibited, and he signalled accordingly. The discrepancy in the statements was so great that many persons uncharitably charged the master of the tug with being intoxicated, although no evidence was ever offered in support of the charge. By this accident ten persons lost their lives. Upon a visual examination of this officer under the rules during the past summer—namely, four years after the accident happened, and during which time there had been no question as to his sight—by the surgeon of the marine hospital at Norfolk he was found to be colour-blind, two examinations having been accorded him with an interval of ten days between them.

It is to be particularly noted that the colour blindness was not discovered in this case at the time of the accident, but four years afterwards.

The following is a record of an accident occurring through colour blindness. Mr. Haynes Walton, in a letter published in 1877,[1] says, with regard to acquired colour blindness:—

A few years ago I was investigating colour appreciation, and the first instance of the acquired defect that came to my knowledge was in the person of an engine-driver. This man confessed, after an accident through his not distinguishing the red signal, that he had gradually lost his colour power, which had been perfect; and so sensible was he of his loss and its disadvantages that before the accident he had determined to give up the situation.

The following case is related by Dr. S. T. Armstrong.[2] He says:—

The master and owner of a steamboat on the Mississippi river brought a man to me for examination for colour sense. The man proved to be colour blind and on looking over the records his rejection several years previous was found; the man said he had not expected to pass, and stated that his steamboat had once collided with and sunk a steamboat on account of his inability to distinguish the signal lights. His would-be employer was aware of these facts.

The following case occurred in 1881[3]:—

Colour-blindness, New York, June 18th.—The pilot of the steamer *City of Austria*, which was lost in the harbour of Fernandia, Florida, last April, is proved to be colour blind. In this it would appear that he mistook the buoys, and his mistake cost the owners 200,000 dollars (£40,000). An examination showed that at a distance of more than six feet he could not distingush one colour from another. The physicians attribute the defect to an excessive use of tobacco. The services of the Marine Hospital surgeons were tendered to the local authorities without fee two years ago, but were declined.

The following is related by Dr. Joy Jeffries:—

Dr. Gintl, chief inspector of one of the Austrian roads, got the report of an accident due to colour blindness on the Finnish Road between Helsingfors and Tavastchus in July, 1876. It was caused by a colour-blind switch-tender showing a green instead of a red light to the approaching train.

The following quotations from two letters are very interesting:—

1. I have been on the railway for 30 years, and I can tell you the card tests and the wools are not a bit of good. Why, sir, I had a mate that passed them all, but we had a pitch into another train over it. He couldn't tell a red from a green light at night in a bit of a fog.[4]

2. Some years ago a collision occurred on a railway in consequence of a train over-running a signal; the driver was firm in his statement that the light was "green," whereas all the other men said it was "red." The driver was fined and afterwards continued at work as usual. He then made some other mistakes, which would have ended in collisions had not the fireman said, "Stop, mate." Without any cause being stated the driver decided to give up railway work and take to another occupation.[5]

[5] A letter by Mr. Stretton, published in Engineer, Dec. 6th, 1889.

The following is written by Captain Coburn[6]:—

The steamer *Neera* was on a voyage from Liverpool to Alexandria. One night, shortly after passing Gibraltar, at 10.30 P.M., I went on the bridge, which was then in charge of the third officer, a man of about 45 years of age, and who up to that time I had supposed to be a trustworthy officer, and competent in every way. I walked up and down the bridge until about 11 P.M., when the third officer and I almost simultaneously saw a light about two points on the starboard bow. I at once saw it was a green light and knew that no action was called for. To my surprise, the third officer called out to the man at the wheel "Port," which he was about to do, when I countermanded the order and told him to steady his helm, which he did, and we passed the other steamer safely about half a mile apart. I at once asked the third officer why he had ported his helm to a green light on the starboard bow, but he insisted it was a red light which he had first seen. I tried him repeatedly after this, and although he sometimes gave a correct description of the colour of the light, he was as often incorrect, and it was evidently all guesswork. On my return I applied to have him removed from the ship, as he was, in my opinion, quite unfit to have charge of the deck at night, and this application was granted. After this occurrence I always, when taking a strange officer to sea, remained on the bridge with him at night until I had tested his ability to distinguish colours. I cannot imagine anything more dangerous or more likely to lead to fatal accidents than a colour-blind man on a steamer's bridge.

A similar experience is thus related by Captain Heasley of Liverpool:—

After passing through the straits of Gibraltar the second officer, who had charge of the deck, gave the order to port—much to my astonishment, for the lights to be seen about a point on the starboard bow were a masthead and green light; but he maintained that it was a masthead and red, and not until both ships were nearly abreast would he acknowledge his mistake. I may add that during the rest of the voyage I never saw him making the same mistake. As a practical seaman, I consider a great many accidents at sea arise from colour blindness.

The following case is related by Mr. T. H. Bickerton in the *British Medical Journal* of 1887:—

A captain of a large Atlantic steamer, in answer to my inquiry as to whether he had ever come across a colour-blind man, gave me the following information.

One night, while lying in his berth, he heard the officer on watch sing out, "Hard a port!" He at once rushed on deck, and asking the officer what was the matter was answered: "Red light ahead, sir." He looked, and seeing on the starboard bow a green light at once had the helm starboarded. He could not understand how such a mistake could be made as the officer was considered to be an experienced one. On a subsequent occasion a somewhat similar occurrence took place. The order, "Hard a port!" was given, and on the captain hurrying on deck he found that the man had mistaken the pyrotechnic lights by which vessels at night signal the name of the company to which they belong, and which was shown on the starboard side of the advancing vessel for its port light. On each occasion a probable collision was only averted by the prompt intervention of the captain. On the owners of the vessel being informed by the captain of these incidents the man was examined, found to be colour blind, and dismissed.

Mr. Bickerton gives a most convincing example of how an accident may occur through colour blindness, and also of the inadequacy of the official Board of Trade methods. He writes in the *British Medical Journal*, Vol. I., 1900, p. 621:—

In February, 1897, the 4000-ton steamer *D*——, belonging to Liverpool owners, was in the North Sea. The time was night, and the second officer, who had passed for second mate in 1894 and first mate in 1895, was on the bridge. By accident the captain came on deck, and was horrified to find his vessel making straight for an approaching sailing ship. The second officer had seen the approaching craft's green light and mistaking it for a white one, supposing it to be exhibited on some stationary craft, kept his course. A minute or two more and it would have been too late to avert a disaster, and probably the resulting collision would have sent one, if not both, vessels to the bottom. As it was, however, the captain grasped the situation at once and promptly starboarding averted the danger of collision, but not until the two vessels were less than a length apart.

On reaching home the officer was re-tested by the Board of Trade and passed as possessed of normal vision. He went to sea again. He freely confessed that he could never distinguish with certainty a green from a white light.

This and the previous case are even more convincing than those in which accidents occurred, because accidents were only obviated by the prompt action of the captain.

One of the latest is the wreck of the British steamship *Australia* at Port Phillip on the morning of June 20th, 1904 The pilot who caused the accident was subsequently examined and his vision was found to be: right eye 6/36 partly, left eye 6/36 partly.[7] The colour vision, tested by Holmgren's wools, was normal, but tested by luminous discs considerable illumination was required to elicit a satisfactory discrimination of some of the colours. The same pilot was in charge of the ss. *Indraghiri* on March 10th, 1904, when she ran aground to the north-west of the entrance to the South Channel. The night was dark but clear, and the lights were visible. The pilot, however, failed to see the occulting light at No. 15 buoy. It is noteworthy that if the pilot had been examined after the wreck of the *Indraghiri* the wreck of the *Australia* would probably have been prevented.

I have not given those cases of collisions which have occurred on a clear night, and for which no apparent cause was to be found, and of which the lay papers state that it would have been thought that only a madman or a blind man could, in the conditions, have caused an accident. The examples I have given show that colour blindness of the navigating officer is an easy explanation of the mystery.

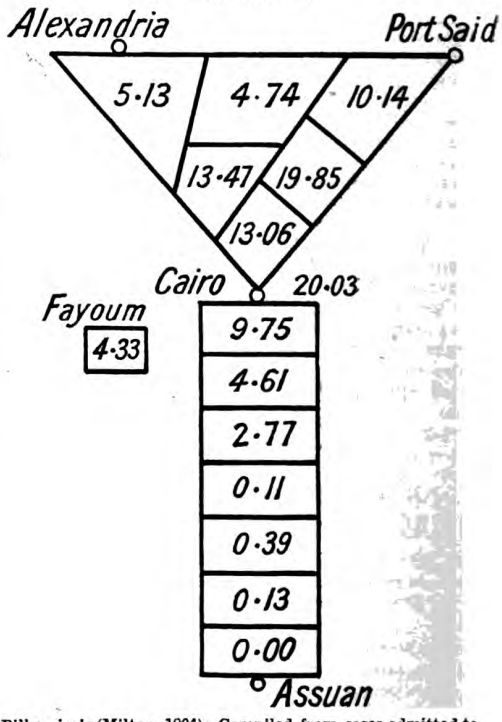
NOTES ON BILHARZIOSIS AND ANKYLOSTOMIASIS IN EGYPT.

BY G. W. G. HUGHES, M.R.C.S. ENG., L.R.C.P. LOND., CAPTAIN, R.A.M.C.

Bilharziosis.

IN the Records of the Egyptian Government School of Medicine for 1904 are some interesting notes by Mr. Frank Milton on cases treated at the hospital and found to be suffering from bilharziosis. He tabulated them according to the provinces from which they came, working out the number of cases per 100,000 of population of each province. I have shown these figures in a diagram (1), giving roughly

DIAGRAM 1.



Bilharziosis (Milton, 1904): Compiled from cases admitted to Kasr-el-Ainy Hospital, Cairo. Figures represent proportion of cases per 100,000 of population of each province. *Note.*—Cairo: Probably most of these cases came from the provinces originally.

the geographical position of the provinces, the triangular portion representing the Delta, with Cairo at its apex; the elongated portion the long, narrow valley of the Nile of Upper Egypt, with the Oasis of the Fayoum on the west. Mr. Milton says:—

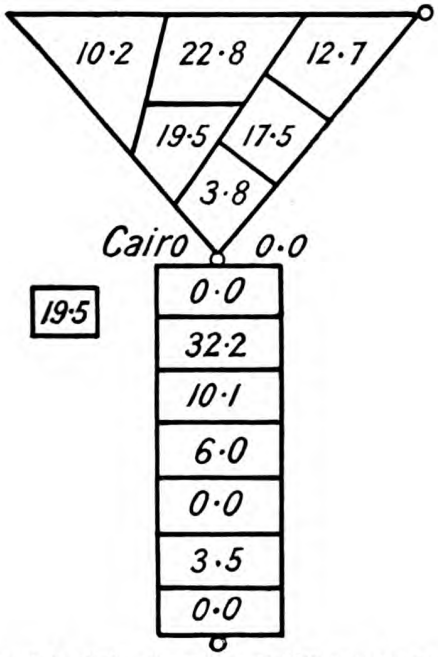
The disproportion between the number of cases of bilharzia from the two natural divisions of the country is so very marked that there must be some very well defined cause constantly acting, and this, I believe, is to be found in the way in which water is supplied to the different provinces for the purposes of irrigation. ..... Thus the peasant from Lower Egypt has a much longer period of time during which he is exposed to the chance of infection, and infection is more frequently repeated than is the case with his brother in Upper Egypt.

The difference in the water-supply referred to is that in Lower Egypt (the Delta) the land is watered perennially,

whereas in most of Upper Egypt "basin irrigation" is employed, and the land is dry for many months in the year.

The Egyptian army is a conscripted army, and the recruits are examined and selected by medical officers in the various provinces, and the required numbers are sent to Cairo, where they are again medically examined. Part of this second examination is a microscopic examination of the urine. The men sent to Cairo are all apparently healthy and strong, but as many as 7·5 per cent. of these are found to have bilharzia ova in the urine. Out of 1516 found fit in the provinces, 115 were found to have bilharziosis. In the second diagram I

DIAGRAM 2.



Bilharziosis (1910): Percentages of 1516 men apparently healthy and fit for the army and found to have bilharzia in urine.

have distributed them according to the districts from which they came, to compare with the first, but the numbers are really too small to give an accurate idea of the distribution. It must be remembered that these are young men of 21 years of age.

Ankylostomiasis.

One of the most striking results of ankylostomiasis in the young is the stunting of growth. When the young men of Egypt are called up at 19 years of age to be balloted, two classes are at once rejected—(1) those who are blind in one eye or in both, or are deformed or maimed; and (2) those who are under 155 cm. (5 ft. 1 in.) in height. I wish to draw attention to this second class.

The average height of these "short men" is about 150 cm. (4 ft. 11 in.), and it is found that though a very small number of them may be really under age and others are normally undersized, the great majority are suffering from obvious anæmia, or show evidences of having suffered from it. Not only undersized, but with childish voices and genitals, one would gauge their age at 12 or 14 rather than at 19 years.

The numbers of these unfortunate boys give a very good idea of the extent of the ravages of ankylostomiasis among the male population in Egypt. In the third diagram the figures represent the percentage of youths rejected as being under 155 cm. As in the diagrams for bilharzia, the Delta shows a far greater prevalence, the figures becoming lower towards the south. Another noticeable point is the comparison between the large towns of Cairo and Alexandria and the rest of the country.

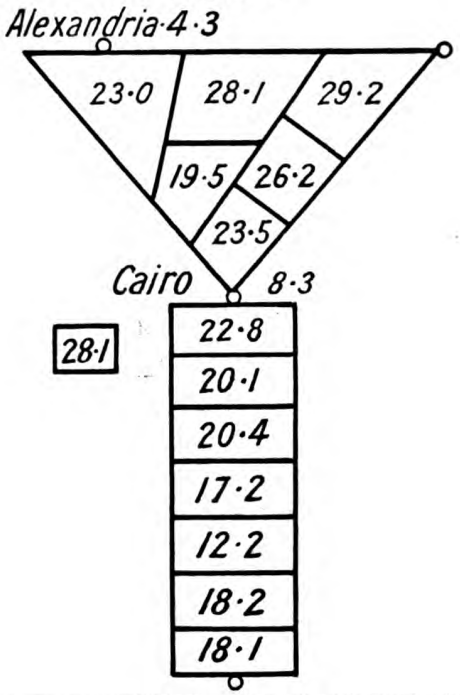
These figures do not represent, of course, the full numbers of men who have this "Egyptian chlorosis," far less of those who harbour the ankylostoma. If they represent anything, they only give an idea of the number of those who have suffered so severely from the disease between the ages of about 10 to 16 years that their growth has become stunted.

Remarks.

Are not the figures rather appalling? It is impossible not to be impressed by the shocking waste of life and waste of labour caused by these diseases. The huge percentage of eye diseases is more obvious, but not more serious. As regards eye diseases, it is pleasant to note that the educative influence of the travelling eye hospitals inaugurated by Sir E. Cassel is bearing fruit, and that in many of the principal towns permanent eye hospitals are being erected by public subscription.

But can nothing be done for ankylostomiasis and bilharziosis? Nothing at all is being done at present. Prophylaxis seems almost impossible, or at any rate so large and so difficult a task that one cannot blame the already over-worked and under-staffed public health authorities for their inaction. Could not the idea of a travelling eye hospital be utilised? Apart from the actual relief such a hospital gives to its patients, the *educative influence*, already

DIAGRAM 3



Ankylostomiasis (1909): Percentages of youths found under 155 cm. when 19 years of age.

referred to, is most important. Treatment by anthelmintics might be given free in every town where there is a government hospital. Thymol, however, is not a drug which it is advisable to sell wholesale without medical supervision, as quinine is sold to the public at post offices in India. But I am not sanguine enough to believe that the native in the country can be persuaded, or taught, or induced, within many generations, to observe European ideas of cleanliness. He works in mud, his house is of mud, and his habits are filthy.

Cairo.

ST. BARTHOLOMEW'S HOSPITAL MEDICAL SCHOOL.—An examination will be held at St. Bartholomew's Hospital on Sept. 25th and following days, on the results of which the scholarships enumerated in the Students' Number of THE LANCET (August 26th, 1911, p. 571) will be awarded. The successful candidate in each case will be required to enter for the full course as a student at St. Bartholomew's Medical School immediately after the examination.

X RAY TREATMENT OF SARCOMA:

A CASE OF ROUND-CELLED SARCOMA OF THE RIGHT ANGLE OF THE LOWER JAW IN WHICH COLOSSAL DOSES OF X RAYS PROVED EFFECTIVE.

BY J. DELPRATT HARRIS, M.D. DURH., M.R.C.S. ENG.,
HONORARY MEDICAL OFFICER IN CHARGE OF THE ELECTRICAL DEPARTMENT, ROYAL DEVON AND EXETER HOSPITAL.

THE following case may prove useful in marking out a new line in the use of X rays therapeutically.

The patient, a boy, aged 4 years, was brought to the Royal Devon and Exeter Hospital for a small swelling over the ascending ramus of the jaw on the right side. As he had at the time a catarrhal condition of the auditory meatus on both sides, the swelling was thought to be glandular, and the ears were thoroughly treated until the discharge ceased. During the next month the swelling became much larger, the whole bone on that side appearing implicated and the enlargement being now noticeable both inside the mouth and externally. A fortnight later the swelling had increased in size and a point of softening was noticed on the inside. At this time (June 25th, 1910) the case was admitted.

On admission the patient was drowsy and took very little notice. The temperature ranged between 98° and 100° F., rising on July 4th to 103·4° in the evening. On July 5th, under chloroform anæsthesia, an exploratory puncture in the mouth was made, and some soft material was removed for microscopical examination. Some slight gouging and examination with a probe was made in order to ascertain whether tubercular disease of the bone existed. No evidence of this was obtained. On July 11th the pathologist reported: "The growth proved to be small round-celled sarcoma."

After the operation the patient became more drowsy than before, the skin over the tumour becoming reddened and softened as though about to break down. The temperature ranged between 101° and 104°. Inside the mouth the condition was that the swelling was so situated that the teeth could not be made to touch, and mastication of food was prevented, the teeth chewing the tumour and causing a line of ulceration. Coley's fluid was now injected: July 15th, ♏ ½ was given; 16th, ♏ ¼; 17th, ♏ ⅜; 18th to 20th, ♏ ½; 22nd, ♏ ¾; 23rd and 24th, ♏ 1; 25th, ♏ 1⅛; July 26th to August 3rd, ♏ 1½. After the injections, which were given in the forenoon, the patient usually had an evening reactionary temperature of 101° to 102°, the temperature becoming normal in the morning. As a result of nearly three weeks injections, the swelling was noted as being "much smaller, the skin becoming normal in appearance, and the general condition much improved. The fluid was sometimes injected into the tumour, at other times into the arm."

On persevering with this treatment it was noted that reaction was still obtained on August 20th, but on Sept. 9th, although ♏ iv. were given as one dose, no reaction was obtainable. The case being now in a latent condition and no further benefit appearing, on Sept. 18th, 1910, what must be called a colossal dose of X rays was given, since the word massive has already been used for far smaller doses. The child was prepared for the ordeal by being given a mixture of bromide and chloral in small doses during the day. A regenerating X ray tube (sparking from mica type) in good condition being selected, a glass shield and cylinder were used to protect other parts of the face, and to maintain the proper Sabouraud distance; an aluminium filter was used about half a millimetre in thickness; and the tube was illuminated with a 100 volt current, so arranged that 5 ampères passed through the primary of the induction coil. This on being measured gave a good Sabouraud dose in rather less than 20 minutes. This current was maintained for six continuous hours, from 6 to 12 P.M., with a short interval at 9 P.M. to soften the tube. This was made up later.

The house surgeon's notes run: "On next day the side of the face was very red, and later some inflammation of right tonsillar region. The temperature rose gradually for three days (Sept. 19th to 21st) from normal to 103·6°, but remained normal on Sept. 25th. There is a very definite recession in the apparent size of the growth. The outline of the jaw can be felt on all sides of the tumour. The ulcerated surface inside the mouth was quite healed on Sept. 25th."

On Sept. 28th a second dose of the same length of time and quantity was administered, being the fourth day of normal temperature. The house surgeon's note runs: "Tumour now feels about the size of a hen's egg and quite hard, arising abruptly from the inferior maxilla. No egg-shell crackling obtained."

On Nov. 9th my own notes run: "The condition now is that all soft parts of the tumour are more or less absorbed, and hence the projection into the mouth, and also on the cheek, is much reduced. The boy can chew and shut his mouth and open it widely. The bony condition is, however, one of considerable expansion still, but harder as though condensing. His general condition is much improved, and he is now lively and boyish. Seen from the foot of his bed, the two cheeks are not dissimilar." On Oct. 29th, and again on Nov. 26th, the same dose was repeated, being four colossal doses of 18 Sabouraud doses each.

I have omitted to state that on August 25th and twice a week after, for five times in all, the patient was given single Sabouraud doses during the administration of Coley's fluid. It was the failure of this treatment and that of Coley's fluid that induced me to try such large doses.

The child was now much improved in appearance and had put on many pounds weight. His parent desired to have him home, and he was made an out-patient. Owing to domestic circumstances his treatment was discontinued in December, but on Jan. 14th, 1911, another colossal dose was administered, there being a small lump palpable under a good layer of fat, for he was now fairly "chubby." He did well, and was regarded by his relatives as cured, and was allowed to play in the public grounds with other children.

In the month of May he was brought with the history of being knocked on the jaw by another boy whilst playing. On examination the tumour was much swollen out, and the teeth were kept apart by growth in the mouth as at first. It was hoped the great enlargement might be hæmorrhagic, and cooling lotions were at first applied. Later one colossal dose was given on May 13th, but no marked result followed, and finding that he was likely to sink shortly the mother removed him to her home to die there rather than in hospital. Thus the case ended untowardly, although there seemed every hope at one time that the daring treatment might prove permanently successful.

I have not read or heard of so large a dose being given, but I was driven to it by the hopelessness of the case in one so young, and the fact that radium treatment lends itself to prolonged sittings; for whilst radium rays are not X rays nor serve the same purpose, yet there is a similarity. I was also influenced by an expression I saw in the *Archives of the Roentgen Ray*, in which it was stated that "a good kick sometimes does more good than several slight pushes."

I believe there is a future for this form of treatment, and I have another case of cancer of the jaw undergoing similar treatment. Should others wish to try such colossal doses I wish to urge them to regulate their coils not to exceed in quickness 17 minutes to the Sabouraud dose, to filter with aluminium, and to take the temperature night and morning. One of my difficulties lay with the toxins which were liberated. Unless the temperature does rise no great good seems to occur, but it must be normal when the next colossal dose is given.

I think Coley's fluid did good at first, but the boy soon grew immune to it, and on reaction failing to occur no further benefit ensued. It is noteworthy that single Sabouraud doses given during the treatment by Coley's fluid produced no marked reaction. It seems improbable, then, that the reaction following the first colossal dose was in any way due to Coley's fluid, and none had been given for 12 days prior.

It seems clear that X rays are capable of producing necrotic changes of the cells, by which certain products are liberated which can be taken away by the lymph channels: these, on finding their way into the general circulation, set up febrile action, as large doses of tuberculin used to. It is for us to find out how much of this toxin the individual patient can contend with, and how large a dose of X rays is necessary to liberate the required amount in such cases as prove themselves amenable to this form of treatment.[1] I

[1] The thickness of aluminium used in this case was determined by our engineer as gauge 24.

wish to acknowledge the care shown by our then house surgeon—Mr. Vernon Starr—in keeping so clear a record of this important case, and also by Sister Hussey of the electrical department in carrying out so conscientiously the long sittings.

Exeter.

NOTE ON A CASE OF

ACUTE PLASTIC IRITIS, MARKEDLY BENEFITED WITH ANTISTREPTOCOCCUS SERUM.

BY A. A. BRADBURNE, F.R.C.S. EDIN.,

OPHTHALMIC SURGEON TO THE ORMSKIRK HOSPITAL AND DISPENSARY, AND TO THE SOUTHPORT EDUCATIONAL AUTHORITY.

ON April 11th, 1911, I was asked to see, in consultation, a patient, aged 46 years, who for three or four days had been suffering from very acute pains in his legs, back, and chest. The previous day unmistakeable evidence of pleurisy had been found, and so severe had the pains been that four injections of morphine had been given in 24 hours.

I found the patient in bed, looking flushed and anxious. There was intense hyperæmia of the ocular and palpebral conjunctiva of the left eye. The cornea was so hazy as to almost occlude the iris, which could be dimly discerned lying attached to the lens capsule, causing naturally a very deep anterior chamber and a contracted pupil. Vision was reduced to light perception. The ocular movements were normal, the tension was high, but there was no tenderness to pressure. The right eye was normal.

Salicylates and potassium iodide had been given previous to my visit with the idea of combating what looked like an attack of rheumatism. Examination of the patient's teeth revealed the presence of suppuration around the roots, and this feature led us to come to the conclusion that the condition was due to a staphylococcal or streptococcal toxæmia. To settle this point a sample of his blood was taken and sent to Dr. A. Ramsbottom of Manchester. Meanwhile the iodide was stopped, and the dose of the salicylates increased to 20 gr. every four hours. Local treatment to the eye consisted of fomentations and drops containing dionine, atropine, and cocaine.

The patient passed a very good night, quite free from pain, but on his medical attendant visiting him next morning he found the right eye starting a similar but less intense attack, for which he promptly instilled a weak solution of belladonna. On my seeing him I found that the mydriatic in the right eye had dilated the pupil, leaving in the centre of the pupil a deposit of lymph. Atropine was immediately instilled, but only very little further dilation could be obtained, and again it left another ring of exudation on the lens capsule. The condition of the left eye was practically unchanged. In neither eye could any deposits of lymph (keratitis punctata) be made out.

The patient was removed to a nursing home. During the next 24 hours the atropine drops were continued, but the only result was to produce a peculiar tucking up of the pupillary margin of the iris. On the third day a report was received that the examination of the blood confirmed the view that the condition was streptococcal in origin, and upon this it was decided to inoculate with antistreptococcus serum. At 1 P.M. an injection of 10 c.c. of Messrs. Parke, Davis, and Co.'s antistreptococcus serum (polyvalent) was given. At 3 P.M. the temperature went up to 99° F., and the patient complained of itching of his left eye. At 7 P.M. the eye became more injected. This evidence of local reaction was particularly pleasing, and when he was seen next morning it was found that the deposit of lymph on the lens of the right eye had completely gone, and the liquefaction of the exudation had enabled the atropine to start dilation of the pupils. At the same time the texture of the iris became evident, its markings having previously been obscured by the lymph.

No medicine had been given since the injection. The patient was free from pain and had slept well, and was apparently perfectly comfortable and much brighter since he found his vision so improved. Forty-eight hours after the injection the right pupil became fully dilated and the left to three-quarters. In the left eye a curious condition was to be seen. Extending from the cornea to the anterior surface of the lens was a cone-shaped solid semi-transparent mass, bearing a striking likeness to a lump of camphor. Its broad expanded base was attached to the posterior surface of the cornea; its apex, resting on the lens capsule, corresponded to the size of the originally contracted pupil. As matters progressed this mass rapidly melted away, and in four days all that was left was a centrally situated nodule, surrounded by a series of concentric rings slightly coloured with iris pigment.

A second sample of blood had been submitted, and the report stated that there was undoubted evidence of streptococcal infection, and advised a second injection. This was accordingly done, but it caused a rise of temperature and upset the patient generally, without producing any particular benefit. The patient remained in the home for three weeks, and had all his teeth removed, the majority of which were found to be the seat of alveolar suppuration at their roots. A scraping taken from the root of one failed to grow any micro-organism whatever. I saw him finally on May 23rd and could find but very little trace of the recent trouble. The pupils were equal and active, there was not the merest spot to be found anywhere on the lens capsule or cornea of either eye. There was, however, some vitreous haze in the right eye, close behind, if not on, the posterior surface of the lens at its nasal side, and in the left all over the posterior pole, but in both eyes it was little more than a veil.

Since this case came under my notice I have received Darier's latest work, "Ophthalmic Therapeutics," and in it he makes the following statements:—

> The anti-diphtheritic serum is the only specific serum that has been recognised in ocular therapeutics. ..... At present we possess few sera the action of which is really specific. Meanwhile, ought we not to find out whether certain serums do not possess, in addition to their purely specific action, therapeutic properties that may be utilised in infections of a less serious nature or that have some analogy with the specific infections.

This case seems to show that certain antitoxic serums, even if they do not possess specific action, have marked therapeutic properties of liquefying and aiding absorption of the exuded lymph. Whether the good results were in any way due to the previous use of salicylates or not this one case cannot prove. It, however, proves the utility of antitoxic sera, as without it the case could scarcely have made such rapid and astonishing progress. Another question which seems of interest is whether the case was really one of the manifestations of so-called rheumatism of streptococcal nature. The fact that the salicylates relieved the intense pain seems to support this idea. One would be glad to have the views of bacteriologists and others on this case.

Manchester.

A CASE OF SYPHILITIC NECROSIS OF THE CERVICAL VERTEBRÆ.

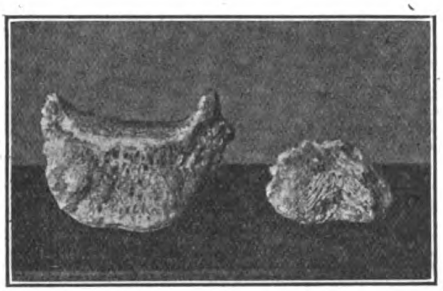
BY F. X. J. CALLAGHAN, M.B., B.CH., D.P.H. R.U.I.,

SENIOR PHYSICIAN TO JERVIS-STREET HOSPITAL, DUBLIN.

THE patient, a female aged 23 years, was admitted to hospital on August 17th, 1910. In 1906 she had contracted syphilis. The primary infection was very marked, so much so that portions of the vulval and vaginal mucous membranes were destroyed. Three months later she had suffered from sore-throat and a "spotty red rash." She was not medically treated for either the primary or secondary symptoms. In June, 1909, the patient was treated in the out-patient department of Jervis-street Hospital, Dublin, by Mr. J. L. Keegan for an ulcer on the right side of the neck. The ulcer had healed readily under antisyphilitic treatment. In June, 1910, the patient began to suffer from pain in the neck and from difficulty in swallowing; she was treated for this condition in another hospital and obtained some temporary relief from an operation performed on her throat (the throat was approached from the side of the neck, not through the mouth). On August 17th she was admitted to Jervis Street Hospital by Mr. Keegan, who kindly placed her under my care.

On admission the temperature was 101° F., the pulse-rate 130, and the respirations were 30. The patient complained of severe pain in the head and the neck. The pain was relieved by supporting the head on the hands, and was intensified by movement. The head was held thrust forward, the chin being directed slightly upwards. There were extreme rigidity of the neck and tonic contraction of the sterno-mastoid muscles, the cervical glands were enlarged on both sides, there was marked tenderness on pressure over the

upper cervical vertebræ, and the pupils were obstinately contracted. The patient complained also of pain and difficulty in swallowing. I was unable to examine the condition of the throat, as the attempt to open her mouth at all widely caused her extreme pain. Except for rigidity of the arms, I found no other signs of irritation or compression of the cord or nerves. The heart and lungs were normal. The symptoms pointed to pressure on the cervical portion of the cord, and a diagnosis of gumma pressing on this portion of the cord was made. The patient was given 10-grain doses of potassium iodide with 1/16th grain of perchloride of mercury three times daily, and was kept as quiet as possible. Though unable to swallow solids, she could swallow fluids in small quantities. On August 19th the patient stated that she felt something sticking in her throat, "something which felt like a piece of bone." The throat, however, could not be examined owing to the extreme pain which the necessary manipulations caused. Later in the day the patient coughed up a large piece of bone, which on examination proved to be the greater portion of the body of one of the cervical vertebræ (probably the third), the upper and lower anterior borders and the upper articular surface of the body being plainly shown on the fragment. Another fragment, apparently a



Reproduction of a photograph of necrosed fragments of cervical vertebræ.

portion of the body of the second, was coughed up some hours later. From this date the patient improved rapidly. The pain and difficulty in swallowing disappeared, but the rigidity of the neck persisted to such a degree as to suggest ankylosis of several cervical vertebræ. She was allowed to get up in ten days' time and when last seen (November, 1910) presented no abnormal sign or symptom beyond the cervical rigidity. She now wears a metal support for the chin and occiput attached to a jury-mast, and is thus protected from the disastrous consequences which would ensue were her neck suddenly bent forwards; the support also removes some of the weight from the weakened vertebræ.

The measurements of the larger fragment were as follows: Greatest transverse diameter, 2·1 cm.; vertical diameter, 1·3 cm.; and antero-posterior diameter, 1 cm.

The case was apparently one of syphilitic necrosis of a portion of the cervical vertebræ, followed by the formation of a sequestrum which was subsequently extruded through the posterior pharyngeal wall and so coughed up. I think the rigidity which is now present is due to the formation of new bone welding together the bodies of the upper cervical vertebræ.

Reference to the literature of the subject shows that syphilitic necrosis of the vertebræ is a rather rare condition; it usually affects the upper cervical vertebræ and begins in the anterior portion of the bodies. It starts as a periostitis which is followed by death of a portion of bone; a rarefying osteitis now takes place at the junction of dead and living bone, and so a sequestrum is formed. Subsequently the periosteum may form new bone.

As to the diagnosis, syphilitic necrosis may give rise to all the clinical features of tuberculous caries, but the onset in the former is more sudden and the progress more rapid. In most cases valuable information is obtained from the history of the patient, the presence of other evidences of syphilis, and by noting the effect of antisyphilitic treatment.

I wish to thank Mr. Keegan, surgeon to the hospital, for kindly allowing me to publish this case.

Dublin.

PORTAL PYÆMIA AND HÆMORRHOIDS.[1]

BY DAVID A. ALEXANDER, M.B., CH.B. VICT.

THE subject of the following account, a master workman, was at the time to which it refers (February, 1910) in appearance and form in the prime of physical manhood. The family to which he belonged, a numerous one and widely scattered, exemplifies in its various branches the usual morbid diatheses. One of his children is distinctly oxycephalic. In himself the only constitutional peculiarity to be noted was blanching or empurpling of the fingers and hands—that local asphyxiation which culminates in Raynaud's disease. I had previously attended him in September and in November, 1909, for attacks of which he had had a succession during recent years. With sudden abdominal pain in the right lumbar and iliac regions, tenderness, nausea, and dysuria, they suggested to me the passage of a renal calculus, being similar to those in another patient whom I was simultaneously attending, and in whom, without the confirmatory proofs of blood in the urine or the testicular direction of the pain, the symptoms at last abated with the expulsion of several small stones. There was no rise of temperature that I discovered during these attacks; they did not last long; the patient kept his bed for a day or two, and then resumed work.

On Feb. 16th, 1910, when I saw him, he had been seized with pain in the night on the right side of the abdomen as before, but there was now an area of tenderness and resistance in the appendicular region, and he had a temperature of 100° F. On the third day these symptoms were subsiding. But the patient did not, as on former occasions, quickly recover himself; he kept his bed, with an air of weariness, which left a misgiving as to his real condition. On the 21st a gangrenous odour was perceptible, which investigation showed to be due to a sloughing hæmorrhoid. The patient then stated that he had long been subject to piles, and that they had occasioned him no small inconvenience. The pile occupied the right side of the anal ring, was as large as an almond, and had prolapsed from within. It quickly sloughed off, leaving a tender area within the anus. There now appeared no reason to expect a delay in convalescence; there was no abdominal pain or tenderness. Temperature was absent, the pulse was steady, and the patient was quiet. I did not think him morbidly apathetic. Shortly, however, an icteric tinge was visible in the eye and skin, and bile appeared in the urine. The patient's wife also reported that he had had "shakings" in the night, the significance of which statement I overlooked and regarded the jaundice without apprehension. On the 26th, ten days after the onset of illness, going in at 9 A.M. I witnessed a rigor. It was impressive in its severity. The patient became deeply cyanosed; his teeth chattered; he shook; the bed shook; his temperature rose to 105·5°, the pulse-rate to 120; he was in great distress for 15 minutes, then began to perspire, and regained composure, but was much exhausted.

At this juncture he was seen with me by Mr. T. Carwardine. It was clear that we had to do with a virulent infection the seat of which was to be located or removed. Looking over the past history, it was very doubtful whether the earlier attacks were renal. So far, only bile had been found in the urine. The local signs of appendicular mischief were not in evidence, some pain only being elicited by deep pressure in the right loin. There was a little flatulent distension of the abdomen, but no hepatic tenderness or increase of dulness or splenic enlargement. Of typhoid infection, recent or remote, there was no proof. The breath had an acetous odour. There remained the anal area and the site of the sloughed pile. Here the canal was found to be still tender to the touch, bleeding slightly. The rectum, considerably ballooned, presented on the right side some resistance to the examining finger as though the walls were thickened. Nothing comparable to an abscess sac was encountered. It seemed reasonable to consider the anus as the site of infection, to attribute the pain to phlebitis in the portal veins, and in the icterus to see proof that the liver was already invaded. This was not a condition for operative intervention and only

[1] A paper read at a meeting of the Bristol Medico-Chirurgical Society.

the gravest prognosis could be offered. The patient was removed to a nursing home for greater care or possible emergencies.

Day now succeeded day without diminution in the recurrence or the violence of the rigors. The whole picture of the disease was one seldom to be seen outside tropical clinics, composure and apparent safety suddenly changing to danger and distress. In a fortnight the patient was much wasted; the feet and legs were œdematous, abrasions appeared at bony prominences, here and there were minute ecchymoses, and small subcuticular abscesses began to form.

In March the crural veins of the right leg became thrombosed, signified by increased swelling and persistent pain. Meanwhile the local condition of the anal canal had improved. No collection of pus could be detected in the rectum, although a little was now and then apparent in the motions. The urine now began to run clear of bile, the rigors to cease, and the daily range of temperature to fall. By the middle of April, however, the pulse began to flag, concomitantly with the discovery in the abdomen of free fluid and another rise in temperature. After eight weeks of a septic state, therefore, sometimes expressing itself in a hyperpyrexia of 107° and with the complications already seen, little ground of hope remained.

Rallying again, the patient passed another fortnight without increase of abdominal fluid, with recovery of heart force, freer urinary flow, and declining temperature, and in this condition he returned to his own house.

In May increasing pain and localised tenderness of the right calf pointed to abscess formation, and on the 21st, under local anæsthesia, an incision was made and about a pint of foul greenish pus was evacuated. Continual irrigation followed until, in three weeks, healing was complete.

A favourable course now seemed to open, but it was interrupted towards the middle of June. Gastric discomfort was complained of and dyspnœa; the temperature, reduced almost to the normal, again showed an ascent, and these symptoms were associated with extension from the flanks and rapid increase of ascitic fluid. Large veins appeared in the hypogastrium, the whole abdomen was distended, and the parietes were œdematous. This condition was relieved on June 27th by the insertion of a trocar and with the escape of some quarts of clear fluid. Thenceforth ascites was controlled by diuretics and purgatives; cutaneous œdema lingered for a while only and the enlarged veins ceased to be visible. Convalescence followed, and a visit to the country was possible in August.

In October an attack of two days' duration recurred similar to those of the preceding year, with pain of the same distribution and with a slight rise in temperature. In the time which has since elapsed the patient has regained his former weight and vigour, and maintains them, complaining neither of pain nor hæmorrhoids.

It will now be asked what the bacteriology of the infection was and what it contributed to treatment. First, of the urine: it yielded nothing; there were neither tubercle bacilli, as evidence of chronic tuberculosis, nor colon bacilli. Blood drawn from a vein on March 3rd, when the rigors were frequent, proved also to be sterile. It showed a moderate leucocytosis. The subcuticular abscesses were not investigated, being abraded almost as soon as formed and prone as they were to surface contamination. When the crural abscess was emptied in May it yielded a streptococcus brevis, and provided to Professor I. Walker Hall the means for an autogenous vaccine. One administration, indeed, of polyvalent serum had been made in the early days of the infection, but it happened that afterwards the patient was more than usually prostrate, and no second dose was given. So with a vaccine; there was no encouragement to continue what might not be a specific at all. When at last the autogenous vaccine was in our hands the time for its value to be proved had passed. With the crural abscess the septic process had come to an end; the abdominal distress, ascites and anasarca, as it turned out, depended on no fresh focus of infection, but rather was a mechanical result of portal obstruction, and I hesitated to use it.

A few observations may be made upon the course and incidents of the illness. The patient was a good patient; he took gratefully all the care shown him and the comfort he derived from assiduous nursing. He was content, not to say cheerful, even when, as his weakness deepened, he ceased to expect his restoration. He slept much; was often delirious, too, and required a sedative. His appetite was always better than his alimentation; he wanted common food, even whilst his motions were large and fetid or tympanites was calling for turpentine enemata. He took much milk, and of brandy some four to six ounces daily when at the worst. Intestinal antiseptics (excepting iodoform suppositories) were not given continuously. Utropine was early discontinued. Strychnine was frequently required, especially after the severer rigors. Quinine was given at the beginning in 5-grain doses. From perchloride of iron, in large doses, I believe he derived advantage, and perhaps also later on from the sulphates of iron and magnesium.

The temperature charts presented a fair conspectus of the case. Evening rise and morning fall were not quite regular during the first month, and the constancy of the temperature was then further broken by the recurring seizures. Of these some 30, the greater number, were crowded into 13 days. The daily range at this time lay between 98° and 104°, exceptionally exceeding the latter, as on March 3rd, when 106·6° was recorded with and also without a rigor. In the first half of April the reading was 98° to 100°. Irregularity and perceptible rise accompanied the appearance of ascites and cardiac feebleness of that time. In the middle of May pyrexia was only slight, until the crural abscess pressed for relief, when 100° was again reached. And the same rise from an almost normal was repeated at the end of June when the trunk was dropsical. The pulse record 80, 96, 120, 130, followed remission or exacerbation of other symptoms.

Reviewing the whole case, I think it probable that all the previous seizures were of the nature of the last: in the former a limited tract of the hæmorrhoidal veins being thrombosed; in the latter, extension having taken place, there resulted, what must be rare in the experience of any—portal pyæmia as a complication of hæmorrhoids. There may remain a lingering doubt whether, in his present seeming perfect health, the patient has lost the disposition to reinfection—a doubt which qualifies one's satisfaction at his recovery.

Clifton.

THE PREVALENCE OF PULMONARY TUBERCULOSIS IN THE MERCHANT SERVICE.

BY MURDOCH MACKINNON, M.D. EDIN., D.P.H. OXON.,
MEDICAL REGISTRAR, LATE MEDICAL SUPERINTENDENT, SEAMEN'S HOSPITAL, GREENWICH.

THERE is a widespread belief that a seafaring life is one of the most effectual remedies in the treatment of those who suffer from "weak chest," and no doubt to a certain extent and under favourable conditions this is true. Life at sea would naturally appeal to the lay mind as an ideal one for people in indifferent health, and especially for those with any tubercular tendencies, in that the open-air treatment is to be obtained here in its truest and most economical form. But when one inquires into the circumstances under which the sailor lives on the sea there are many fallacies intimately connected with this belief, and the benefit derived is in many cases meagre compared with the disadvantages and even danger closely associated with such a life. Not only is tuberculosis a very prevalent disease among sailors, as I shall try to show in this paper, but also cardio-vascular diseases and their effects are extremely common. The latter, however, are rightly attributed more to hard work, alcohol, and syphilis—a trio still closely connected with the sailor—than to inefficient accommodation and ventilation. I shall confine my remarks, therefore, to the influence of the latter defects on the incidence of pulmonary tuberculosis among the sailors.

To the patient who is already affected with pulmonary tuberculosis, and who can afford time and expense, a long sea voyage is still recommended as one of the best means of overcoming the effects of the tubercle bacillus. Undoubtedly in many cases much benefit is derived, and better results still would be expected in accordance with the present-day idea of treating tuberculosis if certain facts were taken into consideration. First, cases should be selected, and only those in which the disease is in its early stages and not rapidly advancing should be recommended for a prolonged sea.

voyage with any prospects of permanent benefit. Secondly, variations in temperature and climate ought to be taken into consideration. Long periods of bad weather, with frequent and sudden changes of temperature, produce very deleterious effects on patients suffering from diseased lungs. During these periods the patient is confined to his cabin, where more often than not the accommodation provided is very unsuitable and the conditions under which he lives, as far as ventilation and supply of pure air are concerned, are for the time being worse than they would be at his own home on land. Hence it is not surprising to find that many patients do not gain any material benefit from the treatment, and this no doubt accounts to a large extent for the disrepute into which it has of late years fallen.

It might be expected, however, that the sailor who presumably commenced his seafaring life in good health would maintain perfect health, and of all people would be the least liable to contract tuberculosis. In the merchant service, from which the statistics given in this paper are derived, such is not the case. The prevalence of the disease is marked and the suffering produced enormous. No better proof could be required of the infectious nature of pulmonary tuberculosis than that supplied by the frequency of that disease among the sailors, the vast majority of whom have no hereditary tendencies to that disease, but, on the contrary, are physically of such build and good development as to preclude any suspicion of that taint. When, however, a single member of a crew suffers from tuberculosis he becomes a grave danger to all the others. The insufficiency of the cubic space provided, the lack of proper ventilation and aeration, especially in cold weather, in addition to the want of sufficient sunlight—all these deficiencies aid in an unmistakable way the growth and dissemination of the tubercle bacilli. The increase of temperature below decks, especially in the engine-rooms and stoke, helps to dry the expectoration which is spat indiscriminately in all parts of the ship visited by the infected person. This dried sputum is constantly blown about by currents of air, is inhaled by others, or may be deposited on food or in drink exposed to the atmosphere. Fortunately, however, in the healthy and strongest members of the crew the tubercle bacilli, even if inhaled in the manner described, do not find a favourable medium for their growth and development, and the individual maintains good health owing mainly to his own powers of resistance. There are others, again, who from the nature of their ratings are less favourably disposed. Firemen, engineers, greasers, cooks, and stewards pass most of their time below deck in stuffy atmospheres, in ill-ventilated, dark, and dusty rooms, with the too frequent result that in the course of time anæmia is produced, health deteriorates, and they readily become a prey to the tubercle bacillus. Additional factors, such as the abuse of alcohol, venereal diseases, irregularities in diet and sleep, are all most potent causes of the debility and deterioration in health which precede and increase the susceptibility to pulmonary tuberculosis.

At the Dreadnought Hospital merchant seamen of all nationalities are admitted and treated. A special department of the hospital is set aside solely for tuberculosis, and open-air treatment is adopted in such cases as are definitely diagnosed as tuberculosis. Under this treatment, combined with as much nourishment as the patient can possibly consume, the results are good in many of the cases. After a stay varying from a few weeks to many months some of the patients gain vastly in strength and weight, and the disease appears for the time being to be quiescent. This, however, only holds good in those cases in which the disease is at its earliest stages. In others more advanced improvement is only temporary, and eventually a time comes when the patient begins to dislike his food; he gradually loses weight and strength, and the temperature gets more hectic in type until he dies. Patients of the former class, in the course of a few weeks or so, improve to a certain extent, and insist on leaving the hospital, under the impression that they are quite well again, or, at all events, that they are sufficiently recovered to resume their usual employment. The majority of these patients, however, after varying periods of absence in comparatively good health, eventually return to the hospital in worse condition than when they were previously admitted. These are the cases which are a source of great danger, in that they disseminate the disease, and not only make matters worse for themselves but infect their fellow shipmates, and thus, as it were, complete the life cycle of the disease.

To remedy this serious state of affairs there should be a definite understanding that no patient who has been treated for tuberculosis of the lungs should ever be admitted to the merchant service. By the aid also of thorough medical examination, and of inquiries into the previous state of health, all tuberculous cases should be rejected. By this means material aid in diminishing the incidence of, and the death-rate from, tuberculosis among seamen would be given.

The following tables have been compiled to show the total number of admissions to the Dreadnought Hospital of patients suffering from pulmonary tuberculosis in 21 years (1890–1910 inclusive); the annual number of admissions under each class and the death-rate; also the percentage death-rate from phthisis calculated from the total number of deaths from all causes. In Table I. is given the total annual number of admissions under each rating; in Table II. the total annual admissions of phthisis cases with the percentage death-rate; and in Table III. the total deaths from all causes and the death-rate from phthisis calculated from such total.

TABLE I.—*Total Number of Admissions under each Rating.*

Year.	Able-bodied seamen.	Firemen.	Engineers.	Cooks.	Stewards.	Officers.	Various.	Total.
1890	41	13	13	8	2	2	3	82

TABLE III.—*Total Deaths from all Causes, with Death-rate from Phthisis.*

Year.	Total deaths from all causes.	Percentage death-rate from phthisis.	Year.	Total deaths from all causes.	Percentage death-rate from phthisis.
1890	122	31·2	1901	130	23·8
1891	127	25·9	1902	142	21·1
1892	119	26·0	1903	113	27·4
1893	116	24·1	1904	125	29·6
1894	134	23·8	1905	116	14·5
1895	130	24·6	1906	136	22·0
1896	155	25·1	1907	144	24·3
1897	116	24·1	1908	127	22·0
1898	126	27·7	1909	100	20·7
1899	121	30·5	1910	123	17·8
1900	136	27·2			

On glancing rapidly over the foregoing tables, it will at once be apparent to anyone how great are the permanent disablement and loss of life from a preventable disease among a class of people who from the nature of their employment ought to show a very small percentage of deaths from such causes.

It is interesting to note with regard to the admissions that the total annual admission was at its highest in the years 1896–99 inclusive, and from that year onwards to 1910 the rate of admission has considerably and almost steadily decreased.

Classified according to ratings, the greatest number of admissions occur among the able-bodied seamen, among whom are included for convenience quartermasters, boatswains, ship's carpenters, and others who work on deck but are not classified under any of the other headings. The high admission-rate among the "able-bodied" may partly be accounted for by the fact that there are more sailors included in this than under any other heading, and it frequently happens that seamen of foreign nationality, unable to talk English, are admitted as sailors under this category.

Next come the firemen, and although the admissions among them are much less than in the preceding class, there is a very much greater incidence of phthisis among them than in any of the other succeeding classes—about equal, indeed, to the total of all the other sections put together. Stewards supply a greater percentage than cooks. Under the officer class are included first, second, and third mates and the captains. The rate among them is very small. Under the heading, "Various," are included stevedores, bargees, &c.

Death-rate.—It will be noticed that although the number of admissions has decreased the death-rate does not show a corresponding decrease. The highest number of deaths corresponds closely to the highest number of admissions, but the death-rate per cent. of total cases treated is highest in the years 1904–07–08. Comparing the actual number of deaths from phthisis with the total deaths from all causes, it will be seen that from one-fourth to one-sixth of the registered deaths are due to tuberculosis of the lungs. The highest death-rate per cent. calculated in total deaths from all causes occurred in 1890. The rate then slightly diminished until 1899, when it went up to 30, but since then it has kept below that figure.

To summarise the points brought out in the tables, it is seen that the number of admissions of cases of tuberculosis of the lungs has somewhat diminished during the last 10 years, but that the percentage death-rate out of the total numbers treated does not show a corresponding decrease, the highest figure, 47, occurring as late as 1907. This high death-rate is probably due to the advanced state of the disease in the majority of the cases before the patients seek treatment at the hospital. In the younger members of a crew who are admitted in a comparatively early stage of the disease the type is more often acute miliary tuberculosis, the course of which is very rapidly fatal.

If the crew of a ship were arbitrarily divided into two sections—viz.: (1) those who spend most of their time below deck, and (2) those who work for the most part on deck—it would be seen that tuberculosis is more frequent among the former than the latter. In the navy tuberculosis has decreased for the last 10 years. This is no doubt due to the fact that the conditions under which the sailor lives as regards sanitation and accommodation have vastly improved, and when cases of tuberculosis occur they are immediately invalided out of the service. In the merchant service there is still much room for improvement. Not only is there need of this in accommodation and ventilation, but the elementary principles of hygiene should, as far as possible, be instilled into the sailor and the danger of indiscriminate spitting brought before his notice by printed forms or otherwise. More stringent precautions also should be taken in that all subjects of tuberculosis should be discharged from the service, and no man who, on medical examination, shows signs of tuberculosis or gives a history of having suffered from it should be engaged for service on board ship.

But now comes the difficulty as to what is to be done with patients discharged as unfit for further service on board. Hitherto they have been allowed to drift about, and no provision has been made either in the navy or the merchant service by which the sufferers could be treated or given a chance to improve in health. Now that the National Insurance Bill includes the provision of State-aided sanatoriums, much good will be expected to accrue, but failing this it is high time that philanthropy extended its generous hand to provide a sanatorium exclusively for our sailors, on whom more than on any other members of the community the wealth and prosperity of the nation depend.

Seamen's Hospital, Greenwich, S.E.

A NEW THERMO-THERAPEUTIC METHOD IN GYNÆCOLOGICAL CASES.

BY S. FLATAU, M.D.,
NUREMBERG.

AGES ago the therapeutic instinct recognised the healing properties of warmth, and added them to its stock. But the employment of heat as a treatment, founded on scientific principles, dates from the time when August Bier collected, extended, and enlarged the earlier works of physiologists and pathologists in his system, "Hyperämie als Heilmittel."

As a matter of course the gynæcologists, too, were desirous of applying the advantages of hyperæmic treatment to their special branch, the accessibility of the female genitals favouring the introduction of heat. Finally, according to the researches of Goldscheider,[1] the abdomen seemed especially adapted to the stimulating properties of warmth on account of the numerous nerve endings susceptible to heat which it contains (Ruffini termini). We know, indeed, that warmth exercises an expanding effect on the vascular system and that the amount of blood in the skin operates on the neighbouring deeper-lying vessels in the sense of causing a more rapid exchange, a larger "turnover."[2] As a matter of fact, the abundant subcutaneous cellular tissue by its low conductivity (which was demonstrated by Fuchs[3]) forms a great obstacle to the penetration of heat when we desire to apply it only through the skin. But, on the other hand, by reason of the extraordinarily decreased speed of the blood in the pelvic nervous system, we may assume that the heat will not be too rapidly dispersed or lost, but that, on the contrary, it will accumulate. Moreover, the stimulating effect of heat-therapy increases, to a certain degree, with the degree of temperature and the duration of the application. It is on this hypothesis that thermo-therapy, in cases of pelvic diseases in women, must be built up.

But a long time passed before a useful and practical method, which was destined to receive widespread recognition in medical circles, made its appearance. Strictly speaking, the first applicable thermo-apparatus was that produced by Polano,[4] while working side by side with Bier and Klapp in Greifswald. In this apparatus hot air, up to a temperature of 100° C., was caused to circulate round the abdomen of the patient, the abdominal regions being isolated in a wooden case. But in spite of the excessive heat registered by Polano's thermometer, the

[4] Zentralblatt für Gynäkologie, 1901, No. 30.

temperature of the pelvic contents was very slightly affected, for heat which is applied to the skin penetrates it to only a very small extent. The subcutaneous tissues form a bad conductor. Furthermore, the perspiration which collects on the skin in large quantities, and with which the air in Polano's apparatus became saturated, formed another and still greater obstacle to heat penetration. If any hyperæmic result was produced in the interior of the pelvis it could only have been a very weakened, and if one may say so, a collateral, effect. Neither was the problem of raising pelvic temperature solved by the kataplasma ovens, heat boxes, and so-called thermophores, with highly saturated solutions of sodium acetate.

The early practical tests which I made in my private clinic were successful. During the application the pelvic contents were always raised several degrees in temperature—that is, the pelvic organs were really heated. My experiments were still more successful when the introduction of the instrument into the vagina was combined with an electro-thermophore which covered the abdomen (Fig. 2). Through the proximity of two hollow organs, the bladder and the rectum, we have a good opportunity to measure the increase of temperature and the influence of the heat introduced into the pelvis. Numerous measurements were made in this manner, and the temperatures were read on thermometers introduced into the bladder and rectum (after the latter had been cleaned by enema). Here I give the averages of a very large number of readings expressed in Centigrade:—

	After 1 hour.	2 hours.	3 hours.
Bladder	38·8°	39·8°	40·2°
Rectum...	38·5°	39·2°	39·8°

FIG. 1.

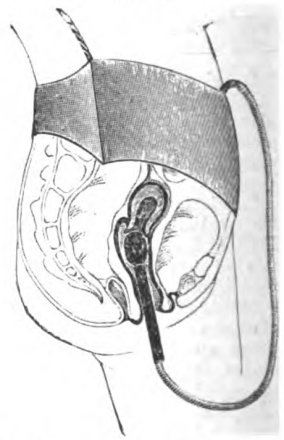
FIG. 2.



Semi-diagrammatic view of the introduction of a "Pelvitherm."

Other gynæcologists endeavoured to obtain direct results in the diseased genitals. Incessant syringing from a sort of thermophoric vessel [5] was also recommended. Stratz [6] and Baumgärtner [7] designed apparatus by which they claimed that vaginal washings up to 50° C. might be carried out without scalding the external genitals. Finally Walser and Pinkus produced an instrument [8] which proved to be serviceable.

But the results of all these methods of applying heat are feeble and evanescent. Even if 20 pints of hot water are passed through the vagina, still the rise of temperature in the pelvic organs is practically *nil;* and, moreover, the processes require too much attendance. Hence arose the idea of Mirtl [9] and Stehlik [10] to construct a thermophore in the form of a "colpeurynter" filled with "thermaphore" salts, which could be introduced into the vagina. Unfortunately, the heating effect in this case also was insignificant, and the stock of heat in the thermophore decreased continuously instead of remaining constant.

To produce a source of heat that should remain constant was the problem to be solved in heating the pelvis. Its practical solution was only made possible by the improvement in thermo-electric apparatus. When I first saw the electric thermophore cushions, as made by the firm Heinrich Stanger, in Ulm, a solution of the problem immediately occurred to me. I made out of silver-plated metal a thick hollow rod ending in a sort of bulb (see Fig. 1). Within this is a mass of asbestos powder, which is heated by passing an electric current through it. A small indicator makes it possible to increase or decrease the temperature with sufficient delicacy.

The mode of application is the simplest imaginable. My apparatus can be connected up to any switch terminals or any electric lamp which can be replaced by a screw contact, and using either a continuous or an alternating current. The regulation of the heat introduced, as shown by the indicator, is best attended to by the patient, whose safest guide is her own sensations. There is no deposit of perspiration on the abdomen; the heat is absolutely dry. We know that, objectively considered, dry and damp heat are totally different phenomena, and subjectively, too, are differently felt; and dry heat is more agreeable to by far the most patients. My patients bore the application in all cases excellently; on other parts of the body, especially the breast and head, symptoms of their perception of increased temperature appeared as well as perspiration. Although measurements taken under the arm showed no increase of temperature in the body as a whole, increased activity of the heart and lungs was observed, but this was not severe enough to cause the patient inconvenience. If the vagina and the cervix uteri are examined in a mirror shortly after treatment, marked hyperæmia and hyper-secretion will be observed.

The diseases in which the apparatus is indicated are numerous, although greater experience in more extended medical circles is necessary before drawing hard-and-fast lines. Chronic disease of the para- and peri-metrium, chronic catarrh of the uterus and Fallopian tubes, so-called chronic metritis, exudation remains, dysmenorrhœa without evident cause, amenorrhœa in cases of uterine atrophy during nursing, all have shown symptoms of improvement under thermo-penetration. Catarrh in the bladder of long standing has also been favourably influenced.

[10] Münchener Medizinische Wochenschrift, 1899, No. 27.

On the other hand, the method is out of place in treating cases where there is fever, and in all diseases of the annexa in which pus is present or may be expected to form, and in tuberculosis of the genitals. As is well known, the gonococcus is hypersensitive to high temperature,[11] and hence diathermal experiments in cases of infection with Neisser's diplococcus would probably be attended with success. Usually I apply the instrument to patients for three hours daily, although, of course, there is no reason why this duration should not be increased. The temperature of the pelvis falls very slowly after the instrument is removed, so that the tissues only assume their normal temperature after one or two hours.

I demonstrated my apparatus before the Franconian Gynæcological Society on Oct. 24th, 1908, and spoke, too, of the extent to which it might be employed.[12] This I wish to emphasise because the whole idea was evidently in the air during the development of our electrotherapeutic methods—I mean the idea of diathermia, the thermo-penetration of segments of the body (*vide* the works of von Zeynek, von Preyss and von Berndt, Klingmüller and Nagelschmidt.) Thus, Sellheim described, 18 months later,[13] a process in which the temperature of the pelvic organs was raised to 40° and 41° C. by passing the so-called high-frequency currents (de Forrest current) between two electrodes. For the present, however, there are two arguments against the general employment of that method. First, we still know too little concerning the physical and biological effects of the high-frequency current on the living tissues. Secondly, Sellheim's apparatus is much too dear. Its price ranges from £35 to £45, and only one patient at a time can be treated. The purchase of a number of Sellheim's apparatus for a large gynæcological department with moderate means would be in most cases an impossibility.

Next, Feis, in Frankfort, in ignorance of my first publication, announced his kolpotherm.[14] In this instrument a small electric lamp is enclosed in a metal case and introduced into the vagina. Compared to the fragile carbon wire and glass case in Feis's kolpotherm, my device has the advantage of being absolutely unbreakable, and can be used for an unlimited length of time.

I do not report a large number of cases, but I wish to make more generally known a method which I devised three years ago, and since then have thoroughly tested in my clinic and in private practice. To recapitulate: (1) This vaginal heating instrument, the "Pelvitherm,"[15] raises the temperature of the female pelvis up to about 40° C. for any length of time; (2) its use, in contrast to all other existing methods, requires no special superintendence, and therefore does not take up the time of the clinical staff; (3) it can be used anywhere where electric light is in use, including the patient's home; and (4) the instruments are so cheap and lasting that every hospital or private practitioner can procure a number of them.

A CASE OF MYELOID LEUKÆMIA WITH CHYLOUS ASCITES.

BY HAROLD S. FURNESS, M.B., B.S. LOND.,
AND
GEORGE F. STEBBING, M.B., B.S. LOND.,
ASSISTANT MEDICAL OFFICERS TO THE LAMBETH INFIRMARY.

THE patient, a man aged 40 years, was admitted to the Lambeth Infirmary on July 12th, 1909. He complained of swelling of the abdomen, which commenced in January, 1908. In February and March, 1909, he was an in-patient of St. Mary's Hospital, where the diagnosis of splenomedullary leukæmia was made. By the kindness of Dr. Reginald Miller we are able to give the following particulars of his condition at that time:—

There was a general enlargement of the lymphatic glands, the liver and spleen were enlarged, there was some free fluid in the abdomen, and the urine was normal. The condition of the blood was as follows: Hæmoglobin, 70 cent.; red cells, 5,600,000; and white cells, 1,800,000. A differential count of the white cells gave the following percentages: Polymorphonuclear neutrophiles, 47; myelocytes, 20; large mononuclears, 6; small mononuclears, 26·5, and mast cells, 0·5. The red cells showed some poikilocytosis and variation in size, and polychromatophilia; nucleated red cells were very numerous, nearly all normoblasts.

Three weeks before admission to the infirmary the swelling of the abdomen increased considerably, and the legs had been swollen for three and a half months.

On admission the patient was pale, very short of breath, and there were dilated venules on the face; the lymphatic glands were everywhere enlarged. On the left side of the neck was a discharging sinus where an abscess had been opened two years previously. The abdomen was distended and the legs were markedly œdematous; there were signs of free fluid in each pleural cavity. On July 14th the abdominal distension was relieved by paracentesis, 11½ pints of milky fluid being withdrawn. It was then easy to feel the enlargement of the spleen and liver. The spleen formed a hard rounded tumour in the left hypochondrium, and reached below the umbilicus; the surface was markedly rough. The lower limit of the liver was a hand's breadth below the costal margin. The removal of the fluid gave great relief at first, but the abdominal distension soon recurred, and the œdema of the subcutaneous tissues increased. On the 23rd 8 pints of ascitic fluid, having the same milky appearance as before, were withdrawn. The patient died suddenly on the 24th. The condition of the blood was as follows: Hæmoglobin, 65 per cent.; red cells, 4,500,000; and white cells, 326,000. A differential count of the white cells gave the following percentages: Polymorphonuclear neutrophiles, 41·6; myelocytes, 52·4; eosinophile myelocytes, 0·4; small lymphocytes, 2·8; large lymphocytes, 1·6; eosinophile leucocytes, 0·4; and mast cells, 0·8. A specimen of the ascitic fluid was examined by the Clinical Research Association, who reported as follows:—

A faintly alkaline opalescent fluid of specific gravity 1015, only moderately albuminous in character. The opalescence persists after prolonged centrifugalising, but is more or less cleared up by extraction with ether, and the ethereal extract is found to yield a moderate quantity of fat. The centrifugalised deposit from the fluid consists of leucocytes with a slight admixture of red blood corpuscles. The following are the percentages of a differential count: Myelocytes, 28; eosinophile myelocytes, 12; polymorphonuclear neutrophiles, 23; lymphocytes, 7; eosinophile leucocytes, 8; and mast cells, 22.

The urine of the patient was milky in appearance like the ascitic fluid, and also contained myelocytes and a large quantity of albumin.

On post-mortem examination free fluid was found in the chest and the abdomen; that in the abdomen had the appearance already described, and that in the chest presented the ordinary characters of a serous pleural effusion. There was marked perisplenitis, the capsule of the spleen being greatly thickened and adherent to the anterior abdominal wall and omentum. Sections of the liver, the spleen, and the kidneys showed very numerous leukæmic nodules, which had the usual appearance under the microscope. A section from a gland in the neighbourhood of the discharging sinus in the neck showed characteristic tuberculous giant cells and patches of degeneration.

The interest of the case lies in the presence of large numbers of myelocytes in the ascitic fluid and urine, the chylous nature of the ascites, and the extensive general enlargement of the lymphatic glands.

We are indebted to Dr. W. H. Willcox for the use of the notes taken at St. Mary's Hospital, and to Dr. M. H. Quarry for permission to publish the case.

Lambeth Infirmary, S.E.

UNIVERSITY OF BIRMINGHAM.—The Dean and Faculty of Medicine of the University will give a conversazione to inaugurate the opening of the session of the Medical Faculty of the University on Monday, Oct. 2nd.

VIEWING THE BODY.—The question of the juror's viewing the body at an inquest is perennially green. The Home Secretary has replied recently to the Wilmslow authorities, who addressed him in protest against the existing law, that he could not hold out any prospect of legislation at present. At Bolton the compulsory viewing of bodies has just been strongly protested against by several jurors, when the coroner said that the best course would be to pass a resolution framing their opinion, and forward it to the local Members of Parliament.

Reviews and Notices of Books.

Die Basedow'sche Krankheit. (*Basedow's Disease.*) Von H. SATTLER, Professor in Leipzig. Part II. From Graefe-Saemisch' Handbuch der Gesamten Augenheilkunde. Leipzig: W. Engelmann. Pp. 154. Price 6 marks.

THIS section of Professor Sattler's exhaustive contribution on exophthalmic goitre to the Graefe-Saemisch' Handbuch deals with a variety of questions in connexion with the affection. In Part I. the symptomatology of the classical or typical form of the disease was fully discussed.[1] Here attention is drawn to the various incomplete forms (*formes frustes*), in which one or more of the cardinal symptoms are absent through the entire period that a case is under observation, or, at any rate, during a very great part of its course. Of these forms there are one or two that call for more particular notice—viz., the so-called kropfherz (thyreotoxic cardiopathia), the struma basedowificata, and the "basedowoid" variety.

In cases of kropfherz, cardio-vascular symptoms, usually accompanied by tremor, a tendency to perspiration, and increased excitability, supervene upon a simple goitre that has existed for a longer or shorter period. In some these symptoms are, no doubt, due to mechanical causes, whether from pressure of the deap-seated goitre on the air-passages (whereby changes in the lungs, the pulmonary circulation, and the right side of the heart are produced), or on the great veins opening into the right auricle (the struma vasculosa venosa of Kocher), or in exceptional cases from pressure of the goitre on the nerves in the cervical region. The great majority of these cases, however, occur independently of any mechanical pressure, and it is to this class that the name thyreotoxic cardiopathia (thyreotoxisches kropfherz) is applied. This condition is most frequently met with in young girls; it is favourably influenced by the administration of iodides or preparations of thyroid gland, and may continue for years without developing into the typical form of the disease. It possesses, therefore, characteristics which distinguish it from other incomplete forms, and are of importance from the point of view of prognosis and treatment; from an etiological standpoint, however, it really forms a link in the chain of diseases with artificial thyroidism at one end and typical Graves's disease at the other, which are all due to the toxic influence of a specific pathological condition of the thyroid gland.

In struma basedowificata, sometimes called secondary Basedow's disease, one finds the typical symptom-complex of exophthalmic goitre grafted on a simple goitre of long standing, the exciting cause of the further development in such cases being some mental shock, infectious disease, or operative procedure undertaken for the goitre. In this group some of the symptoms of the typical form—e.g., exophthalmos—are not infrequently absent. The same symptoms may supervene in cases of malignant disease of the thyroid gland. It is difficult to account for their development in such cases. It is suggested that the growth of the tumour in the thyroid gland sets up changes of a similar character to those produced in it by other agencies, such as the application of X rays to a goitre, although it has been shown that the histological appearances of carcinoma of the gland, as well as of the metastatic growths from it, are sometimes in many respects similar to those found in the goitre of typical Graves's disease. In the "basedowoid" variety of R. Stern it is the wide group of nervous symptoms that are most pronounced, this condition being sometimes mistaken for neurasthenia. An attempt has been made to distirguish this variety as a separate entity from the classical type of exophthalmi goitre, because of the presence of some hereditary neuropathic taint in such patients, but such a distinction the author considers too arbitrary to be entertained.

In the chapter on the course of this eminently chronic affection reference is made to the acute form which it sometimes takes at different stages, the tendency to relapse, and the very rapid development of symptoms that is sometimes manifested where the cases run a short course and end fatally or, more infrequently, in complete recovery.

The discussion of the termination of the disease is one of interest. It is pointed out that statistics on the death-rate that have been drawn from hospital practice are misleading from the fact that it is chiefly the more severe cases that are admitted to hospital, while the great number of mild cases are seen only outside or, it may be, are sometimes not recognised; on the other hand, where the number of cases observed has not been very large, the inclusion of a few acute and fatally ending cases renders the percentage unduly high. Another source of error lies in the fact that few observers are able to follow the subsequent history of patients that have been discharged as improved or cured. An analysis of a wide range of cases recorded in the literature shows the mortality to be 11 per cent. As a general rule the danger of a fatal issue is proportional to the severity and acuteness of the case. The question of the proportion of recoveries depends on the strictness with which different observers regard such a result. This varies considerably, as is seen from the figures quoted by writers in different countries, and while a very large number of cases attain what may be termed a relative recovery, where the patients are free from any subjective symptoms and can resume their ordinary vocation, the author comes to the conclusion that complete and permanent recovery is very rare where the disease has existed for any length of time and the symptoms are numerous and well marked. Attention is also drawn to the various conditions, such as pregnancy, as well as gynæcological and intranasal operations, that have a favourable influence on the issue of this disease.

After a consideration of the order in which the various clinical symptoms may usher in this affection, the questions of age and sex are taken up. From an analysis of 3800 cases gathered from the literature and the author's own observation it is found that the proportion of females to males affected is 5·4 : 1, but it varies in different countries and in different parts of the same country. It is worthy of note that in England the ratio of incidence among females is very much higher; out of 13 writers in this country there are only three in whose series of cases the proportion between the sexes approaches that of the average above mentioned; in the reports of all the other writers, and especially in those in which large numbers are available, the preponderance of cases of the female sex is much more pronounced, the ratio in a total of 660 cases being 23 : 1. As regards the incidence at different periods of life, it has been found that out of 3477 cases where the age of the patients was recorded 184 have occurred before the sixteenth year; amongst these there is a relatively larger percentage of males than females. In the latter sex the greatest number of cases occurs between the sixteenth and fortieth year of life, and after the age of 45 the predominance of females affected becomes less, except about the menopause, when there is a slight increase. Amongst male patients most cases occur between the twentieth and thirty-fifth year, and after the forty-fifth year the percentage of males is appreciably greater than that of females—viz., 20 per cent., as compared with 14 per cent. for the latter.

The chapter on the characteristics of this disease in childhood brings out a number of interesting points on the general

[1] See THE LANCET, August 20th, 1910, p. 547.

resemblance of its clinical characters to those observed in adults, and emphasises the relatively mild form and course which it takes. The volume concludes with an account of the geographical distribution of Graves's disease—in which the variation in its frequency in various parts of the world is well brought out and comment on its prevalence in this country is made—the so-called Basedow diathesis, and the occurrence of the disease among the domestic animals. The bibliography is continued in this part and brought up to the end of 1909.

Handbook of the Surgery of the Kidneys. By W. BRUCE CLARKE, M.A., M.B Oxon., F.R.C.S. Eng., Senior Surgeon to St. Bartholomew's Hospital; formerly Surgeon to the West London Hospital and to St. Peter's Hospital for Stone and Other Diseases of the Urinary Tract; Member of the Council and of the Court of Examiners of the Royal College of Surgeons of England; formerly Examiner in Surgery to the University of Oxford. With 5 plates and 50 illustrations in the text. Oxford University Press: Henry Frowde. London: Hodder and Stoughton. 1911. Pp. 199. *Price 10s. 6d.*

MORE than 20 years ago Mr. Bruce Clarke was awarded the Jacksonian prize by the Royal College of Surgeons of England for an essay on the surgery of the kidneys, and ever since that time this department of surgery has had a special interest for him; and now, after this long interval, he has put into print the fruits of his experience of renal surgery. He acknowledges that some of the views he has put forward are at variance with those which are generally held, but the record presented in this book is a personal one, and he has referred to the views of others mainly when they differ from those which he holds. The book is not intended to be an encyclopædia of the progress of the surgery of the kidney, but rather a handbook for the busy practitioner and a record of the opinions held on this subject by a surgeon who has had ample opportunities for studying it very thoroughly.

The book commences with an account of the normal and the abnormal anatomy of the kidneys and ureters, and here we have a very simple account, without any unnecessary refinements, of the relations of the kidneys, so that it is easy for the reader to form a clear idea of the position of the organs and of the structures with which they are in relation. The second chapter describes the way in which a patient should be examined in order to ascertain whether there is anything wrong with the kidney, and the main conditions are indicated which have to be distinguished from enlargements of the kidney. The situation of pain due to disease of the organ is then considered, as well as the direction along which that pain may spread. The author speaks in favour of the use of a urinary separator for the purpose of comparing the urine from the two kidneys, but he refers also to such other methods as the methylene-blue test and the cryoscopic test. He mentions, however, that the latter test can only be carried out by a practised hand, and that it cannot be regarded as of any value in the daily routine of surgical practice, unless the surgeon is able to command the services of a skilled pathological chemist. In the chapter on operations on the kidney Mr. Bruce Clarke states that for the operation of lumbar nephrectomy he prefers to make the incision below and parallel to the last rib, and by the same incision he removes stones from the upper part of the ureter. He speaks with approval of an apparatus devised by Professor Watson of Boston, Massachusetts, for catching urine in the loin, either after the formation of a urinary fistula, or for cases in which the ureter is brought out into the loin.

In the chapter on wounds and injuries of the kidney the author mentions an important point in diagnosis—that renal injury alone is, in his experience, never associated with severe shock and a depressed temperature, and therefore the presence of shock following on an accident and coupled with a rapid fall of temperature is suggestive of injury of some other abdominal organ rather than of renal trouble. The author considers that if a moveable kidney causes no pain or inconvenience no treatment is needed, but if it is certain that the kidney is giving rise to symptoms an operation is needed, for he holds that belts are of little value. He performs Hahn's operation of nephropexy. An important chapter is that devoted to stone in the kidney and ureter; this is illustrated by a large number of skiagrams of renal stones *in situ*, and a very excellent skiagram from a case under the care of Mr. P. Furnivall shows even the laminated condition of the stone. Stress is laid on the need to distinguish shadows cast by stones from those cast by calcified glands or fæcal contents. Chapters on tuberculosis of the kidney and pyelonephritis follow. Mr. Bruce Clarke concurs in the opinion which is generally held at the present time that tuberculosis may be confined to one kidney for a long period. In the treatment of acute pyelonephritis due to the bacillus coli the author expresses great faith in the use of vaccines. The final chapter deals admirably with renal tumours.

We congratulate Mr. Bruce Clarke on the result of his labours; the one criticism which we offer is that some of the illustrations which are reproduced from photographs do not show clearly what they are intended to portray—for instance, Figs. 42 and 43; and better results would have been obtained if they had been re-drawn. The main characteristic of the book is its practical nature, and its value lies in the fact that it is likely to prove of service to the practitioner in his daily work.

Diagnostic and Therapeutic Technic: A Manual of Practical Procedures Employed in Diagnosis and Treatment. By ALBERT S. MORROW, A.B., M.D., Adjunct Professor of Surgery in the New York Polyclinic; Attending Surgeon to the Workhouse Hospital and to the New York City Home for the Aged and Infirm. With 815 illustrations, mostly original. London and Philadelphia: W. B. Saunders Company. 1911. Pp. 775. Price 21*s.* net.

MODERN methods of diagnosis and treatment of disease in all departments of practice involve the use of minor manipulative measures, the technique of which is taken for granted or but briefly considered in many text-books. Dr. Morrow, realising the importance of the details of many of these in regard to their effective or successful employment, has collected them in the book before us, and has described them simply and practically. He has illustrated his descriptions with copious diagrams, from which all unnecessary details are eliminated. In nearly every case the instruments used are figured, so that the necessary apparatus for each procedure can be seen at a glance. It is obvious that in regard to such matters dexterity can come only from practice, but clear descriptions, including practical hints, should be useful aids to the practitioner in applying these methods, which are becoming daily of greater importance, and in avoiding the dangers or disadvantages of limited experience, since in not a few instances the causes of failure are indicated.

The opening chapters deal with the administration of general anæsthetics and the production of local anæsthesia. Sphygmomanometry forms the subject of the next chapter, and several of the more commonly employed instruments are figured and their use is described. The technique of transfusion is then examined, and the details of various methods, including those of Crile and Carrel, are carefully explained and illustrated. The various ways of infusing physiological salt solution are next reviewed. A chapter is devoted to certain miscellaneous procedures, such as the hypodermic and intra-muscular administration of drugs, vaccination,

acupuncture, venesection, scarification, cupping, and leeching. The uses and methods of application of Bier's hyperæmic treatment are described; and sensible directions are given as to the manner of applying the method, the time for which it should be given, and the choice of cases for its employment. The collection and preservation of pathological material for microscopical or bacteriological investigation are next dealt with. The necessary apparatus is figured, the precautions to be taken are clearly indicated, and the manner of collecting and preserving the substances obtained is in every case clearly stated. Exploratory punctures and the aspiration of various cavities for therapeutic purposes are described in the detail that their importance demands. In aspiration of the abdomen for ascites the use of a straight or curved trocar with a diameter of $\frac{1}{8}$ to $\frac{1}{4}$ of an inch is recommended. Tapping by means of a long Southey's cannula and a fine rubber tube to facilitate drainage, which is often a very satisfactory measure, is not described.

The remainder of the book deals with the application of digital or instrumental methods to the diagnosis and treatment of the individual organs or regions of the body. Space will not permit us to enumerate all the various methods described, but they comprise many of the newer as well as the older procedures, and they are invariably given in sufficient detail to be readily understood and applied. The nose and accessory sinuses, the ear, the tongue and trachea, the œsophagus, stomach and intestines, urethra, prostate, bladder, kidneys, and generative organs are all separately considered. Among the methods described we may mention tracheobronchoscopy, œsophagoscopy, urethroscopy, cystoscopy, and catheterisation of the ureters.

Dr. Morrow's book is essentially practical and should be useful to the hospital resident and to the practitioner who wishes to employ up-to-date methods in diagnosis and treatment.

Nouvelles Méthodes de Sero-diagnostic. Syphilis, Mycoses, Kystes Hydatiques, Lèpre, &c. (*New Methods of Serum Diagnosis*) Par le Dr. ED. JOLTRAIN, Ancien interne des Hôpitaux. Préface du Professeur GAUCHER Troisième édition, avec figures, revisé et augmentées. Paris: A. Maloine. 1911. Pp. 254. Price Fr.4.

THIS book presents in convenient and intelligible form the general technique of the Wassermann reaction and of some of its many modifications, together with a clearly written exposition of the principles upon which they are founded and a review of their practical uses and of their limitations.

The general nature of immunity reactions is first briefly indicated, then some experiments upon the agglutination of the treponema of syphilis are described, and the fundamental facts in regard to hæmolytic reactions are outlined. Wassermann's method is described in full detail, with the manner of preparing and titrating the individual reagents necessary, and with a full account of the various controls essential to its proper performance. An interesting analytical and statistical study is given of its indications in regard to syphilis in all its stages, including the various forms of visceral lesions and the parasyphilitic affections. The influence of various therapeutic agents upon the reaction, such as mercury and organic forms of arsenic, is discussed. The results obtained by Wassermann's reaction with the cerebro-spinal fluid are compared with those afforded by the cytology of the fluid and by Noguchi's butyric acid test. The various non-syphilitic conditions in which a positive reaction has been obtained are discussed—namely, leprosy, scarlet fever, certain diseases due to spirilla and trypanosomes, and in some persons under narcosis. The application of similar methods to other affections, such as sporotrichosis, actinomycosis, hydatid disease, mycosis fungoides, and a number of infective processes, including pneumonia, Mediterranean fever, relapsing fever, tuberculosis, and leprosy, is also dealt with. Other serum reactions, including the opsonic index, the determination of antitryptic power, and the meiostagmine reaction, are also described, and the results obtained by them are briefly referred to.

Dr. Joltrain's book has reached its third edition, and merits the commendatory remarks bestowed upon it in Professor Gaucher's preface.

Hygiene for Nurses, Theoretical and Practical. By HERBERT W. G. MACLEOD, B.Sc., M.D., C.M. Edin., M.R.C.P. Lond., D.P.H. Lond. and Camb. With 49 illustrations. London: Smith, Elder, and Co. 1911. Pp. 233. Price 3*s.* 6*d.* net.

THE necessity of including lectures or instruction in hygiene to nurses generally at the hospitals, including those in London having medical schools, has apparently been overlooked as part of their regular training. Nurses certainly have to ventilate the wards and to see that the annexes, closets, and baths are kept in a clean state, but they do not receive systematic instruction in public health. The author of the work under review recognises the important rôle that hygiene plays in nursing duties, and he explains simply and concisely the more important facts in public health a knowledge of which is valuable to a nurse in her daily work. The information given will be found extremely useful to those who desire to obtain a certificate in hygiene from the various public bodies which grant them.

The methods of instruction adopted by Dr. Macleod are those employed by him as one of the lecturers to the Queen Victoria Jubilee Institute for Nurses, and his methods are thorough. Attention is directed to those sanitary laws of the United Kingdom useful to nurses, and some of the most recent regulations and by-laws of the Local Government Board and the London County Council are inserted. The information regarding the sick-room, ventilation, heating, lighting, water-supplies and fittings, and drainage is given at length, and should be of practical value to every nurse when treating a case in a private house. A table of the chief infective fevers, giving useful information, has been included. Food, milk, and personal hygiene are all carefully considered.

The author has, on the whole, confined a wide selection of subject-matter within narrow limits, and what has been written will be very helpful to those for whom it is primarily intended.

The Anatomy of the Brain and Spinal Cord. By J. RYLAND WHITAKER, B.A., M.B. Lond., Fellow of the Royal College of Physicians, Edinburgh; Lecturer on Anatomy, Surgeons' Hall, Edinburgh, and School of Medicine for Women, Edinburgh; Examiner in Anatomy, Royal College of Physicians, Edinburgh. With 36 plates comprising 103 figures, many of which are coloured. Edinburgh: Messrs. E. and S. Livingstone. 1911. Pp. 228. Price 5*s.* 6*d.* net. Fourth edition.

Dr. Whitaker is to be congratulated on the fact that this book, which he wrote originally in his student days, has now, after a rather long dormant period, appeared again in the shape of a fourth edition. The author's claims for the little book are, and always have been, exceedingly modest, for the work is intended merely as a first introduction to the study of the central nervous system. A simple outline is provided, and the author has resisted the temptation, which the demand for a fourth edition and an accumulated mass of modern literature must have furnished, to enlarge the aims and scope of the work beyond the limits of its present utility. As a simple outline it has already proved its worth. The present edition has fallen into line with the requirements of modern terminology, and it contains a large number of clear

and useful diagrams which should be grasped without difficulty by the student who for the first time attempts to follow the complicated maze of cerebral anatomy. The author is fortunate in steering a happy middle course between the avowed "cram" book and the detail-laden modern text-book. The sphere of usefulness filled by the former editions of the work should be equally well occupied by the present issue.

Kursus der Normalen Histologie. Ein Leitfaden für den Praktischen Unterricht in der Histologie und Mikroskopischen Anatomie. (Course of Normal Histology, being a Guide for Practical Instruction in Histology and Microscopical Anatomy.) Von RUDOLF KRAUSE, a.o. Professor der Anatomie an der Universität Berlin. Mit 30 Figuren im Text und 208 mehrfarbigen Abbildungen auf 98 Tafeln nach Original-Keichnungen der Verfassers. Berlin und Wien: Urban und Schwarzenberg. 1911. Pp. 441. Price M. 20; bound, M. 22 50.

THIS work is designed by its author to give his medical students a thorough practical training in histology by the simplest available means, and the preparations he describes are such that most of them can be made by the student himself. The author attaches the greatest value to the freezing method of section-making, and he uses the Schanze pattern of microtome and carbonic acid as the freezing agent, while, of course, not excluding other methods Rightly, he lays great stress on the importance of making drawings of the preparations themselves. To this end he has himself drawn and coloured 208 preparations, which are reproduced in 98 beautiful plates accurately drawn, which give a guarantee that the methods used by the author are most satisfactory.

After a short description of the microscope and the mode of using it (pp. 1–24), about 70 pages are given to general micro-technics, including methods of fixing, teasing, cutting, decalcifying, and staining sections. All this is on the usual lines. The special part is divided into three unequal sections, dealing with cells, tissues, and organs. A careful description is given of each plate—first the magnification employed, and then the method used is stated, e.g., "Liver Cell of Salamander. 1000. Sublimate 3 p.c. Freezing. Biondi solution," and so on throughout the volume. Plates 1–11 inclusive contain 34 coloured figures and deal with the structures and characters of cells and epithelium in general. Plates 12–32 (82 figures) give a beautiful series of stained examples of tissues, including blood. The chapter on blood might perhaps be expanded. The rest of the plates are devoted to the study of the various organs. The organs of the circulation, lymphatics, and spleen are dealt with in Plates 33–38 (13 figures); ductless glands, Plates 39–41 (6 figures); digestive organs, Plates 42–55 (29 figures); respiratory organs, Plates 56–58 (5 figures); urinary and reproductive organs, Plates 59–67 (20 figures); motor organs, including motor and sensory terminations of nerves and muscles, Plates 68–71 (7 figures); nervous system, Plates 72–85 (29 figures); sensory organs, Plates 86–92 (13 figures); skin and mammary glands, Plates 93–98 (11 figures). This summary shows approximately the range of subjects embraced in the illustrations.

There are a few omissions—e.g., parathyroids and the results of the Golgi method for gland structures—though, on the other hand, very full details are given as to the use of the *intravitam* method. There are relatively few examples of organs with the blood-vessels injected; thus there is no section of injected lung, thyroid, muscle, stomach, cerebrum, and so on. In the descriptive text, also, references to the actual sizes of the cells or parts are missing. Perhaps this is intentional, as the work deals with the practical instruction in microscopic anatomy, but size should not be excluded. We see that for elastic fibres the author uses the resorcin-fuchsin method and omits the well-known orcein stain.

The work as a whole is accurate and painstaking, while the methods are carefully selected and are such as have commended themselves to the author, and we are sure that they will prove equally satisfactory in the hands of his English *confrères*. We should note that in many cases the magnifying powers are higher than those ordinarily used in some medical schools in this country. We commend Professor Krause's treatise to histologists generally.

Abnormal Psychology. By ISADOR H. CORIAT, M.D., Second Assistant Physician for Diseases of the Nervous System, Boston City Hospital. London: William Rider and Son. 1911. Pp. 329. Price 5*s.* net.

THE study of abnormal mental phenomena is a part of human knowledge which should be undertaken only by such as have had adequate medical and scientific training and education. The general reader has a certain interest in the problems of human personality, in the subconscious mind and its workings, in the curious cases of loss of memory or hysteria that find their way into the public prints; and if his conception of these difficult matters is not to be hopelessly vitiated by imperfect understanding he must be willing to learn from someone who has devoted himself to work in this province how meagre is the basis of established fact on which facile hypotheses are all too readily erected. When the abnormal mental phenomena above referred to are made to include crystal-gazing, automatic writing, and other kindred topics, the need for scientific caution is the more pressing.

In this small volume from the pen of Dr. Coriat will be found a series of discussions on the phenomena of the subconscious life, on the emotions, dreams, sleep, hypnosis, as well as on such pathological conditions as losses and illusions of memory, splitting of personality, hysteria, neurasthenia, psychasthenia, and psycho-epileptic attacks. The principal work in this field is summarised, and personal observations and experiments are added. Dr. Coriat explains and illustrates with lucidity and aptness, and his book can be recommended to the physician and to the layman whose tastes lead them to desire to explore these fascinating by-paths of mental life. In some ways the book is rather unequal. In the chapter on illusions of memory and the sensation of "*déjà vu*," reference might with advantage have been made to the light thrown on the subject by a consideration of the symptomatology of lesions of the uncinate gyrus and temporo-sphenoidal lobe. In the paragraphs dealing with what the author calls "psycho-epileptic attacks," he does not draw very clear distinctions between hysterical fits, psychic equivalents of true epilepsy, and such "functional" conditions as vaso-vagal attacks, the latter of which are frequently associated with marked psychical disturbances. Dr. Coriat gives due attention both to Janet's and to Freud's theories of hysteria and psychasthenia, but the reader is not enlightened as to their relative merits or demerits. As a whole, however, this little book contains much material not often brought within such small compass, and it may be read with pleasure and profit.

Recent Advances in Hæmatology, being the Dr. James Watson Lectures for 1910. By WALTER K. HUNTER, M.D., D.Sc. Glasg. With a coloured plate. London: Henry Kimpton. Glasgow: Alexander Stenhouse. 1911. Pp. 119. Price 5*s.*

IN this volume the author has reissued in book form the Watson lectures delivered by him before the Royal Faculty of Physicians and Surgeons of Glasgow in 1910.

The first lecture is devoted to the consideration of the blood itself, and in it are fully pourtrayed the matters

connected with the specific gravity, the alkalinity, the coagulation, the viscosity, and the cryoscopy of this tissue. The questions concerning the fat in the blood and the spectroscopic examination of the latter are next considered. The criticisms of the writer on these points are of much value. For example, he points out the small clinical importance to be attached to the estimation of the specific gravity, inasmuch as this is, speaking generally, an estimation of its hæmoglobin, whereas this can be measured more accurately by the hæmoglobinometer. Critical remarks will also be found concerning the question of the coagulation of the blood. This lecture concludes with an account of the various forms of red and white corpuscles, and it is illustrated by an excellent coloured plate.

The second lecture deals, first, with the origin of these corpuscles, as well as their mode of production, the two tissues chiefly concerned being the bone marrow and the lymphatic glands. The author then proceeds to pass in review some of the recognised diseases and disorders of the blood, and to place before his readers the present position of our knowledge as regards their etiology and pathogenesis. In this lecture will be found the facts related to secondary anæmia, chlorosis, splenic anæmia, kala azar, and infantile splenic anæmia. An interesting point narrated is the disappearance that is going on in America of chlorosis, there not being in that country nearly so many cases as there were five or ten years ago.

In the last lecture the author deals with the various forms of pernicious anæmia, paroxysmal hæmoglobinuria, splenomegalic polycythæmia, enterogenous cyanosis, leukæmia, purpura, hæmophilia, and scurvy. The section dealing with the subject of pernicious anæmia is one of the best in the book; the author makes five groups of this affection, as he rightly states that as yet there is no settled agreement as to what shall constitute the boundaries of this disease. He appears to favour the view that scurvy is a disease infective in origin. This view was also put forward some few years ago by Coplans in South Africa,[1] but the arguments in its favour are not very convincing.

This small volume concludes with an appendix wherein are described the various methods connected with the fixing and staining of blood-stains. The lectures will be found of great value to those who are interested especially in hæmatology, and Dr. Hunter has done wisely to issue them in volume form.

Some New and Interesting Points in Ships' Hygiene. By W. MELVILLE DAVISON, M.B., B.S., Medical Superintendent of the Booth Steamship Company, Limited. Bristol: John Wright and Sons. 1911. Pp. 87. Price 4*s.* net.

THE short title of this book is misleading, but the full title accurately describes the contents. It is not a book on ships' hygiene; for instance, there is nothing said about the ventilation, the drainage, the furnishing, the painting, the storage of food-supply, the cubic space per inmate, and many other problems affecting the health of those who live on board. But the book is valuable because practical and interesting in the account given of what can be done in regard to the new requirements that very recent discoveries have proved to be necessary. Perhaps the oldest of these comparatively new requirements is the killing of rats. Attempts have always been made to deal with rats, if only for the sake of saving the cargoes; but now that they are recognised as plague-carriers the rat grievance has become a much more serious matter. With the fleet of the Booth Line at his disposal Dr. Melville-Davison has made experiments on a very large scale with a rat-killing virus. The story of these experiments is remarkably interesting, for it was found that while the rats had become immune to the disease conveyed by the virus, the immune rats acted as disease-carriers to other rats that had not attained immunity. The rat problem, though not absolutely solved, can be mitigated, it is claimed, to the extent of 80 per cent. This would be worth effecting, not only as a measure against plague, but on financial grounds. It is calculated that the total annual damage to British ships done by rats amounts to £262,500. By the use of the virus this, it is suggested, might be reduced to £52,500; but there would be the cost of these operations, estimated at £13,125. Deducting these two sums from the loss usually experienced, we would have a net annual saving of £196,875.

The danger of mosquitoes and vermin as disease-carriers is also a recent discovery, and the little volume before us deals extensively with the practical means of getting rid of these pests. Not only is there given a full scheme of so constructing the port-holes, the ventilators, and the doors that mosquitoes cannot get inside a ship, but the authorities of the Booth Line have availed themselves of their medical officer's suggestions and built their new ship *Hildebrand* on these principles. All who are interested in sanitation at sea will congratulate the company on their enterprise, which should enable us to take a voyage to the Brazils with much less risk of contracting yellow fever, and with better prospect of enjoying a quiet sleep at night, even in the tropics. The suggestions made in regard to cockroaches call for very full research and experiments. This insect, it appears, carries numerous parasites, and cases of beri-beri have occurred at sea where there was no contact with other cases, but cockroaches had been found in the rice which the patients had eaten. There is much that is new and suggestive in this volume.

LIBRARY TABLE.

British Rainfall, 1910. By H. R. MILL, D.Sc., Director of the British Rainfall Organisation. London: Edward Stanford. 1911. Pp. 440. Price 10*s.*—All students of Nature and scientific observers will join in congratulating Dr. Mill on the completion of the fiftieth annual volume on British rainfall, which now contains the records of 4874 observers, this being a net gain of 190 over the previous year. The organisation is now vested in a body of trustees, but the available funds are not sufficient to carry on the work, a deficiency of £142 having had to be met by the director. The principal novelty in the present report consists in a rearrangement of the rainfall stations. When Mr. Symons commenced the publication of the annual volume in 1863 he adopted "with considerable hesitation" a classification of the stations by counties. Dr. Mill has now grouped them according to the river basins in which they are situate, this being the only satisfactory method from the standpoint of physical geography; but as for practical purposes the division by counties could not be abandoned, each county has been divided by watershed lines, so that the "river divisions" can be built up either into counties, or into river-basins, as desired. The mean rainfall for all stations in England in 1910 was 35·98 in., being 11 per cent. above the average of 35 years; in Wales it was 53·50 in., or 16 per cent. in excess; in Scotland, it was 46·46 in., or 3 per cent. above; and in Ireland 44·23 in., or 8 per cent. above the average. The wettest place in the kingdom was Llyn Llydaw, Snowdon. Here 187·06 in. were registered; in England, at the Stye, Cumberland, 144·40 in. fell; in Scotland, 145·45 in. fell at Laon, Loch Quoich; and in Ireland, 83·30 in. fell at Lough Caragh. The least rainfall, 19·44 in., was registered at Stockton, in Durham. In

[1] See Notes from South Africa, THE LANCET, Sept. 9th, p. 801.

discussing the rainfall of 1910 as compared with the yearly rains during the 30 years since 1881 three points of interest are brought out: (1) this was the first wet year for the British Isles as a whole since 1903, and with the exception of that year and of 1900 it was the wettest since 1882; (2) the years 1909 and 1910 have been the first instance of two consecutive wet years in England and Wales since the long run of wet years ended in 1883; and (3) the succession of one wet year following two dry years, which has been repeated in England and Wales seven times without a break from 1889–91 to 1907–9, has at last broken down. This seems to point to the approaching close of the long period of preponderating dry years, from which forecast agriculturists and others may derive some consolation for the abnormal conditions of the present summer.

JOURNALS AND MAGAZINES.

Edinburgh Medical Journal.—So far as original matter is concerned the greater part of the September issue of this magazine is occupied by a lengthy communication from Professor J. Rutherford Morison on the subject of intestinal obstruction. The author gives notes of 39 cases treated by him during 1910. He points out that whereas the results obtained in recent years in cases of chronic obstruction are far better than those of an earlier date, in the case of acute obstruction little advance seems to have been made. Here the most essential point is early diagnosis with immediate operation, while the technical skill demanded is not so great. Mr. J. Hogarth Pringle records in a clinical note a case of aneurysm of the third part of the left subclavian artery treated by aneurysmorrhaphy.

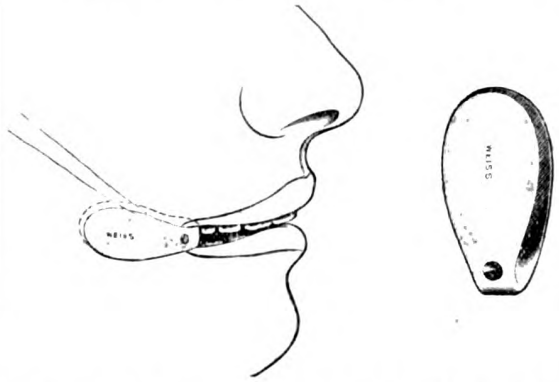
The Dublin Journal of Medical Science.—Lady Aberdeen's presidential address to the recent Health Congress in Dublin is published in the September number of this journal. In it her Excellency draws attention to the importance of enlisting the interest and gaining the assistance of the mothers of the country in the cause of sanitary progress, and accordingly points out the need for courses of instruction in such matters in the scheme of education adopted for girls of all classes. Dr. J. H. Woodroffe writes on the pupil and its reflexes in health and disease, and Dr. A. F. B. Shaw on Artificial Eruptions, under which title he deals with eruptions due to drugs and allied agents rather than with factitious lesions of the skin.

The Medical Chronicle.—In the September number of this magazine there appears a dissertation by Dr. J. Stirling Young embodying the results of much careful observation on the histology of the ovary. He treats first of chronic ovaritis, and finds that there does not exist a chronic idiopathic or primary ovaritis apart from syphilis and tuberculosis, all other inflammatory conditions of the ovary being secondary to uterine or tubal disease. In the second part of the paper he gives an account of the fat and fat-crystals occurring in the ovary. Dr. T. Wardrop Griffith writes on the changes found in the bones in a case of Raynaud's disease, which took the form of interstitial absorption of the terminal phalanges with ankylosis of some of the joints.

New Inventions.

TONGUE SUTURE GUARD.

ANY surgeon who has had occasion to perform certain operations upon the mouth, and especially removal of the tongue, must have been faced with one serious difficulty—a difficulty not during the actual operation, but following it. Unless the base of the tongue is kept forward for some days, there is a serious danger that it may fall backwards over the epiglottis, and respiration become seriously embarrassed, if not imperilled. To avoid this it is the custom to pass silk sutures, one on each side, through the base of the tongue which, being left long, are brought out of the mouth and knotted over the ears. These sutures after a short time act as a string saw over the oral commissures, and produce great



irritation at these points; they may even, if left long enough, cause slight ulceration of the commissures, and thereby much discomfort to the patient during the time they need to remain. In order to obviate this most surgeons pass these threads through rubber tubes which project somewhat both inside and outside the mouth. These tubes certainly obviate the "string saw" action, but it is very difficult to retain them at the point where they are required unless ceaselessly watched. They slip along the retaining threads and therefore are often entirely inside or outside the mouth. In either case they cease to be a protection to the commissures, and should they slip inside may add, by their presence, considerably to the patient's discomfort. A reference to instrument catalogues fails to discover any alternative appliance, and therefore I have designed these mouth clips which fit over the commissure on each side and permit the threads to pass through a hole in the solid base which projects slightly between the lips. These cannot slip either into or out of the mouth.

They have been made admirably for me by Messrs. Weiss. Though intended for the average thickness of lip, since they are made of celluloid, they can be moulded to any size of lip after steeping in boiling water. In the use of these guards the combustible nature of celluloid must be borne in mind, and no naked light must be allowed near to the patient's mouth.

Manchester. E. STANMORE BISHOP, F.R.C.S. Eng.

WOODEN CASE FOR LIGATURE JAR CONTAINING IODINE SOLUTION.

THE boxwood cases with screw-down caps having repeatedly given me trouble, owing to the failure of the threads to bite, I have had made for me by Messrs. Allen and Hanburys, Limited, of 48, Wigmore-street, London, W., a case of soft wood, which has the advantage of lightness. The stopper is a plain plug with sloping slides which wedges into the neck of the case. This does away with the screw-down cap. Before placing the jar in the case a string should be tied round the neck of the jar, the ends of the string lying on the lid of the jar. Without such string there may be a little difficulty in lifting the jar out of the case.

Plymouth.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 23, 1911.

Cerebro-spinal Fever and Acute Poliomyelitis.

IN THE LANCET last week we published from a local correspondent an account of outbreaks of "spotted fever" and acute poliomyelitis which have occurred recently in Devonshire and Cornwall. The epidemics have not yet ceased. At a meeting of the Devon county education committee on Sept. 8th Mr. G. ADKINS, the county medical officer, gave an account of the outbreak of acute poliomyelitis in various parts of the county. He stated that 25 schools had been closed, and that the disease was present in 12 out of the 52 districts of the county. There had been 80 cases altogether, and 16 deaths had occurred. A number of children were permanently paralysed. He also stated that three definite cases of "spotted fever" were known amongst those reported. As was obvious from our article on Sept. 16th some difficulty in the public mind appears to have arisen in diagnosis. Thus it is stated that at South Molton a child is supposed to have died from spotted fever on August 12th, and a boy, aged 15 years, taken ill on August 28th, died from acute poliomyelitis on August 30th. Until recent years very little attention has been drawn to epidemic cerebro-spinal meningitis, and still less to acute poliomyelitis. The use of synonyms has tended still further to confuse the diseases. Cerebro-spinal fever is also known as epidemic cerebro-spinal meningitis, malignant purpuric fever, petechial fever, and spotted fever; whilst acute poliomyelitis has also been designated acute anterior poliomyelitis and acute polio-encephalitis, a wealth of nomenclature that may well have led to confusion.

It is therefore of the highest importance that medical practitioners should have clear ideas as to the nature and principal symptoms of these two diseases. Cerebro-spinal fever, or epidemic cerebro-spinal meningitis, as its name indicates, is characterised pathologically by inflammation of the cerebro-spinal meninges, and the pathogenic micro-organism is now generally considered to be the diplococcus intracellularis of WEICHSELBAUM. Unfortunately, from the point of view of diagnosis, its clinical course shows great irregularity, the symptoms varying in different epidemics and in different cases of the same epidemic. The main phenomena are: fever of sudden onset, with much depression, pain in the head and neck, retraction of the head, and frequently delirium and coma; the temperature is irregular and variable, and a rash may or may not be present. The duration of the attack also varies greatly—from two or three days to three or four weeks or more. Attention has rightly been drawn to the cutaneous conditions. Herpes occurs with great frequency; but a petechial rash, which has given the name of "spotted fever" to the disease, is not at all constant, and cannot be relied upon for diagnosis. For the accurate recognition of the malady lumbar puncture is of considerable value, the cerebro-spinal fluid being examined for the causal organism. Joint affections are not uncommon, the joints being painful, red, and swollen; and some authors have described paralysis of the lower extremities which may persist for some time, but such a sequel is apparently rare. Acute poliomyelitis occurs usually among children, and is characterised by sudden complete loss of power in one or more limbs, followed by wasting of the paralysed muscles, and the growth of the bones of the affected limb is arrested. The distribution of the paralysis is very variable. Fever is usually present, the temperature rising to 101°, sometimes to 103° F. Pain may be complained of in the early stages, localised in the back, body, and limbs. The onset is sometimes very severe, the child becomes delirious and stuporous, and the head and back may be retracted, thus possibly giving rise to mistakes in diagnosis. The rapid occurrence of the paralysis and subsequent wasting of the limbs, however, serve to identify the complaint. The chief pathological changes are found in the grey matter of the anterior horns of the spinal cord. In the more severe cases there is a diffuse meningo-myelitis and encephalitis. The bacteriology of the complaint has not been definitely settled, although various observers have claimed to have isolated certain micro-organisms. Some authorities consider that the pathogenic agent belongs to the group of filterable and ultra-microscopic viruses.

The mode of spread of these diseases has been much discussed, and some interesting observations were mentioned in our article as the outcome of the observations of Mr. H. M. BODY, medical officer of health of South Molton. Cerebro-spinal fever seems not to be directly contagious, and is probably not transmitted by clothing or the excretions. It is rare to have more than one or two cases in a house, and in a city epidemic the distribution of the cases is quite irregular. With acute poliomyelitis the evidence of direct contagion is stronger, and numerous instances have been recorded in which children have contracted the disease after moving into tenements where other children had died from the affection. It has also been demonstrated by some observers that the virus of acute poliomyelitis is eliminated by the naso-pharyngeal mucosa. Mr. BODY has stated his opinion that it is possible for a healthy individual to act as carrier, and to convey the disease several miles to someone else. Dr. JOSEPH S. NEFF[1] made an interesting study of the cases of acute poliomyelitis occurring recently in Philadelphia. He believes the disease to be mildly contagious, but much less so than the other so-called children's diseases. He shows, however, that general sanitation, crowding, and housing conditions do not play such an important part in the spread of the disease as in other contagious diseases. In his memorandum he indicates by means of a map the location of cases in Philadelphia in the last epidemic of 1910, and as an interesting comparison he gives another map showing the location of cases of cerebro-spinal fever, which exhibit a similar distribution. In connexion with this disease, also, sanitary environment was demonstrated not to be a dominating factor in its etiology. We have only attempted

[1] International Clinics (1911), Twenty-first Series, vol. i. p. 70, et seq.

to give a very brief epitome of some of the characteristics of these two conditions, but we trust we have sufficiently indicated that it is important not to confuse the diagnosis, since cerebro-spinal fever and acute poliomyelitis are two distinct diseases with a different pathology and etiology.

Some Lessons from the Quincentenary of St. Andrews University.

THE committee in charge of these high celebrations may be congratulated on its complete success. To have assembled and entertained in a provincial town so numerous a company of guests, representing seats of learning and scientific associations from the Old World and the New, was no ordinary task. True, there were the guiding precedents of Edinburgh in 1884, of Glasgow in 1901, and of Aberdeen in 1906, but these were less prolific in warnings against failure than in successes to be equalled or surpassed, and it is to the credit of the smallest and least opulent of the four that she has even improved on the standard created by her sisters. The intellectual entertainment was in keeping with the social; and certainly the discourses of the Chancellor, Lord BALFOUR OF BURLEIGH; of the Lord Rector, Lord ROSEBERY; of the Vice-Chancellor, Principal Sir JAMES DONALDSON; and of the ex-Lord Rector, Mr. A. J. BALFOUR, were sufficient of themselves to have retrieved any shortcoming or misadventure in the arrangements. There was no excess of eulogy on the part of these orators; they were too experienced as men of the world, or as responsible holders of office, to betray the optimism so apt to appear on such occasions. The retrospect of Scotland's "Mater Studiorum," however honourable to her energy and perseverance in carrying out her ideal amid circumstances so adverse, was simply taken to encourage a further display of these qualities, and one and all of the said orators lost no opportunity of driving home the truth that with universities, as with individuals, the real test of merit is their power to progress.

Lord ROSEBERY, as the Mentor chosen by the students, did not fail to remind them of what has been a traditional defect in Scottish academic education—the want of thoroughness in mastering the subjects set for graduation—a defect described in characteristic fashion by Dr. JOHNSON as consisting in a taste of everything and a full meal of nothing. "A diluted omniscience" was Mr. FROUDE'S impeachment of the Scottish curriculum in Arts, his ideal being that of MARK PATTISON in his famous essay on "Oxford Studies," to teach the student "to know what knowledge of a subject means." This ideal has often been attained with exceptional approximation to success by the two great English Universities, Oxford and Cambridge, whose defaults in other directions are perfectly obvious, but whose practice has been that of restricting the subjects for graduation so as to admit of the students coming at least within measurable distance of knowing what mastery of them means. The practical result of the system has been to make Oxford and Cambridge the nursing mothers of pre-professional culture, insomuch that north of the Tweed, when an academic chair of Greek, of Latin, or of Mathematics, pure or applied, has to be filled, the electors frequently go to the two elder English Universities for the fittest candidate. A degree in Arts acquired by those attaining to the thorough standard implied in "the knowing what knowledge of a subject means" reacts for good on their subsequent profession, whether in the Church, or in the Law, or in Medicine. The last generation, indeed, has witnessed a departure from the old-fashioned thoroughness, but whether to the advantage of the graduate or to the formation of a more complete professional mind may well be doubted. Premature specialisation threatens to take the place of the former solidity—a specialisation *motivé* by the struggle for professional existence, and tested by examination, often competitive—the preparation for which has called into being the crammer, and the text-books so compiled as to enable students to score "marks," or, in familiar parlance, to get up the knowledge that pays. Science in tabloids is the outcome of the innovation, evoking from Lord ROSEBERY, in an effective passage of his brilliant address, the reproach of our being a "spoon-fed generation."

A point raised, this time by Mr. A. J. BALFOUR, in a speech which was in some respects the most striking of the series, was the function of science in discovering new sources of material energy in the more than probable event of our present resources failing. "We do not realise," he said, "the magnitude of the growth of knowledge that has taken place in the 90 years drawing to a conclusion." Our whole view of the world has been revolutionised in that time, and not only our whole view of science, but our whole view of history, of progress, and the development of mankind. With this progressive advance are we to assume, with the author of the "Novum Organum," that the moral world will not keep pace? Will there be no emergence of a better understanding between the members of the human family, a sense of brotherhood supplementing a sense of citizenship, and making for the peace of the world and the settlement of international differences, not by war, but by arbitration? The forecast seems to justify an answer in the affirmative, when

> "Mind and soul according well
> Will make one music,"

to which the march of humanity will keep time. For this, as for the goal at which all learning and all professional work ought to aim, the universities at home and abroad must combine and mobilise their energies until results, even provisional results, are attained as superior to those we now witness as were the semi-savage conditions of the university life of St. Andrews 500 years ago compared with those that have earned the congratulation of the world at her academic symposium so happily organised and carried out.

A Study of Psychopathic Heredity.

IN every department of scientific inquiry observation is inevitably influenced in greater or less degree by the doctrinal attitude of the observer, who cannot possibly avoid making an involuntary selection of data. However conscientious he may be in scrutinising the phenomena which he has to investigate, he will attach his mind to facts and aspects of facts which have an obvious bearing on the theory that he advocates, whether as supporting it or as contradicting it, while he will neglect or overlook other facts because

they have no such claim on his interest, and are therefore easily passed over as insignificant. But theories are often ephemeral and always imperfect, and the data which, being irrelevant to the theory of to-day, are ignored as of no account, may be vitally important to the theory of to-morrow, and their omission from the records of observation and experiment may in this way render valueless the result of years of laborious research. So true is this that from certain points of view it would hardly be a paradox to maintain that the value of a hypothesis is to be measured, less by the extent of the truth that it illuminates than by the small amount of the truth that it obscures; some bias it must inevitably give to observation, and what we have most insistently to require is that this bias shall be as slight as possible. If this test could be applied to the theories of heredity which divide the biological opinion of the day, probably its most hostile critics would admit that the doctrines associated with the name of MENDEL can claim to be free from this vice of distorting and narrowing our vision. For it is implicit in the Mendelian method, requiring as it does a high degree of minuteness of detail in the data on which it works, that it should collect its facts in a more complete form and with a more rigorous care for accuracy than can be expected, for instance, from the method of mass statistics, in which quantity is of more importance than quality. For this reason, and quite irrespective of the ultimate validity of the theory, we may anticipate that the application of the Mendelian analysis to the study of the heredity of mental disease will exercise a salutary influence in increasing the extent and precision of our knowledge of this most difficult and complex problem.

As evidence of what is already being done in this direction reference may be made to the excellent work which is being carried out by the Eugenics Record Office,[1] established last year in connexion with the Eugenics Section of the American Breeders' Association, and controlled by Dr. C. B. DAVENPORT. It is the object of this office to act as a clearing-house for data concerning "blood lines" and family traits in the United States; and so far as can be judged from the bulletins which it is issuing its organisation for these purposes is admirably planned. One of the specially commendable features of the method adopted by Professor DAVENPORT and his pupils is the employment of biologically trained investigators, technically known as "field workers," to collect the data for the pedigree charts. It is the business of these investigators to trace out all the living members of each family, to interview them, their friends and neighbours, and their medical attendants, and in this way to get a detailed and adequately controlled record of the family history. A large number of observations made under these stringent conditions have now been brought together, and it is claimed that they go to show that the facts of psychopathic heredity can be satisfactorily interpreted on Mendelian laws. This view has been most fully developed in a preliminary paper by Miss GERTRUDE CANNON and Dr. A. J. ROSANOFF, based on the family histories of 11 patients in the King's Park State Hospital, New York. The pedigrees include 35 distinct matings with a total of 221 offspring, and details have been obtained regarding practically every individual on the charts. For the purposes of the analysis of these details the writers assume that we may establish an absolute separation between normal individuals and individuals presenting what they call the "neuropathic make-up." This latter term appears to be of rather comprehensive character, for it is stated that "we find as manifestations of the neuropathic make-up in closely related persons cases of feeble-mindedness, convulsions in childhood from trivial causes or chronic epilepsy, cases of grave hysteria, various eccentricities, cases of dementia præcox, manic-depressive insanity, paranoiac conditions, involutional psychoses, and the like." This is a position which is somewhat open to criticism, for, though it will not, of course, be disputed that the different clinical varieties of degenerative insanity are probably fundamentally identical in nature, the inclusion in the neuropathic group of such ill-defined conditions as "feeble-mindedness" and "eccentricity" tends to make the limits of the group vague and arbitrary. Possibly this objection will be found to have less force when the pedigrees are accompanied by the detailed account of the conditions noted in each individual, whether assigned to the normal or to the psychopathic class. If this is so, and if we may accept the diagnoses made by the writers, then the pedigrees, so far as they go, will certainly bear out the contention that the insane taint does appear to be transmitted in a way that corresponds to the Mendelian laws. The first point to be noted when the pedigrees are examined in this light is that while there are a number of instances of neuropathic children born of normal parents, there is not a single instance of a normal child born of parents both of whom are neuropathic. The inference that a Mendelian would draw from this is, we believe, that if the condition underlying the various forms of the neuropathic make-up is a unit character, then it is recessive to normal. It can only be manifest, therefore, in an individual who has failed to inherit the dominant character of normality from either parent; and as such an individual cannot transmit what he does not possess, when mated with another neuropathic individual, he should have only neuropathic children. The normal individual, on the other hand, may have inherited normality from both parents, and, therefore, be pure-bred to that quality, in which case his mating with another pure-bred normal should yield only normal children; or his inheritance of normality may have been one-sided, and he may be carrying the psychopathic trait as a recessive, being thus hybrid with reference to the character of normality, and he should then be capable of transmitting the neuropathic make-up to his offspring. Now, not only are these general theoretical expectations realised in the pedigrees studied by Miss CANNON and Dr. ROSANOFF, but even the numerical proportions of normal and neuropathic offspring in the intermarriage of the several types must be allowed to approximate to what the distribution should be according to so-called Mendelian principles. Take, for instance, the mating of two normals, both of whom

[1] Eugenics Record Office, Cold Spring Harbour, N.Y., Bulletin No. 1. Heredity of Feeble-Mindedness, by Henry H. Goddard, Ph.D.; No. 2, the Study of Human Heredity, by C. B. Davenport, H. H. Laughlin, D. F. Weeks, M.D., E. R. Johnstone, and H. H. Goddard; No. 3, Preliminary Report of a Study of Heredity in Insanity in the Light of the Mendelian Laws, by Gertrude L. Cannon, A.M., and A. J. Rosanoff, M.D., 1911.

are hybrid as regards this character of normality. The pedigree charts show seven matings of this sort, with a total of 54 offspring. Theoretically, according to the principles, one-fourth of these children should be neuropathic, one-half normal but capable of transmitting the neuropathic make-up to their progeny, and the remaining one-fourth normal and not capable of so transmitting it. The actual results found are: 12 children neuropathic, 6 normal with neuropathic offspring, 10 normal with normal offspring, 18 normal without offspring, and 8 who died in childhood. This is a correspondence with Mendelian expectations which is sufficiently striking when it is borne in mind that the conditions with which we are dealing are such as must to some extent be susceptible to disturbance by environmental causes.

These results are remarkable, and their confirmation would be most desirable. If they stand further investigation they should exercise an influence on our views of insanity both in its medical and in its sociological aspects, so that it is reasonable to expect that the authors will lose no time in publishing the detailed notes of the cases included in their pedigree charts. We may then pretty confidently anticipate that there will be no lack of control observations to support or to invalidate their conclusions. If it should prove to be the case that the facts of insane heredity are susceptible of any Mendelian analysis, even though it be to a more limited extent than the authors of this interesting paper would have us believe, then the gain would, from a practical point of view, be very great. Hitherto, in dealing with this question, we have perforce been content to take our statistical material in the lump and to calculate from it a general average measure of the hereditary factor in insanity; we have had no grounds for formulating a definite opinion as to the likelihood of the transmission of an insane taint in individual cases. The Mendelian, on the other hand, if the promise of these investigations is made good, should be able to tell us with some approach to precision the probable results in each given instance of the mating of members of neuropathic stocks, and should thus be able to point the way to the elimination of the morbid trait. The prospect opened up by this new application of biological theory seems almost too roseate to be more than a mirage; but before we reject it as fantastic we may do well to consider the brilliant results which the same methods have won in other fields—results which, as Professor BATESON justly urged in his interesting address at the Portsmouth meeting of the British Association, should be an earnest of greater achievements to come. At all events, to return to the point at which we started, we have here a hypothesis of great importance, because it has the signal merit of stimulating accurate and minute observation in a field of inquiry in which hitherto a spirit of speculation has been chiefly dominant.

ROYAL DENTAL HOSPITAL OF LONDON.—The medical staff and lecturers of this hospital are giving a conversazione on Wednesday, Oct. 18th, at 8 P.M., at the Royal Institute Galleries, Princes Hall, Piccadilly. The occasion is the distribution of prizes by Mr. A. H. Gilkes, head master of Dulwich College.

Annotations.

"Ne quid nimis."

THE NATURAL HISTORY OF EPIDEMIC DIARRHŒA.

IN an interesting paper entitled "Season and Disease" Dr. Owen H. Peters[1] has studied the influence of seasonal variations of temperature and other meteorological conditions upon the epidemic rise and fall of epidemic diarrhœa and enteric fever. He showed that the time of the epidemic rise varies in different years, and that the time of attainment of summer temperatures also varies. A comparison of the two curves showed a very general correspondence between the early or late onset of the epidemic rise and the time of development of summer temperatures, but further observations demonstrated that it is not the mere arrival at a certain fixed temperature which is related to the date of the seasonal rise. From a study of these curves for a number of towns for certain periods of years it was suggested that the seasonal rise might be related to the cumulative effect of certain degrees of temperature extending over a certain time. As an example, it was found for London, Nottingham, and other large cities of the United Kingdom that after the arrival and continuance, without intermission, of the mean air temperature at 60° F. for a period of four or five weeks the main seasonal rise of diarrhœa mortality took place, the last fortnight or ten days of the period corresponding to the average duration of fatal attacks. On analysis of a considerable number of charts it was found that upon a rise to a favourable mean air temperature of 60° F. or a little below there is, firstly, an interval of two weeks during which no increase of diarrhœa cases occurs, or of four weeks before deaths, afterwards there is a slight rise, but an additional period of one to two weeks or a little more may elapse before the main rise develops. It was also evident that the influence of temperature upon the seasonal epidemicity of diarrhœa is a very important one, since failure of the summer temperatures to reach a certain height prevents it altogether, and, further, the epidemic mortality invariably comes to a standstill a fortnight after the weekly air temperatures have passed in a decided way below 50°. Dr. Peters has further studied this question in an interesting and careful examination[2] of the features of an outbreak of epidemic diarrhœa in certain districts of the town of Mansfield during the summer and autumn of 1908. Two areas of the town were systematically investigated by Dr. Peters himself, and the features of 390 separate attacks of the disease were investigated. On the basis of his observations he gives an exhaustive account of the conditions relating to the disease, and examines the various theories as to its causation and spread. He found that the incubation period was from six to 30 hours in length, but that it might possibly be longer. School attendance seemed to have little effect on the spread of infection, but the sharing of yards in common apparently had a marked influence upon the spread of infection. Dirtiness of the home increased the incidence of the disease, probably through carelessness in dealing with the motions, especially those of the young children. There was a comparatively low incidence during the first year of life, which was probably due to breast-feeding. It is important to notice that the attack age incidence was quite different from the mortality age incidence, which is far greater under

[1] Season and Disease: a Preliminary Study. By Owen H. Peters, M.D. Melb. Reprinted from the Proceedings of the Royal Society of Medicine.

[2] Observations upon the Natural History of Epidemic Diarrhœa, from the Journal of Hygiene, vol. x., No. 4, December, 1910.

the age of two years. Boiling the cow's milk given as food gave no protection, and it was found that the milk-supply played no part, unless of a general kind, in introducing diarrhœa into the home. The part played by personal infection, direct or indirect, by flies and the possible rôle of ground infection are carefully examined. Dr. Peters found that infection within the home was probably the commonest method of contracting the disease. The evidence was in favour of personal infection and fly carriage, and rather against ground infection. Comparing the diarrhœa curve with the curves of temperature and fly prevalence, it showed a delayed rise, variations with their variations, and a definite falling away from their declining curves. Careful analysis of these curves proved to be quite compatible with the theory of fly infection, but certain crucial tests which Dr. Peters outlines as necessary to establish this theory have still to be proved. This monograph is a thoughtful and valuable contribution to the literature of a devastating disease, and deserves careful consideration by all who are concerned in its study.

VACCINATION IN BURMA.

THE triennial report on vaccination in Burma, by Major H. S. Harriss, I.M.S., Superintendent-General of Vaccination, has recently been issued. The total number of vaccinations performed during the period under review was 1,167,673, a decrease of 102,280 on the preceding triennium. The percentage of successful primary vaccinations was 94·80, as compared with 91·05 in the previous triennium; that of successful revaccinations was 62·71, as against the previous 54·74. The average number of operations performed by each vaccinator was 1472, as compared with 1721 in the previous period, a decrease of 249. In Lower Burma the percentage of children successfully vaccinated was 25·56, as compared with 26·27 for the previous triennium. No comparison for Upper Burma can be instituted, as registration of births was introduced there only in 1907; but there is a steady decrease in the percentage of protected infants in Lower Burma, and in Upper Burma so far as figures are forthcoming. As regards the general protection of the population, during the present triennial period the protection per 1000 was 30·49, as compared with 33·16 in the previous triennium. There are three vaccine depôts in Burma—namely, Meiktila, Rangoon, and Loimwe, the last-named having been opened during the past year. Special mention is made of the excellent work of Captain H. A. Dougan, I.M.S., in charge of the Meiktila depôt. The introduction of lanoline lymph for use in remote districts has been attended with marked success at Akyab, where it gave 94·2 success as against 84·4 with glycerine lymph. Tavoy and Mergui also recorded 94·2 per cent. success with lanoline lymph. Liebrich's lanoline in tins gives uniformly good results, provided the lanoline in the centre of the tin alone is used. The vaccination expenditure has risen to Rs.5,23,910, as compared with Rs.3,80,597 in the previous triennium, an increase of Rs.1,43,313. In view of the decrease in the total number of vaccinations performed these figures are recognised as unsatisfactory. This great increase of expenditure is ascribed to (*a*) increase in the number of native superintendents of vaccination and vaccinators; (*b*) the employment of a large number of peons in areas in which postal arrangements are defective; and (*c*) the increased pay of vaccinators for length of service. The three classes of officials concerned in vaccination are the vaccinators, the native superintendents, and the civil surgeons. The vaccinators are said to be mostly young inexperienced men in whom the Burmese have no trust; further, they are not reliable, for 17 have had to be dismissed during the season of 1910–11 for falsification, fraud, or acceptance of gratuities. The Lieutenant-Governor, in his resolution on the report, combats the idea that the percentage of men who had to be removed is high, and believes that the fault is largely due to lack of trustworthy and efficient supervision. He considers it doubtful whether the native superintendents, on a pay varying from Rs.25 to Rs.60 a month, can be trusted to exercise adequate supervision. On the other hand, civil surgeons with a large hospital at headquarters and several smaller hospitals at different stations, who are vice-presidents of municipalities, superintendents of jails, and sanitary officers for the whole district, to say nothing of doing a certain amount of private practice among European residents, cannot possibly find time to inspect thoroughly the work of the vaccinators. Major Harris, the Sanitary Commissioner, recommends the appointment to headquarters hospitals of assistant surgeons, which would allow the superintendent of vaccination to proceed on the prolonged tours necessary for the accomplishment of satisfactary inspection. He further recommends an increase in the number of Deputy Sanitary Commissioners to be constantly on tours of inspection. With regard to the native superintendents, he considers that it would be a better practice to promote old and trusty vaccinators to such posts, both as being more reliable than the young and inexperienced native superintendents at present appointed on passing an examination, and as offering hope of promotion to the vaccinators. He remarks on the general distrust, and in some cases even hostile attitude, to vaccination among the natives of Burma, who in large part prefer the practice of inoculation. (It is worthy of notice, in view of the letters in our columns on August 26th and Sept. 9th, and the further letter of "E. A. A." in the current issue, that no reference is made in the report to tattooing as a substitute for vaccination, although the practice of inoculation is condemned.) This practice was rendered illegal by the Prohibition of Inoculation Act, 1908, which, however, is in force in only two districts; and the Sanitary Commissioner considers its extension to be urgently required, seeing that out of 20 districts reporting small-pox epidemics 11 reported inoculation, and in 6 epidemics were said to be the direct result thereof. The Burma Vaccination Act of 1909 gives power to health officers to enforce vaccination in certain circumstances in Rangoon and in other places where it may be urgently required, and also provides for the vaccination of coolies. To ensure the vaccination of all newly born children a special combined birth and vaccination register has been introduced.

STRANGULATED HERNIA WITHOUT VOMITING.

VOMITING, at first of stomach contents and later of fæcal material, is usually regarded as an essential symptom of strangulated hernia. In his "Clinical Lectures" Sir James Paget says: "If I were asked which of the signs of strangulation I would most rely on as commanding operation I would certainly say the vomiting." However, in his "System of Surgery" Sir Frederick Treves is not quite so dogmatic, for he says: "Vomiting appears early, is a marked and *almost* constant symptom." In the *Journal of the American Medical Association* of June 24th Dr. James R. Judd has reported a case of strangulated hernia which was remarkable in the fact that vomiting was entirely absent. The patient, a Chinaman, aged 64 years, was admitted into hospital. He had been troubled for 15 years with an inguinal hernia which had gradually enlarged. On several occasions he had difficulty in reducing it, but always succeeded in the end. He never wore a truss. Four days before admission the tumour increased in size and he could not reduce it. He had suffered considerable pain and the bowels had acted once. According to his statement, which was corroborated

by all his friends and relatives, he did not vomit at all. On examination he was a well-nourished man with a pulse of 120, a temperature of 101°F., and embarrassed respiration. The abdomen was distended and tympanitic. In the right inguinal region was a tense, tender swelling which involved the right side of the scrotum. The overlying skin was reddened and œdematous, and there was no impulse on coughing. The usual incision revealed a tense sac adherent to the scrotum and containing a loop of gangrenous intestine. The sac was filled with fluid fæces and gas, and fæces were seen escaping from two openings in the bowel. The sac was irrigated, the constriction relieved, and the gangrenous bowel wrapped in moist gauze. The loop was then brought well outside the abdomen and the distended bowel divided at a safe distance from the gangrenous area. Much fluid fæces and gas escaped. Twelve centimetres of intestine, with a wedge-shaped piece of mesentery, were removed, and end-to-end anastomosis was performed. The spermatic cord was found to be flattened, and its vessel did not pulsate. The right testis was greenish-black and did not bleed on incision. The cord was therefore ligatured and removed with the testis. The sac, which was much thickened and adherent, was removed and the neck sutured at the internal ring. The inguinal canal was closed in the usual manner, and drainage was provided at the lowest end of the wound. Except for slight discharge from the drainage tract the wound healed by primary union, and recovery was uneventful. The gangrenous condition of the testicle is a very unusual condition in strangulated hernia, and was evidently due to pressure of the sac on the cord.

AN OUTBREAK OF CHANCRES OF THE LIP FROM KISSING.

THE transmission of syphilis to the "innocent" by kissing is too well known, but transmission to a number of persons at the same time has seldom been recorded. In the *Journal of the American Medical Association* of Sept. 2nd Dr. J. F. Schamberg of Philadelphia has reported the following distressing occurrence, which should serve as a warning against kissing games. A coterie of young men and women of ages varying from 16 to 22 years gave a benefit minstrel performance, which was followed by a banquet at which juvenile kissing games were played. One of the participants, a man, aged 22, had a sore on the lip. Six young women kissed by him developed chancres of the lip. A young man also developed a chancre apparently from kissing one of the young women on whom the virus had been deposited. In addition, a young woman kissed by the offender at another social function developed chancre of the lip. The matter was brought before the Department of Health of Philadelphia by a physician under whose care three of the patients came, and Dr. Schamberg was requested to investigate it. The offender was identified and said that he noticed a sore on the left side of the lower lip on Feb. 12th, 1911, and on March 3rd consulted a physician, who did not inform him of its nature. However, on being interrogated, the physician declared that he advised the young man to take all precautions. On March 4th the kissing games took place. On examination on June 20th he presented the remains of a chancre of the lower lip, tonsillar ulceration with mucous patches, and a maculo-papular eruption. There was no law in the State giving the health authorities a right to deprive a syphilitic subject of his liberty, but there was a law, nearly a century old, empowering them to quarantine a person known to be spreading contagious disease. With his consent the patient was taken to the municipal hospital and given an injection of salvarsan. If he had refused he would have been quarantined. Five or six other young women were kissed by him at the first function without contracting syphilis. Of those who developed chancres four had no knowledge of any abrasion on the lips previously, one had a fissured lip, and one was in the habit of biting her lips. Four of the chancres were on the lower lip, two on the upper, and in one case both lips were involved. The source of the chancre in the young man could not be determined, but as he was given to frequent promiscuous kissing it was presumed the disease was contracted in this way. This unfortunate occurrence, as Dr. Schamberg observes, teaches several lessons. It shows the importance of teaching the public the dangers of promiscuous kissing and the great responsibility placed on medical men of safeguarding the public from their luetic patients by giving due warning. We would add that it forms an argument for bringing venereal diseases under sanitary control.

SANITATION AND PLAGUE.

THE view which has been generally held as to the relation of insanitary conditions to the prevalence of plague has generally been that they had no direct effect upon the diffusion of the disease, except in so far as they might favour the infestation of premises by rats. To this opinion there are, of course, dissentients, who maintain that the first step towards the prevention of the spread of plague is the improvement of the general sanitary circumstances of the house, the village, the town, or the district. In THE LANCET of Sept. 16th we drew attention to the anomalies of plague incidence in India, and particularly to the remarkable freedom from plague epidemics experienced by the province of Eastern Bengal and Assam, the precise causes for which were apparently not known. Since commenting on this subject we have had the opportunity of reading the recently issued annual report for 1910 of Lieutenant-Colonel E. C. Hare, I.M.S., Sanitary Commissioner for that province. In his report reference is made to the well-known immunity of Eastern Bengal from plague, and in this connexion the Sanitary Commissioner refers to an inquiry conducted during 1910 by Captain J. C. G. Kunhardt, I.M.S., on behalf of the Commission for the Investigation of Plague in India, who had visited the province. The full report of this officer has not yet been published, but it is stated he had come to the conclusion, as a result of observations made in Dacca, Chittagong, and other places, that the towns in Eastern Bengal were infested by the rat (Mus rattus) to a much less extent than the towns in other parts of India, and that the reason for this appeared to be due in part to the construction of the dwellings, some, on the one hand, being built more solidly with cement plinths and roofs made of stone slabs, while, on the other hand, some were constructed of more flimsy materials, with walls of bamboo matting and roofs of corrugated iron or light thatch, in any case affording little shelter for rats. The houses, too, were found by Captain Kunhardt to be better lighted, and they were kept in better repair. The people themselves also were more cleanly in their habits, and they did not allow so much rubbish or refuse to collect around their homes. In a word, there seems to be a higher standard of sanitation in Eastern Bengal than in some other parts of India. Whether this is only a part of the explanation of the province's immunity from plague it is not possible to say until the Commission's full report has been received. But this evidence corroborates what has long ago been suggested by some sanitarians in India. In this connexion we may be allowed to quote a passage from the annual report for the year 1908 written by Major C. E. Williams, I.M.S., Sanitary Commissioner for Burma. In protesting against the ignoring of the improvement of general sanitary conditions as conducing to the prevention of plague, and also protesting against all the efforts being concentrated solely upon the

destruction of rats and fleas, Major Williams went on to say that many district medical officers had, in consequence of the advice they had received from the Plague Commission, "neglected the improvement of the general sanitary conditions to follow the *ignis fatuus* of a pulicide propaganda, in an attempt to break the chain of infection at its apparently feeblest link. The practical sanitarian, however, cannot fail to recognise that for him the real source of predisposition of plague epidemics so conspicuous among Asiatic races lies in the insanitary conditions among which the poorer classes live, which foster the prevalence of rats and insect vermin, and that a true prophylaxis is to be found in the amelioration of these conditions."

TUBERCULOUS PLEURISY DUE TO EMBOLISM.

UNDER the somewhat vague title "Zur Kenntnis der Lungentuberkulose" Professor Aufrecht has reported in *Berliner Klinische Wochenschrift*, No. 30, 1911, an interesting case which throws light on the etiology of tuberculous pleurisy. The patient, a man aged 60, consulted him for an enlargement of the cervical glands, which had grown from the size of a hazel nut to that of a child's fist in the course of six months. Excision was advised, but refused. The patient went elsewhere and his glands were massaged. Shortly afterwards he was seized with violent pain in the right side of the chest, and dulness was detected over the middle lobe of the right lung. He now consented to extirpation of his glands, which were found to be almost completely caseous and to contain numerous tubercle bacilli. The dulness over the lung continued, and a serous exudate was detected in the right pleural cavity. After eight months' illness the patient died. At the necropsy 200 c.c. of cloudy fluid were found in the right pleural cavity. The middle lobe of the right lung was larger than usual, and it was completely converted into a yellowish-grey, cheesy mass. The massage had evidently displaced from the cervical glands a thrombus which had been carried to a branch of the pulmonary artery, supplying the middle lobe of the right lung. The simultaneous occurrence of pleurisy and pulmonary tuberculosis may thus be traced to an embolus containing tubercle bacilli and causing an infarct of the lung. Such an embolus is probably more often derived from mediastinal than from cervical glands, as the former are oftener tuberculous than the latter. Professor Aufrecht concludes that this origin of tuberculous pleurisy is not infrequent, especially in such cases which, shortly after the onset of pleurisy, present physical signs of pulmonary disease. He therefore advises a guarded prognosis in early pleurisy which may be the outward and visible sign of deep-seated and acute pulmonary tuberculosis.

POETRY AND SCABIES.

SCABIES is hardly a complaint which one would expect to be associated closely with the Muses, but such apparently is not always the case. Dr. Haldin Davis sends us the following interesting note on the subject: "In the year 1788 a young maiden lady, by name Weissel, the daughter of the Procurator of the University of Marburg, fell ill with an affection of the skin which her medical attendant, who was, as she alleges, one of the most skilful of physicians, diagnosed as 'scabies humida.' Whether this affection is identical with the scabies of modern times is more than doubtful, for in those days the term scabies was applied to a number of different conditions, including eczema and syphilis (scabies hispanica). Notwithstanding the attentions of her physician this lady's illness lasted no less than six months, during which time she was reduced to the lowest ebb of misery and distress. She records that during the entire period she was almost wholly without sleep. Finally, she sought relief in poetry, and six of her effusions were collected by an unknown admirer, and published in the 113th number of the *Political and Philosophical Magazine* (*Staats und Gelehrten-Zeitung*) of the Principality of Hesse-Cassel. Thence one has been rescued from obscurity and republished in the *Deutsche Medizinische Wochenschrift* for August 24th. It is entitled, 'Trost eines guten Gewissens auf dem Krankenbette,' which is, being interpreted, 'The Consolation of a Good Conscience on the Sick-bed.' It is not without poetical merit. After six months' suffering she sank into a sort of trance, and on awaking from this implored the doctor to adopt another line of treatment, however dangerous it might be. He acceded to her wishes, and his efforts were so speedily crowned with success that within a month she had fully recovered. Dr. Schelenz, who has made this contribution to the history of medicine and rescued a poetess from oblivion, is of opinion that she suffered from an eczema of purely nervous origin. The subsequent history of the poetess presents few points of interest. She married in 1792, had nine children, and the only other poems which she published were dedicated to her son in 1814, at that time a 17-year-old officer fighting in the Napoleonic wars."

DILATATION OF THE COLON AS A TEST FOR CHRONIC APPENDICITIS.

THAT chronic appendicitis may manifest itself as persistent dyspepsia of various forms, and therefore escape diagnosis, has been fully recognised. In the *American Journal of the Medical Sciences* for July Dr. W. A. Bastedo has called attention to a test which he has found of great value in the diagnosis of chronic appendicitis, and which has served him when all other methods failed. A colon tube is passed for a distance of 11 or 12 inches and air is injected through it by means of an indiarubber bulb. If as the colon distends pain and tenderness become apparent at McBurney's point there is appendicitis. Of course, this test should not be used in an acute case. Dr. Bastedo thinks that it may prove useful in any persistent abdominal trouble or digestive disturbance for which no cause can be found. In cases of suspected appendicitis in which the diagnosis was doubtful and he hesitated to advise operation because tenderness at McBurney's point was elicited only by very deep pressure, or because there was similar tenderness at other points in the abdomen, dilatation frequently caused disappearance of tenderness at all places except at McBurney's point, where it was intensified. Finally, dilatation enabled the differential diagnosis to be made between appendicitis and right side pelvic trouble in young women in whom vaginal examination was impossible except under ether. The following are some examples. A painter had attacks of abdominal pain, without nausea or vomiting, for 18 months. They became more numerous and in the last he had to lie down for one afternoon. He was told that he had painter's colic. The pain was generally just above the umbilicus or high up beneath the ribs. There was no line on the gums. On dilatation of the colon a small umbilical hernia appeared and pain was felt at two spots —McBurney's point and just below the umbilicus. Operation for the hernia and appendicitis was advised, but, as the diagnosis was not confirmed by others, was declined, and the patient was treated for three months for plumbism and indigestion. The attacks increased and became more localised in the appendix region. The dilatation test was again performed and proved positive. On operation a chronically inflamed appendix covered by veil-like adhesions, which extended to the hernial opening, was found. The appendix was removed and the hernia opening closed, and the attacks ceased. In a second case a physician had in two years five attacks of severe abdominal pain with prostration and vomiting. The pain was diffuse, never

localised, and lasted about a day; the temperature never rose above 99° F., and the pulse was normal or slow. A positive diagnosis was not made, but appendicitis was suggested. Two days after the last attack, which was so severe as to require the administration of morphia, Dr. Bastedo saw him. Slight tenderness could be elicited on very deep pressure at McBurney's point, but on dilating the colon acute pain appeared in the appendix region as well as tenderness at the point. Operation revealed a chronically inflamed appendix with a constriction close to the cæcum. There has been no attack since the operation—an interval of almost a year. In a third case, a woman, aged 24 years, suffering from mitral stenosis, had several attacks of cramp-like pain in the right iliac region. Twice or thrice this pain came on at the menstrual periods, but it also occurred at other times. Vaginal examination was not feasible, so the colon was dilated. At once dull pain was felt over the whole right lower segment of the abdomen, extending from McBurney's point to Poupart's ligament and to the middle line. Tenderness was slight and was most marked about half-way between McBurney's point and the symphysis pubis. Operation revealed a right ovarian cyst and normal appendix. Dr. Bastedo has used this test for four years and has had no case in which it was positive and the operation negative. But in two cases the test was negative and a typical attack of appendicitis followed six months later, and the test was presumably at fault. In several cases in the early days surgeons operated when the test was negative and in all a normal appendix was found.

TREATMENT OF TUBERCULOUS PERITONITIS BY INCISION.

TUBERCULOUS peritonitis is by no means a rare disease, for it is found in about 5 per cent. of all cases dying from tuberculosis, but it is rarer for it to form the sole or even the most conspicuous manifestation of the action of the tubercle bacillus. That it is possible for cases to recover from the disease without operation is certain, and Dr. H. P. Hawkins found from the examination of 100 consecutive cases at St. Thomas's Hospital that, though the mortality is less in cases treated by operation than in those treated without operation, the difference is slight. Judging by the results of published cases which had been submitted to operation, improvement or cure occurs in three-quarters of the whole number; but there can be no doubt that these figures are untrustworthy, for even in cases apparently completely cured relapses may occur, and, further, a successful case is far more likely to be reported than one which has ended fatally. The first instance of the employment of laparotomy in tuberculous peritonitis resulting in recovery occurred in the practice of Sir Spencer Wells; the abdomen was opened under the impression that an ovarian cyst was present, but tuberculous peritonitis was found, and the abdomen was closed. To the surprise of all who saw the case, the patient recovered, and she was alive and well at least 25 years later. Since this first success laparotomy has been performed many times for tuberculous peritonitis, and the best results have certainly been obtained in cases in which much exudation is present, and when there are few adhesions. Perhaps it will not be far from the truth to say that 50 per cent. of cases where such conditions prevail will recover after laparotomy. The results are not nearly so good if there be little or no exudation and many adhesions are present; yet recovery in such cases may occur, as in a case reported by a correspondent in the present number of THE LANCET (p. 918), that of a boy, 14 years old, suffering from tuberculous peritonitis, who was almost moribund, but who recovered rapidly after a small abdominal incision had been made. There is no little risk in cases with many adhesions that any attempt to break down any of them may give rise to a fæcal fistula, for the bowel wall is often greatly thinned, or general suppuration may be set up. The explanation of the improvement which follows laparotomy in tuberculous peritonitis is very difficult. Lauenstein suggested light as the curative agent, but the exposure is so short that this explanation cannot be accepted. When free fluid is evacuated by the operation it may well be that a medium favourable for the growth of the bacillus has been removed, but this explanation will not serve for those cases in which no exudation is present. Instances have occurred in which the abdomen has been opened for tuberculous peritonitis, and many tubercles have been seen, yet when a laparotomy has been performed a year later for some other cause, such as for cure of a ventral hernia resulting from the first operation, not a single tubercle has been visible on the peritoneum; therefore the tubercles really disappear. The only suggestions as to the cause that can be put forward with our present knowledge are either that somehow the balance of forces within the abdomen has been disturbed so as to make it unsuitable for the tubercle bacillus, which is somewhat difficult to grow, or perhaps the disturbance produced leads to the production of an auto-vaccine which immunises the patient. Be the explanation what it may, there can be no doubt as to the fact that in a large proportion of the cases recovery does ensue after a laparotomy has been performed, but the least satisfactory cases are those without exudation and with many adhesions, as in the case reported by our correspondent, who is to be congratulated on the success of his treatment.

HEMIHYPERIDROSIS AND PARADOXICAL SECRETION OF SWEAT.

IN the *Wiener Medizinische Wochenschrift* of April 22nd Dr. Wilhelm Presslich describes a case of disturbance of sweat secretion which presents certain unusual features. The patient was a member of the medical profession who came of a very neuropathic stock (his mother being a typical psychasthenic) and who had suffered at intervals from attacks of acute depression, associated with facial neuralgia. When he was a medical student his attention was called to the fact that during exertion he perspired only on the right side of the face, the left remaining quite dry. In the course of the next few years he observed that this area of unilateral sweating had gradually spread so as to include the right side of the neck, the shoulder, and both anterior and posterior aspects of the trunk to the level of the nipple. The condition remained unaltered during the next ten years. When the patient came under the notice of Dr. Presslich it was seen that even during rest and at a normal room temperature the right side of the face and upper part of the trunk were moist, while the remaining part of the body and the left side of the face were quite dry. With muscular exertion the affected areas "ran" with perspiration, but the patient did not feel hot, nor on palpation was the skin temperature raised. Only a moderate amount of perspiration was noticeable on the normal areas during violent exertion. The most curious feature of the case, however, consisted in a paradoxical sweat secretion which took place under the following conditions. On cold, misty days, as soon as the patient went out of doors the left side of the face and body seemed to become "stiff," and immediately thereafter it was covered with innumerable fine sweat-drops which usually disappeared after about a quarter of an hour. Similarly, by inhaling ammonia vapour or by eating any pungent substance such as horse-radish or mustard—indeed, even by merely thinking of such substances—the patient was able to make this paradoxical left-sided sweat secretion reappear, while the otherwise constantly moist right side became at the same time dry. There is

reason to suppose that these remarkable defects of sweat function are associated with impairment of the action of the sympathetic system, presumably medullary in origin. Cases have been described where organic disease of the medulla has been accompanied by disturbances of sweat secretion over the face and elsewhere, and in the present instance analogous defects were noted in the apparent absence of organic disease. In lesions of the medulla we may expect to find impairment of function of the vaso-motor and the secretory systems, which may or may not be associated with symptoms referable to impairment of the cervical sympathetic system.

PUERPERAL INFECTION WITH BACILLUS INFLUENZÆ.

THE application of bacteriological study to clinical medicine has done much in the past 20 years to modify our ideas as to the limits of the pathogenicity of various bacteria. We have learnt to regard the pneumococcal infection as a bacteriæmia, even when its pathogenic effects are apparently limited to the lung; and more recently still attention has been drawn to the frequency with which the bacillus coli communis becomes the cause of a septicæmia. One of the latest and most important additions to this increasing list of micro-organisms capable of causing deep-seated disease after transmission through the blood stream is the bacillus influenzæ. Various observers have been able to demonstrate it as the cause of meningitis and also of malignant endocarditis, usually of the "chronic infective" type; and now an interesting observation made by Dr. William Thalhimer in the *Johns Hopkins Hospital Bulletin* for August suggests that the genital tract may, in women at all events, be a port of entry for this bacillus. The patient, a woman 31 years of age, was seized with abdominal pain three days after a normal second confinement; the temperature was raised and there were several rigors. The following day she was admitted to hospital; at this date the temperature was 105°, but no pelvic lesion was discoverable. For some days after this the temperature ran an irregular course, and a mass was to be felt in the right broad ligament; but in less than a month the patient had so far recovered that she was able to leave the hospital. A blood culture was negative, but two types of organism, a small bacillus and a streptococcus, grew on agar inoculated from the interior of the uterus. The bacillus, which was the predominant micro-organism, proved in subculture to be Pfeiffer's bacillus influenzæ. The main points in the history of the patient which were of any suggestive value were an account of an attack, which was probably influenza, at the age of 16, and the fact that a year previously her husband was known to have had gonococcal epididymitis. The sole record of a case at all similar to this one, was that of a woman with bilateral non-puerperal salpingitis, suppurative on one side and serous on the other. Kiskault, who reported this case, found the influenza bacillus in the inflammatory exudation in both tubes. This patient also gave a history of an influenzal attack eight or nine years previously. In Dr. Thalhimer's case the bacillus was identified as that of Pfeiffer by two bacteriologists independently of each other.

Sir Donald MacAlister, chairman of the Pharmacopœia Committee of the General Medical Council, informs us that the committee, having resolved to proceed to the production of a new issue of the British Pharmacopœia, has appointed two editors to supervise the preparation of the work under their direction. The joint editors are Dr. Nestor I. Tirard, Professor of Medicine, King's College, London, who has been for many years the secretary of the committee, and Mr. Henry G. Greenish, F.I.C., F.L.S., Professor of Pharmaceutics, Pharmaceutical Society of Great Britain, who has acted as secretary of the Committee of Reference in Pharmacy.

THE Secretary of State for the Colonies has appointed Sir Ronald Ross, K.C.B., F.R.S., Professor of Tropical Medicine in the University of Liverpool, to be a member of the Advisory Medical and Sanitary Committee for Tropical Africa in succession to the late Sir Rubert Boyce.

WE regret to announce the death, in his eighty-third year, of Dr. Frederick William Pavy, M.D., F.R.S., LL.D., which occurred on Sept. 19th last, at his residence, 35, Grosvenor-street, London. A further notice will appear in our columns of this most distinguished physician and chemist.

THE ROYAL COMMISSION ON HUMAN AND ANIMAL TUBERCULOSIS.[1]

APPENDIX: VOLUMES I. AND II.

THE Final Report of the Royal Commission on Human and Animal Tuberculosis was published, it will be remembered, about two months ago,[2] and the first two volumes of the second part of, or appendix to, the report have now appeared. The first of these volumes describes the investigation of viruses obtained from cases of human tuberculosis other than lupus; the second describes the investigation of viruses obtained from cases of lupus; and both are from the pen of Dr. A. Stanley Griffith. A third volume, dealing with further work on old viruses, left incomplete when the second interim report was published,[3] with additional work on two of the recent viruses, and with the excretion of tubercle bacilli in the milk of animals experimentally inoculated, is announced. The investigations were undertaken at Blythwood, and have been proceeding since 1907.

In the following account of these two reports we have given Dr. Griffith's summaries substantially, for, while they are models of condensation, they indicate the extensive scope of the work for which he has been responsible and the precautions with which that work has been undertaken.

Volume I. Viruses from Cases other than Lupus.

Volume I., in recording the results of the investigation of the new cases of human tuberculosis other than lupus, includes a full account of the cultural and pathogenic properties of the tubercle bacilli isolated from them. First comes an account of the different viruses investigated, stating the type or types of bacilli isolated in each group of cases; second, a comparative study of the properties, cultural and pathogenic, of the two types of tubercle bacilli isolated; and third, the results of the experiments carried out to ascertain whether any of the properties of the tubercle bacilli isolated could be altered by residence in the bodies of mammals or birds.

The more detailed part of the report begins with a table of origins in which for each case, grouped according to the kind of tuberculosis, there are given a brief abstract of the clinical history and post-mortem notes of the patient and a statement as to the type of bacillus isolated. Fuller clinical and post-mortem notes are followed by summaries of the experimental results with the bacilli isolated, viruses here being arranged in numerical order. After these come the tabular summaries of the inoculation experiments performed on the different species of animals; the experiments with each species are tabulated separately and divided into groups according to the properties of the virus. Lastly, there are the full post-mortem notes of the larger animals grouped together according to the virus used, illustrated by graphic charts. A series of 67 photographs illustrating the types of growth of the cultures is appended. The pictorial charts exhibiting the lesions produced in calves, pigs, and

goats are to be included with other similar charts in a supplementary volume.

The original material consisted of tuberculous tissues, including fluids and pus, obtained after death, or by operation from 25 persons, and sputum from 30 persons presenting clinical signs of pulmonary tuberculosis. The list includes 10 cases of alimentary tuberculosis in children, 1 case of alimentary tuberculosis in an adult, 3 cases of tuberculous meningitis, 2 cases of general miliary tuberculosis (origin uncertain), 4 cases of pulmonary tuberculosis, 1 case of tuberculosis of the suprarenal bodies, 3 cases of tuberculosis of bones, 1 case of tuberculosis of a joint, and sputum from 30 cases of pulmonary tuberculosis.

It will be seen, therefore, that the subjects were of various ages, and that most of the chief varieties of tuberculosis were represented. The nature of the tuberculosis was in each case ascertained by cultures from the tuberculous lesions, and the original material was in every case inoculated into guinea-pigs for the purpose of obtaining cultures, and was occasionally tested for virulence on rabbits. As different types of tubercle bacilli are found in the same tuberculous lesion or in different lesions in the same subject, the properties of bacilli from lesions in different parts of the body must be ascertained before the disease can be rightly assigned to a particular type of bacillus. Detailed accounts are given of the methods employed to determine these properties and to estimate doses for inoculation.

The results of the investigation of the cases of primary alimentary tuberculosis in children are of particular importance. Of the 10 cases, varying in age from 7 months to 8 years and 7 months, in 7 the portals of entry of the bacilli were in the mucous membrane of the intestines, in 1 the point of entry was somewhere in the pharynx, and the other 2 were infected simultaneously from pharynx and intestine. Two of the children died of general tuberculosis, and in one of these there were tubercles on the meninges; three died of tuberculous meningitis, two of tuberculous peritonitis, and one of multiple stricture of the gut (tuberculous); the remaining two died from intercurrent disorders, and the tuberculous lesions were found at the post-mortem examination. Dr. Stanley Griffith is here careful to remark that in every case in which the disease was generalised cultures were made not only from the glands nearest the presumed sites of entry of the bacilli, but also from one or more of the remote lesions. The examination of a number of different strains from the same patient is specially important in the case of children because of their liability to infection with the bovine as well as with the human tubercle bacillus. In none of these cases, however, was there any evidence of a mixed or a double infection, the cultures derived from metastatic lesions being identical with those from the glands nearest the portal of entry of the bacilli.

The bacilli isolated from the ten cases were found to fall into two groups: (1) those which grew luxuriantly on artificial media and had a low virulence for the rabbit; and (2) those which grew less freely but had a high virulence for the rabbit and the calf. The second group were indistinguishable from the bacilli associated with bovine tuberculosis. Bacilli with the properties of the bovine tubercle bacillus were obtained from four children, all of whom died as a result of tuberculous infection. Dr. Griffith calls attention to the fact that these four cases furnish additional evidence to that brought forward in the second interim report that the bovine tubercle bacillus can when ingested produce severe tuberculosis in children and cause death either through extensive local changes or generalisation of the disease. In the series of 20 cases of mesenteric gland tuberculosis reported on in their interim report, 11 yielded cultures of the bovine tubercle bacillus. The other six cases of alimentary tuberculosis yielded cultures of the opposite type—i.e., bacilli which grew luxuriantly on glycerine media and showed low virulence for the rabbit. Two of the children, aged 7 months and 1¾ years, died of tuberculous meningitis; one, aged 7 years, of tuberculous peritonitis; and two, aged 9 and 10 months, of tuberculous meningitis and general tuberculosis; the remaining one, aged 4 years, died from pleurisy and pericarditis, the tuberculous lesions being found at the necropsy. The tuberculous lesions in these children presented no naked-eye features by which they could be distinguished from lesions produced in children by bovine tubercle bacilli. The number of bacilli in the lesions also afforded no certain indication of the kind of organism responsible for the disease. The only way, therefore, of ascertaining definitely which of the two kinds of bacilli is responsible for a tuberculous lesion is to isolate cultures and determine their cultural characters and virulence.

These ten cases bring the number of cases of alimentary tuberculosis in children under 12 years of age, in which the material was obtained after death, and which have been investigated by the Commission, up to 28; 14 of these cases have been shown to be due to the bovine tubercle bacillus, and 14 to the human tubercle bacillus. Interesting tables enable a comparison to be made between the two groups, when these important differences are revealed: (1) In the cases due to the human tubercle bacillus the generalised disease is more severe and widespread than in those due to the bovine tubercle bacillus; and (2) the bronchial glands are much more frequently and more severely affected by the human tubercle bacillus than by the bovine tubercle bacillus. A third and minor difference is the difference in average age at death. Taking only those which died of uncomplicated tuberculosis, it is found that the average age of the children which died of a human infection is 2·4 years, while that of the children which died of a bovine infection is 3·3 years.

One case of primary alimentary tuberculosis in an adult subject was investigated, a man, aged 70, who died from pneumonia. At the post-mortem examination caseous mesenteric and retro-peritoneal glands were found and there was no sign of tuberculosis elsewhere. Two strains of culture were obtained, one from the mesenteric glands through the guinea-pig, the other from a retro-peritoneal gland direct. On artificial media the two strains exhibited identical and luxuriant cultural characters, but they differed, however, in their virulence for the rabbit as the mesenteric gland strain produced in this animal, when inoculated subcutaneously, very slight retrogressive tuberculosis, while the retro-peritoneal gland strain produced in rabbits and calves inoculated subcutaneously general progressive tuberculosis.

We must refer our readers to the text of these volumes for accounts of the detailed work. Dr. Stanley Griffith summarises the lessons to be learnt from the first volume in the following clear terms:—

"In those cases of generalised tuberculosis caused by bacilli which had entered the body by way of the alimentary tract cultures were isolated not only from the glands nearest the points of entry of the bacilli but also from the disseminated lesions, and in several of the other cases in which there were lesions in different parts of the body more than one strain has been isolated and separately investigated. In two instances human and bovine tubercle bacilli were isolated from the same patient, and these were in each instance associated together in the same lesion, in one case a caseous retro-peritoneal gland in an old man aged 70 years who died of pneumonia and showed tuberculosis limited to the glands draining the small intestine, in the other a caseous bronchial gland in a child aged 4½ years who died of general tuberculosis. From other lesions in these two patients human tubercle bacilli only were isolated. The cultures isolated from the other cases fall readily into one or other of two groups, one containing bacilli indistinguishable from bovine tubercle bacilli, the other bacilli (human tubercle bacilli) which grow more luxuriantly and have lower virulence for the rabbit and much lower virulence for the calf than the bovine tubercle bacillus.

Bovine tubercle bacilli were isolated from four of the ten cases of alimentary tuberculosis in children, and from two of the cases of pulmonary tuberculosis (sputum). The four children in question died as a result of infection with bovine tubercle bacilli, the cause of death in one case being general tuberculosis, in another tuberculous meningitis, in another tuberculous peritonitis, and in the fourth stricture of the intestines following tuberculous ulceration; the ages of the children were 1, 2, 4, and 8½ years. The two patients from whose sputum bovine tubercle bacilli were obtained were adults aged 21 and 31 years. Pure cultures of bovine tubercle bacilli were isolated from one of these patients on four different occasions (twice direct) and from the other on two (once direct).

Human tubercle bacilli were isolated from the remaining 46 cases—i.e., six cases of alimentary tuberculosis, 31 of pulmonary tuberculosis, and nine of various other forms of

tuberculosis. Of the six children with alimentary tuberculosis, three were under 12 months old; the other three were aged 1¾, 4, and 7 years. Two died of general tuberculosis, 2 of tuberculous meningitis, 1 of tuberculous peritonitis, and 1 of pleurisy and pericarditis. The patients with pulmonary tuberculosis were aged 16 to 33 years, with the exception of one who was 50 years old.

In seven instances the material submitted, though apparently tuberculous, did not produce tuberculosis in guinea-pigs. In two of these cases emulsions of the material showed microscopically numerous bacilli indistinguishable from tubercle bacilli; in the others no tubercle bacilli were demonstrated. The material from one of the first two cases was the caseo-calcareous mesenteric glands of a girl aged 10½ years who died of heart disease; the tuberculosis was limited to the mesenteric glands. In the other case the material was caseous inguinal glands from a boy aged five years; tuberculous material from this boy had been investigated on two previous occasions, once when he was 14 months old, and again when he was 2½ years old. The earliest obtained material, caseous cervical glands, produced tuberculosis in guinea-pigs and a bacillus was isolated direct which was identical with a bovine tubercle bacillus. The second material, caseous cervical glands from the opposite side of the neck, and the third, the latest material, caseous inguinal glands, did not produce tuberculosis in guinea-pigs and culture tubes sown remained sterile. In the five cases in which no tubercle bacilli were demonstrated the material was calcareous mesenteric glands (or calcareous nodules from mesenteric glands) from adults (ages 20 to 90 years) who had died from various diseases; there were no lesions suggestive of tuberculosis anywhere else in the bodies of these patients."

The milk from four nursing women regarded as suffering from pulmonary tuberculosis did not produce tuberculosis in guinea-pigs; the diagnosis of pulmonary tuberculosis was confirmed in one case only by the demonstration of tubercle bacilli in the sputum by guinea-pig inoculation.

Volume II., Viruses from Cases of Lupus.

This volume deals with the results of the investigation of the tubercle bacilli found in the lesions of lupus vulgaris. Dr. Griffith states that this disease was dealt with separately from other kinds of human tuberculosis on account of the great variation in the properties of the tubercle bacilli isolated. The method of presenting the results follows the same lines in each series of investigations. The volume begins with a general account of the bacilli examined, with summaries in tabular form of the cultural and pathological properties (both original and after passage) of the various bacilli isolated. Then a table of origins is given, and next a full account of all that has been elucidated in connexion with each virus, including detailed case histories, descriptions of cultural characteristics, and summaries of the results of inoculations in various animals. The inoculation experiments are further presented in tabular form, according to the species investigated, and these tables are followed by a detailed account of the passage experiments with various cultures. Finally appear full post-mortem notes of the larger animals, arranged in groups according to the particular virus used, and illustrated by graphic charts. On pp. 479 and 480 are reproduced a number of photographs (20 in all) illustrating the types of growth of various lupus cultures on glycerin agar and glycerinated potato.

The investigations were carried out to determine whether the tubercle bacilli responsible for lupus vulgaris do as a rule vary in their properties from one or the other of the two types of tubercle bacilli which are the cause of other kinds of human tuberculosis. For this purpose material was used from 20 new cases of lupus, together with fresh material from an old case. From these viruses cultures were isolated and tested on artificial media and on various species of animals. The patients' ages ranged from 3¾ to 68 years; 6 of these were males and 15 females, and the duration of the disease varied from 3 months to 36 years. The method of investigation was exactly the same as in the case of viruses from other kinds of tuberculosis; in each instance a culture was obtained and its cultural characters and pathogenicity ascertained.

In order to obtain cultures the lupus nodules or pieces of affected skin were ground to a pulp and emulsified with salt solution. The filtered emulsion was inoculated into a series of two or three guinea-pigs intraperitoneally. In these emulsions acid-fast bacilli were very scanty. After three to five weeks one animal out of each series was killed, and if tuberculosis had developed culture tubes were sown from various lesions; and other tubes were sown from the other guinea-pigs when they died subsequently or were killed. The cultures from the tuberculous tissues were raised exclusively on egg medium. From this the bacilli were subcultivated for a few generations on serum, and then tested on various glycerin media. No cultural differences were observed between different strains of the same virus; but different viruses showed wide variations.

The lupus cultures, therefore, fall into two main divisions according to their cultural characters, as do those from other kinds of human tuberculosis. The first division contains bacilli which grow like bovine tubercle bacilli; the second contains cultures which grow luxuriantly like the human tubercle bacillus. All the cultures in the second division grew distinctly better than the most easy growing of those in the first division.

The Appendix considers the pathogenicity of the cultures under two headings: (*a*) original virulence; and (*b*) virulence after passage through the animal body. Animal experiments demonstrated that few of the cultures possessed the virulence of the group to which they culturally belonged. Of the nine which grew like bovine bacilli only one possessed the high virulence of the bovine tubercle bacillus, while of the 11 which grew luxuriantly only two were regarded by the investigators as possessing the virulence of the human tubercle bacillus.

Dr. Griffith's summary, from which we now quote at length, states that the cultures of tubercle bacilli isolated from the lupus material have shown considerable variation in their properties. Of the 20 viruses investigated, only three yielded cultures which are identical both in cultural characters and virulence with one or the other of the two established types of mammalian tubercle bacilli, the cultures from one of the viruses being typically "bovine," from two typically "human." Of the remaining 17 viruses, eight grew like bovine tubercle bacilli and nine like the human tubercle bacillus, but none exhibited the virulence characteristic of bacilli with such cultural characters.

The characteristics of the two standard types of bacilli in regard to virulence are briefly as follows: The bovine tubercle bacillus when inoculated subcutaneously produces in young calves (dose 50 milligrammes), in rabbits (dose 10 milligrammes), and in monkeys and guinea-pigs (very small doses) a rapidly fatal general tuberculosis. The human tubercle bacillus, on the other hand, when inoculated subcutaneously in large doses, is unable to produce in calves anything more than slight retrogressive general tuberculosis, and never gives rise in rabbits to tuberculosis severe enough to cause death within three months; for the monkey the human tubercle bacillus is as virulent, and for the guinea-pig nearly as virulent, as the bovine tubercle bacillus. The eight atypical lupus viruses with the cultural characters of the bovine tubercle bacillus proved to be less virulent than the bovine tubercle bacillus not only for the calf and rabbit, but also for the monkey and guinea-pig, and the extent to which they thus fell below the standard in virulence varied. Taking first the results of the inoculations into the calf and rabbit, six of the eight viruses displayed for these animals virulence which was less than that of a bovine tubercle bacillus, but greater than that of a human tubercle bacillus. A feature of interest in connexion with these six viruses was the irregularity of the results produced both in the calf and the rabbit by individual viruses. Of the two viruses that remain, one exhibited for the rabbit but not for the calf higher virulence than the human tubercle bacillus, while the other appeared to be less virulent than the human tubercle bacillus both for the calf and the rabbit.

For the monkey the variations in virulence of the eight atypical viruses roughly corresponded with those for the calf and rabbit, and Dr. Griffith specially notes that viruses which fell very little below the bovine tubercle bacillus in virulence for the calf and rabbit, and were therefore on a much higher level in the bovine and rabbit scale of virulence than the human tubercle bacillus, exhibited distinctly lower virulence for the monkey (and guinea-pig) than the human tubercle bacillus. The virus which from the results it produced in the calf and rabbit would have been classed among the human tubercle bacilli was for the monkey the least

virulent of the group, and caused much less severe effects in this animal than the human tubercle bacillus. For the guinea-pig the eight viruses were all less virulent than the bovine tubercle bacillus, and no clear gradation in virulence was brought out by this species of animal.

The other nine lupus viruses with the cultural characters of the human tubercle bacillus all displayed lower virulence than the human tubercle bacillus. The degree to which the virulence fell short of the standard was shown by experiment on the monkey and the guinea-pig to vary widely. As might be expected, no marked variations in the virulence of these viruses were brought out by the more resistant animals, the calf and the rabbit, in which ordinarily an average human tubercle bacillus produces when inoculated subcutaneously only slight disease; the possession of a very low grade of virulence was demonstrated, however, in several of the viruses by the production in the rabbit of no disease or only slight disease after intravenous inoculation, and in the calf of changes confined to the site of inoculation.

Thus the lupus viruses in each division, one containing 9 with the cultural characters of bovine tubercle bacilli, the other 11 with the cultural characters of the human tubercle bacillus, presented many grades of virulence ranging from standard to a very low level. These variations in virulence are represented graphically in a table. Three scales of virulence are drawn, the first for the calf, the second for the rabbit, and the third for the monkey. The properties, cultural characters, and virulence of the tubercle bacilli isolated from the lupus nodules do not appear to have any relation to the age of the patient or to the duration of the lupus in the individual.

In order to ascertain whether the lower than standard virulence of the atypical viruses was stable or unstable, observations were made on the virulence of several of the viruses after a single residence in, or after passage through, the bodies of animals.

In the first division six of the eight viruses were tested after residence in the animal body. In two instances the virulence was increased by residence both in the calf and in the rabbit, the recovered viruses being equal in virulence to a bovine virus. The relationship of these viruses to bovine viruses, which was indicated by their original properties, was by these experiments clearly established. The virulence of the other viruses, with one exception, was stable, no change resulting from repeated passage of them through the body of the calf. In the exception mentioned there was apparently a slight increase in the virulence of the virus during its residence in the fourth animal of one of two series of calves. Though passage failed to raise the virulence of these latter viruses to the level of fatal general progressive tuberculosis, Dr. Griffith has little doubt, judging from their cultural characteristics and the effects they produced in calves and rabbits, that they are bovine viruses which have become degraded in virulence. Another must also be regarded as a bovine virus. It grows like a bovine tubercle bacillus, and though it produced only a limited retrogressive tuberculosis in the calf it caused progressive tuberculosis in the rabbit. As regards another, if this virus was originally a bovine virus the only attribute indicating its pedigree is its mode of growth. On this assumption it would follow, as Dr. Griffith remarks, that cultural characteristics are a more stable quality in the human body than virulence.

In the second division four of the viruses were tested after a single residence in the animal body; the virulence of three was unaltered, while the virulence of the fourth was apparently increased by residence in the body of a monkey. No conclusion, however, can be drawn from the single experiment on the monkey. Apart from the decisive proof of identity with the human tubercle bacillus such as would be afforded by the increase to standard virulence as a result of animal passage, the original properties of the viruses in this division sufficiently indicate their close relationship with the human tubercle bacillus; they possess the cultural characters of the human tubercle bacillus; their virulence for the calf and rabbit is low, and they have induced typical tuberculosis in all the monkeys and in the majority of the guinea-pigs inoculated with them, the effects produced in these animals differing from those following the inoculation of human tubercle bacilli only in their lesser severity.

The facts established with regard to the cultural characters and pathogenicity (original and after passage) of these atypical lupus viruses suggest strongly to the investigators that they were dealing with attenuated varieties in one case of the bovine tubercle bacillus, in the other of the human tubercle bacillus. Was the attenuation of the lupus bacilli antecedent or subsequent to entry into the individual affected with lupus? If antecedent to entry then similar atypical forms should be occurring among the animals or the human beings which are the chief sources of human tuberculosis. But although 30 cases of bovine tuberculosis, 59 cases of swine tuberculosis, and 47 cases of pulmonary tuberculosis in human beings have been investigated by the Commission, no tubercle bacilli have been obtained from these sources which are identical with any of the atypical varieties obtained from lupus. From the horse, however, cultures have in two instances been isolated, which resemble atypical cultures in the first division of the lupus series. Both these viruses were proved to be attenuated bovine viruses by the fact that their virulence was, by passage through the calf, raised to the level of that of a bovine tubercle bacillus. It seems unlikely that any of the lupus patients derived their infection from the horse, since equine tuberculosis is not of frequent occurrence, while the flesh of horses is not commonly eaten by human beings.

There remains to be considered the possibility of attenuation subsequent to entry into the human body. No attenuated forms either of the human or the bovine tubercle bacillus have been isolated from human tuberculous lesions other than lupus, though 115 cases, including nearly every variety of tuberculosis, have been examined. If the attenuation of the lupus bacilli took place in the human body from which they were isolated, it would seem that the influences favouring the change are resident in the skin only, or in more marked degree in the skin than in other regions of the body.

To ascertain whether tubercle bacilli do become degraded in virulence by residence in the cutaneous tissues a re-investigation of the lupus from three of the patients was undertaken. Material was obtained from one patient six months, from another two years, and from the third three years and seven months after the material for the first investigation was removed. Of these, the first had yielded at that investigation typical bovine, the second slightly attenuated human, and the third attenuated bovine tubercle bacilli. In the first two cases no difference either in cultural characters or in virulence between the first and second group of cultures was detected; in the third the later obtained culture produced in the calf more severe results than the first, but was not apparently more virulent for the rabbit. The cultural characters of the later strain of each of the three cases were identical with those of the first. Residence in the skin of six months in one case, two years in another, and three years seven months in a third had not caused any diminution in the virulence of the bacilli or alteration in their cultural characters. It would be interesting, says Dr. Griffith, to obtain cultures from these cases once more, and also from as many as possible of the other cases, and compare their properties with those of the cultures originally isolated.

Though no direct proof that bacilli lose virulence when resident in the skin has been secured, the gradation in virulence of the variants from the standard type and the absence of similar varieties in the food animals and in other kinds of human tuberculosis strongly support the view that it was in the cutaneous tissues of the lupus patients that the degradation in virulence took place.

Dr. Griffith then considers the question whether the bacilli of these variant cultures can be regarded as in a transitional or intermediate stage of transformation from bovine into human tubercle bacilli. As the bovine tubercle bacillus differs from the human tubercle bacillus both in cultural characters and virulence, he anticipates that a gradual transition from the one type of tubercle bacillus to the other would be marked in its intermediate stage by forms which showed a change in cultural characters alone, in virulence alone, or in both properties simultaneously. And the question arises: Do any of the variant cultures stand in the intermediate position between the two types in either or both of these respects?

First, as regards cultural characters. None of the cultures can be regarded as intermediate in this respect since it has been possible to classify every lupus virus either as a bovine tubercle bacillus or a human tubercle bacillus on the basis of cultural characters alone; not one was in this sense equivocal. There is, however, the possibility that a bovine

tubercle bacillus might have fully acquired the characteristic cultural features of the human tubercle bacillus whilst retaining a virulence that would entitle it to be classified among the bovine tubercle bacilli. But there was not found among the viruses of Division II. any example of such a eugonic virulent virus.

Secondly, as regards virulence. Considering first the results in calves and rabbits, animals which have habitually been employed to differentiate between bovine and human tubercle bacilli, the table referred to already shows that there is a series of lupus viruses which in respect of virulence for these animals are intermediate between bovine and human tubercle bacilli; all these viruses had the cultural characters of bovine tubercle bacilli. Had the pathogenic powers of these viruses been lowered for calf and rabbit alone, and not for monkey and guinea-pig, the conclusion would have been inevitable that in these instances cultures were becoming transformed. But inoculation experiments on monkeys and guinea-pigs, animals equally susceptible to both types of tubercle bacilli, have shown that these viruses were reduced in virulence for these species also; in fact, the nearer their virulence for bovines and rabbits approached that of the human tubercle bacillus, the lower it proved for the monkey and guinea-pig. Thus the apparent bridging of one gap was accompanied by disclosure of another equally broad. It was to be anticipated that a bovine bacillus in process of transition into a human bacillus would, so long as it remained more virulent than that bacillus for the calf and rabbit, prove equally virulent with that bacillus for the monkey and guinea-pig; and the circumstance that the lupus viruses in question did not fulfil this condition, that on the contrary they would need to re-acquire full virulence for the monkey and guinea-pig for classification with the typical human virus, precludes Dr. Stanley Griffith from accepting them as transitional in type. In his view, and on the facts so far observed, these dysgonic variant viruses are to be regarded as no more than attenuated varieties of the bovine tubercle bacillus, just as the eugonic variants are to be regarded as attenuated human tubercle bacilli, and do not stand in any closer relation to the human tubercle bacillus than does the typical bovine tubercle bacillus.

THE COLONIAL MEDICAL SERVICE.

FULL particulars of the opportunities for medical practice under the Colonial Office, together with the rates of pay and conditions of service, were not included with the information concerning the public services which was given in the last Students' Number of THE LANCET. We are, however, constantly asked for details, in supplement to those published in the Students' Number, by intending applicants who have not seen our previous articles. The following summary will be useful.

Medical appointments in the public service of our Overseas Dominions are, in the case of the self-governing States, entirely under the control of the local governments. In what are called the Crown Colonies the appointments are filled by the Secretary of State. In Ceylon, Mauritius, Jamaica, Barbados, the Bahamas, and Bermuda vacancies are practically always filled locally by the appointment of qualified native candidates or by transfer from other colonies. Appointments in Malta are all filled locally, and those in Hong-Kong generally by transfer. In Bechuanaland, Basutoland, and Swaziland medical appointments are made by the High Commissioner, and nearly always from local candidates.

The Colonial Services, in which medical vacancies most regularly and frequently occur, and to which appointment is made by the Secretary of State, are the West African medical staff, the East African Protectorates, and the Straits Settlements and Federated Malay States.

Qualifications.—All applicants for colonial medical appointments must be between 23 and 35 years of age, and doubly qualified. Preference will be given to those who have held hospital appointments as house surgeons or house physicians. Testimonials as to character and professional competence will be required, and every candidate will be examined by one of the consulting physicians to the Colonial Office—Sir P. Manson (London), Dr. Hawtrey Benson (Dublin), or Lieutenant-Colonel J. Arnott, I.M.S. (Edinburgh).

Application for appointment is to be made to the Assistant Private Secretary, Colonial Office, Downing-street, London, S.W., by whom forms will be supplied, to be filled up by the candidate, who must name two referees as to character and capacity, and furnish testimonials. Candidates will be asked to attend at the Colonial Office to be interviewed by the Appointments Committee, which meets about once a month. The names of suitable candidates will be noted for consideration as vacancies arise, but no promise can be given that a candidate will eventually be offered an appointment.

The *West African Medical Staff* forms one service for Gambia, Sierra Leone, the Gold Coast, and Southern and Northern Nigeria. Preference is given to candidates over 25 years of age, also to those who are unmarried. There is a probationary period of one year. The salary commences at £400, rising by £20 annual increments to £500 a year. After five years medical officers who are recommended for a higher rate must take a study course; on obtaining satisfactory certificates and completing six years' service the salary is increased to £525, rising by £25 annually to £600 a year. An allowance of £12 is made on first appointment, for camp outfit. There are three principal medical officers, of whom two receive £1000 a year and one £800 to commence with, each appointment also carrying a duty allowance. There are also 26 senior appointments, with salaries ranging from £600 to £900, in addition to duty allowance. The ordinary term of service is one year, followed by two months' leave in England, for which period, as well as for the voyage home, full pay is allowed; half pay is given for the voyage out in the first instance. If the officer returns to the Coast he receives four (instead of two) months' leave at the end of the first year, and free passage is given. Private practice is allowed. Every candidate selected for appointment will be required to undergo a course of instruction in tropical medicine in London or Liverpool, for two or three months at the expense of the Government.

Service in East Africa, Uganda, Nyassaland, and Somaliland Protectorates.—Medical officers are appointed on probation for three years, after which, if their service is satisfactory, their appointment is made permanent. The salary is £400 per annum during probation, and on being confirmed as permanent it rises annually by £20 to £500. There are 39 appointments, as well as certain extra ones, carrying special pay. The principal medical officer in East Africa and Uganda receives £750 to £850, and in Nyassaland £600 to £700. Private practice is allowed. There are also seven temporary appointments (for three years) at £400 a year in connexion with sleeping sickness investigation in Uganda.

Straits Settlements and Federated Malay States.—In practice these medical services may be regarded as one, as officers are frequently transferred from the colony to the States, and *vice-versâ*. In the Settlements there are two house surgeons at Singapore and two at Penang, drawing £300 a year with quarters. There are about 20 posts with salaries varying from £300 to £900, some also having free quarters and some with permission to practise. The principal medical officer draws £1000 a year. In the Federated States medical officers also enter as house surgeons, with pay at £300, rising to £420, and furnished quarters; there are 13 second-grade medical officers, drawing £420 to £600, and eight first-grade officers, with £600 to £720, also with quarters. The senior medical officers at Perak and Selangor draw £900 to £1020, and £780 to £900 respectively, and the principal medical officer draws £1200. Private practice is not allowed, except in the case of the two senior and two of the first-grade officers. In this service all officers are required to contribute 4 per cent. of their salaries towards a widows and orphans fund.

In *British Guiana* there are 40 appointments, with salaries ranging from £300 to £900, and in most cases with right to practise. Candidates must have held a six months' resident appointment in some public institution. In *Trinidad* and *Tobago* there are 49 appointments of £250 to £400, with various allowances and the right to practise. In the *Windward* and *Leeward Islands* there are also 49 similar appointments.

Pensions are granted in the East African service at 50 years of age, on the scale of one-fortieth of the officer's retiring salary for every year of service. In most of the other colonies the pension age is 55, the rate allowed being fifteen-sixtieths of the average annual salary for three years previous to retirement, with one-sixteenth added for each additional year up to 35 years.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH FOR 1910.

City of Lincoln.—The public water-supply of Lincoln continues to be obtained mainly from the river Witham, two supplementary sources being available when the river is exceptionally turbid during times of flood. The sand filtration is maintained at a rate of percolation not exceeding 4 inches per hour. Since the great epidemic of enteric fever due to pollution of this public water-supply in the spring of 1905, the water has been sterilised by the addition of hypochlorite of sodium in the form of "chloros." This is added to the water before filtration at the rate of 1 part of "chloros" to 100,000 parts of water, equal to 8 parts of free chlorine per 1,000,000. Since the addition of "chloros" bacteriological examinations of samples of water taken weekly have invariably given negative results as to the presence of B. coli in 100 c.c. Following the passing of the Lincoln Corporation Water Act, 1908, the works in connexion with the new water-supply, which will be obtained at the outcrop of the new red sandstone at Elkesley, some 22 miles west of Lincoln, have been steadily progressing, and it is anticipated that this source will be available for use before the end of the present year. It is of interest, in view of the importance now generally attached to the carrier as an agent in the production of epidemic enteric fever, to extract from Dr. C. J. Coleman's report the number of notifications of, and deaths from, this disease since 1900.

Year.	Notifications.	Deaths.	Year.	Notifications.	Deaths.
1900	19	6	1906	22	3
1901	15	5	1907	17	3
1902	12	3	1908	22	5
1903	32	4	1909	32	4
1904	17	3	1910	21	1
1905	1054	131			

The epidemic of 1905 must have left behind it, according to modern conceptions, an altogether exceptional proportion of chronic carriers among the population of Lincoln, and, large as was the magnitude of the epidemic of 1905, it can hardly be supposed to have exhausted the susceptible material in a city with a population of over 50 000. The fact that the incidence of enteric fever since 1905 has been merely of the same order of magnitude as in the years preceding the great epidemic suggests that, in this instance at any rate, the chronic carrier has not shown any marked tendency to spread the disease.

Borough of Crewe.—Dr. G. G. Buckley's report shows that in this borough, with a population of some 45,000, diphtheria was prevalent to a notable degree during the later months of 1909 and the whole of 1910. During the latter year 290 cases were notified, the cases occurring in 228 families. Of these 32 died, giving a fatality rate of 11 per cent.; 173 occurred in school children attending a large number of different schools in Crewe. Special arrangements were made in the municipal laboratory for the bacteriological examination of swabs from notified cases, from members of the invaded households, and in the case of school children from other members of the school class. In all, 97 carriers were discovered among contacts who were examined in this way. None of these contacts were allowed to return to school until one, and in many cases two, negative swabs had been obtained, and as a preventive measure all were advised to receive an injection of antitoxin. Many acted on this advice, and Dr. Buckley states that "in no case where this was done did an attack of diphtheria follow." No schools were closed in consequence of the epidemic, although infants under 5 years were for a time excluded from five of the schools. In reporting on the Midwives Act Dr. Buckley refers to the high proportion of illiterate midwives still in practice in the town; the majority are unable to read a clinical thermometer, and 12 out of 35 are unable to write. The births registered in the borough during 1910 were 1112; 918 births were attended by midwives, and in regard to these only 13 records of sending for medical help were received. The figures as to vaccination show the marked fall in the numbers of infants vaccinated which has almost everywhere followed the Vaccination Act of 1907; the certificates of exemption, which before 1907 never exceeded 60 in the year, were as many as 275 in 1909, and 356 in 1910.

Urban District of Barnes.—Dr. F. G. Crookshank claims that the system of "bed isolation" in the wards of the Barnes Isolation Hospital, which he has described in the Transactions of the Royal Society of Medicine for 1910, has proved of the greatest service in overcoming difficulties due to an insufficiency of wards, and has been of great help in the prevention of secondary infections. The only disease, with the exception of variola, which he is not quite sure of controlling by this method is chicken-pox, where he thinks it advisable to supplement strict "bed isolation" by general inunction with eucalyptus oil—a practice which, on the other hand, he considers of doubtful utility as a means of preventing infection in the case of scarlet fever. In the rules for admission to the hospital it is stipulated that the medical superintendent may set apart any ward, not for the time being required for ordinary patients, as a private ward at a charge of 2 guineas per bed per week. A similar arrangement might usefully be made in many other isolation hospitals where there is a reasonable demand for greater privacy on the part of a considerable class of patients. In referring to the home treatment of diphtheria, Dr. Crookshank contrasts the public estimation of the medical man who recognises suspicious symptoms at the earliest moment and administers antitoxin, so that the child within a few hours is apparently well again, with that of the doctor who allows a similar case to drift so that ultimately a death-bed tracheotomy is called for. In the latter case Dr. Crookshank would have us believe that the relatives "are quite happy, and complacently assure each other that everything has been done," while in the former the doctor "bears the odium of being labeled an alarmist, and earns the undying hostility of the child's parents." It is to be feared that there is substantial basis for this complaint, though we doubt that the public is in the long run so easily deceived in its judgments. Dr. Crookshank has a protest to make against the present fashion of some medical officers of health to disdain the "common-sense sanitation" which was responsible for the great amelioration of the public health in the "sixties," "seventies," and "eighties," and their tendency to prefer preaching the necessity for socialistic experiments to the humdrum daily work of their districts. This criticism also is not without justification.

Port of Hull and Goole.—Dr. J. Wright Mason's report to the sanitary authority of this port shows the large amount of work which is done in Hull in connexion with disease on hips within the port, the sanitary conditions of vessels, and the prevention of exotic disease. The examination of imported foods is now undertaken systematically on a large scale, and forms a very important part of the work of the sanitary authority. Eleven cases of beri-beri in five ships came under notice during the year, and the character of the food of the patients is described. In one instance part of the diet of Chinese firemen attacked by this disease consisted of "native vermicelli," which the analyst reported to consist of the pith of a rush, with very little food value. The rice samples are usually described as inferior or dirty; in similar cases in future it would be useful to know the extent to which articles other than rice were included in the dietary, and whether the rice had been decorticated. No unusual mortality has been observed during the year among the rats at the various docks; specimen rats have been collected weekly and submitted to bacteriological examination, but in no case was any condition suspicious of plague detected.

Port of Cardiff.—Dr. E. Walford reports that under the cholera, plague, and yellow fever regulations a strict examination is made, during the day and night tides, of all vessels coming directly or indirectly from "infected" or "suspected" ports on their arrival at the Customs boarding stations. Twenty-three vessels from infected ports were medically inspected, principally from ports infected by cholera. During the year the rat catchers were engaged on 48 vessels, including five from plague-infected ports, and over 8000 rats were caught. During the past three years on an average 5000 black rats taken from ships coming from infected ports have been destroyed annually. Specimens examined from time to time at the Cardiff public health laboratory have proved negative as regards plague. Systematic inspection of shipping in respect of sanitary defects has been maintained, 8377 vessels having been inspected on arrival. Among the

matters to which special attention was given are included leaky decks; defective or unlined iron decks over bunks, causing damp beds; and defective ventilation, lighting, and drainage generally. The system of inspection of foods under the regulations of the Local Government Board is stated to be carried out satisfactorily. Large quantities of unsound food were destroyed during the year without having resort to legal proceedings.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 7423 births and 5290 deaths were registered during the week ending Sept. 16th. The revised estimate of population of these towns in the middle of this year is 16,157,797 persons. The annual rate of mortality in these towns, calculated on this revised estimate, which had been 21·2, 20·6, and 19·0 in the three preceding weeks, further declined to 17·1 per 1000 in the week under notice. During the first eleven weeks of the current quarter the annual death-rate in these towns averaged 16·6 per 1000, while in London during the same period the mean annual death-rate did not exceed 15·5 per 1000. The recorded annual death-rates in the 77 towns last week ranged from 5·1 in King's Norton, 6·8 in Handsworth (Staffs), 8·0 in Hornsey, and 9·7 in Reading, to 24·8 in Sunderland, 24·9 in Burton-on-Trent, 26·0 in Bootle, and 26·8 in South Shields. The 5290 deaths from all causes in the 77 towns last week showed a decline of no fewer than 599 upon the number in the previous week, and included 1701 which were referred to the principal epidemic diseases, against 2617 and 2087 in the two preceding weeks. Of these 1701 deaths from the principal epidemic diseases, 1540 resulted from infantile diarrhœa, 55 from whooping-cough, 41 from enteric fever, 27 from diphtheria, 25 from measles, and 13 from scarlet fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases last week was equal to 5·5 per 1000, against 8·4 and 6·7 in the two preceding weeks. The deaths of infants under 2 years of age attributed to diarrhœal diseases in the 77 towns, which had been 2714, 2461, and 1915 in the three preceding weeks, further declined to 1540 last week, and caused the highest annual death-rates of 8·9 in Bootle and in Preston, 9·0 in Hull, in West Hartlepool, and in Sunderland, 9·1 in Stoke-on-Trent, and 9·8 in Burnley. The deaths referred to whooping-cough, which had been 58 in each of the two preceding weeks, declined to 55 last week, and included 15 in London and 6 in Sunderland. The deaths attributed to enteric fever, which had risen from 11 to 28 in the four previous weeks, further rose last week to 41, and was, without exception, the highest number recorded in any week of the current year; 9 deaths were recorded in London and its suburban districts, 4 in Manchester, 4 in Hull, and 3 in Bradford. Of the 27 fatal cases of diphtheria, which were 10 fewer than the average in the four preceding weeks, 10 were registered in London and its suburban districts, and 2 each in Portsmouth, Birmingham, Liverpool, Salford, and Sunderland. The deaths referred to measles, which had declined from 59 to 29 in the four preceding weeks, further declined last week to 25, and was the lowest number recorded in any week of the current year; 4 deaths occurred in London, 3 in Nottingham, and 3 in Manchester. The 13 fatal cases of scarlet fever were 4 fewer than the number returned in the previous week, and included 2 in Bolton. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had been 1352, 1327, and 1349 at the end of the three preceding weeks, rose again to 1454 on Saturday last; 264 new cases of this disease were admitted to these hospitals during the week, against 132, 168, and 217 in the three previous weeks. These hospitals also contained at the end of last week 808 cases of diphtheria, 241 of whooping-cough, 119 of enteric fever, and 102 of measles, but not one of small-pox. The 1324 deaths from all causes in London last week showed a decrease of 186 upon the number returned in the previous week, and included 97 which were referred to diseases of the respiratory system, against 73 and 95 in the two previous weeks. The deaths attributed to different forms of violence in the 77 towns, which had been 147 and 171 in the two preceding weeks, were 169 last week, and 349 inquest cases were registered. The causes of 26, or 0·5 per cent., of the deaths registered in the 77 towns during the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified last week in Manchester, Leeds, Bristol, West Ham, Bradford, Hull, Nottingham, Portsmouth, and in 51 other smaller towns. The 26 uncertified causes of death last week included 4 in Birmingham, 3 in Liverpool, and 2 each in London, Blackburn and Sunderland.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of this year, 744 births and 516 deaths were registered during the week ending Sept. 16th. The annual rate of mortality in these towns, which had been 15·5, 17·2, and 16·4 in the three preceding weeks, declined again last week to 15·7 per 1000. During the first eleven weeks of the current quarter the annual death-rate in these Scotch towns averaged 15·1, and was 1·5 per 1000 below the mean rate during the same period in the 77 large English towns. The annual death-rates in the Scotch towns last week ranged from 9·1 and 9·9 in Leith and Paisley to 18 3 in Dundee and 21·8 in Perth. The 516 deaths in the eight towns last week were 20 fewer than the number in the previous week, and included 105 which were referred to the principal epidemic diseases, against 134 and 105 in the two preceding weeks; of these 105 deaths, 80 resulted from diarrhœa, 10 from diphtheria, 8 from whooping-cough, 4 from measles, 2 from scarlet fever, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 3·2 per 1000, the mean annual death-rate last week from the same diseases in the 77 large English towns having been 5·5. The deaths attributed to diarrhœal diseases, which had been 88, 113, and 78 in the three preceding weeks, rose to 80 last week, and included 67 of infants under two years of age; 39 deaths were recorded in Glasgow, 15 in Dundee, 9 in Edinburgh, 6 in Greenock, and 5 in Aberdeen. The deaths referred to diphtheria, which had been 5 and 8 in the two preceding weeks, further rose to 10 last week, and included 8 in Glasgow. The deaths attributed to whooping-cough, which had been 12, 10, and 12 in the three preceding weeks, declined last week to 8, of which 6 were registered in Glasgow. The 4 fatal cases of measles were equal to the average in the four preceding weeks, and included 2 in Glasgow. The 2 deaths from scarlet fever were equal to the number returned in the previous week, and were recorded in Glasgow and Aberdeen respectively. The fatal case of enteric fever occurred in Edinburgh. The deaths referred to diseases of the respiratory system in the eight towns, which had been 41, 24, and 53 in the three preceding weeks, declined last week to 41, and were 17 below the number in the corresponding week of last year. Of the 516 deaths from all causes in the eight towns last week, 142, or 28 per cent., were recorded in public institutions, and 25 deaths were attributed to different forms of violence. The causes of 12, or 2·3 per cent., of the deaths in the eight towns last week were not specified or not certified; in the 77 English towns the proportion of uncertified causes of death during the week did not exceed 0·5 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 592 births and 428 deaths were registered during the week ending Sept. 16th. The annual rate of mortality in these towns, which had increased from 19·3 to 22·1 in the three preceding weeks, declined to 19·4 per 1000 in the week under notice. During the first 11 weeks of the current quarter the annual death-rate in these Irish towns averaged 18·1 per 1000; in the 77 English towns during the same period the mean annual death-rate was equal to 16·6, whilst in the eight Scotch towns it did not exceed 15·1 per 1000. The annual death-rate last week was equal to 23·2 in Dublin (against 15·3 in London), 16·5 in Belfast, 19·7 in Cork, 11·5 in Londonderry, 20·4 in Limerick, and 20·9 in Waterford; whilst in the 16 smallest of these towns the mean annual death-rate did not exceed 18·4 per 1000. The 428 deaths from all causes

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING AUGUST, 1911.

(Specially compiled for THE LANCET.)

CITIES AND BOROUGHS.	Estimated population in the middle of 1911.	NOTIFIED CASES OF INFECTIOUS DISEASE.											DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.‡									Deaths from all causes.	Death-rate per 1000 living.†
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cerebro-spinal meningitis.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.*	Whooping-cough.	Enteric fever.	Diarrhœa and enteritis (under 2 years).	Total.	Annual rate per 1000 persons living.

* Including membranous croup. † The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard. ‡ Deaths from "typhus fever" and "other continued fevers" are not now distinguished in the Registrar-General's weekly returns; these two columns are therefore omitted from the Table.

in the 22 Irish towns were 59 fewer than the number returned in the previous week, and included 134 which were referred to the principal epidemic diseases, against 153 and 130 in the two preceding weeks; of these 134 deaths, 121 resulted from diarrhœal diseases, 5 from whooping-cough, 3 from scarlet fever, 3 from diphtheria, 1 from enteric fever, and 1 from measles, but not one from small-pox. These 134 deaths from the principal epidemic diseases were equal to an annual death-rate of 6·1 per 1000. The mean rate from the same diseases in the 77 English towns was equal to 5·5, while in the eight Scotch towns it did not exceed 3·2 per 1000. The deaths attributed to diarrhœal diseases, which had been 112, 141, and 117 in the three preceding weeks, rose last week to 121, and included 116 of infants under two years of age; 47 deaths occurred in Dublin, 35 in Belfast, 8 in Cork, 5 in Limerick, and 5 in Waterford. The 5 deaths referred to whooping-cough were equal to the average in the five preceding weeks, and included 3 in Dublin and 2 in Belfast. The 3 fatal cases of scarlet fever, which were slightly in excess of recent weekly numbers, were recorded in Dublin, Belfast, and Lurgan respectively. The fatal cases of diphtheria, enteric fever, and measles were all recorded in Dublin. The deaths referred to diseases of the respiratory system in the 22 towns, which had been 30, 31, and 44 in the three preceding weeks, were 42 last week. Of the 428 deaths from all causes in the Irish towns last week, 102, or 24 per cent., were recorded in public institutions, and 4 deaths were attributed to different forms of violence. The causes of 11, or 2·6 per cent., of the deaths registered in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes of death during the week under notice did not exceed 0·5 per cent. in the 77 large English towns, and was equal to 2·3 per cent. in the eight Scotch towns.

VITAL STATISTICS OF LONDON DURING AUGUST, 1911.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 4·4 per 1000 of the population, estimated from the unrevised returns of the recent Census to be 4,522,628 persons in the middle of the year. In the three preceding months the rates were 4·3, 4·4, and 5·1 per 1000 respectively. The lowest rates last month were recorded in Kensington, the City of Westminster, St. Marylebone, Battersea, and Lewisham; and the highest rates in Hackney, Finsbury, Stepney, Deptford, and Woolwich. The prevalence of scarlet fever last month showed a marked decrease from that recorded in the previous month; this disease was proportionally most prevalent in Finsbury, Shoreditch, Southwark, Camberwell, Deptford, and Woolwich. The Metropolitan Asylums Hospitals contained 1324 scarlet fever patients at the end of last month, against 1128, 1206, and 1400 at the end of the three preceding months; the weekly admissions averaged 159, against 160, 162, and 200 in the three preceding months. Diphtheria also was less prevalent than it had been in the preceding month; among the several metropolitan boroughs the greatest proportional prevalence of this disease was recorded in Fulham, Finsbury, Stepney, Bermondsey, Deptford, and Woolwich. The number of diphtheria patients remaining under treatment in the Metropolitan Asylums Hospitals at the end of the month was 720, against 801, 771, and 839 at the end of the three preceding months; the weekly admissions averaged 85, against 100, 102, and 120 in the three preceding months. The prevalence of enteric fever showed a slight increase over that recorded in other recent months; this disease was proportionally most prevalent in Paddington, Hackney, the City of London, Battersea, and Greenwich. There were 56 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 35, 33, and 47 at the end of the three preceding months; the weekly admissions averaged 10, against 5, 6, and 9 in the three preceding months. Erysipelas was proportionally most prevalent in Hackney, Bethnal Green, Stepney, Southwark, and Deptford. The 30 cases of puerperal fever notified during the month included 4 in Wandsworth, 3 in Fulham, 3 in Southwark, and 2 each in St. Pancras, Hackney, Stepney, Poplar, Bermondsey, and Woolwich. The 3 cases notified as cerebro-spinal meningitis belonged respectively to Kensington, Fulham, and Bethnal Green.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex- and age-constitution of the populations of the several boroughs. During the five weeks ending Sept. 2nd the deaths of 7790 London residents were registered, equal to an annual rate of 18·9 per 1000 of the population, against 13·2, 11·7, and 12·4 per 1000 in the three preceding months. The death-rates last month ranged from 10·5 in Hampstead, 13·6 in the City of Westminster, 14·6 in Paddington and in Stoke Newington, 15·4 in St. Marylebone, 15·6 in Woolwich, and 15·8 in Wandsworth, to 22·2 in Greenwich, 22·3 in Stepney, 22·7 in Hammersmith, 22·8 in Finsbury, 23·1 in Southwark, 25·3 in Bethnal Green, 25·9 in Shoreditch, and 26 6 in Poplar. The 7790 deaths from all causes included 64 from measles, 12 from scarlet fever, 46 from diphtheria, 72 from whooping-cough, 12 from enteric fever, and 2666 (among children under two years of age) from diarrhœa and enteritis. The lowest death-rates from these diseases in the aggregate were recorded last month in Chelsea, the City of Westminster, Hampstead, St. Marylebone, Stoke Newington, Holborn, and the City of London; and the highest rates in Hammersmith, Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, and Greenwich. The 64 deaths from measles were 57 fewer than the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal in Fulham, Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, and Greenwich. The 12 deaths from scarlet fever were less than one-third of the corrected average number, and included 4 in Islington, 2 in Hackney, and 2 in Camberwell. The 46 fatal cases of diphtheria were slightly above the corrected average number; among the various metropolitan boroughs this disease showed the highest proportional mortality in St. Pancras, Finsbury, Southwark, Lambeth, Greenwich, and Lewisham. The 72 deaths from whooping-cough were 11 below the corrected average number, the highest death-rates from this disease being recorded in Hammersmith, St. Pancras, Hackney, Holborn, Finsbury, Bethnal Green, and Deptford. The 12 fatal cases of enteric fever showed a slight decline from the corrected average number; 2 belonged to Islington and 2 to Greenwich. The 2666 deaths from diarrhœa and enteritis among children under two years of age were greatly in excess of the normal number; deaths from this cause were proportionally most numerous in Hammersmith, Fulham, Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, Deptford, and Greenwich. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases (excluding diarrhœa) was 31·3 per cent. below the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: R. Miller to the *Pembroke*, for R.N. Barracks; and W. A. Whitelegge to the *London*. Staff-Surgeon: A. La T. Darley to the *Victory*, additional, for disposal.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Captains to be Majors:—Francis S. Irvine, Frank G. Richards, Ernest B. Knox, John Matthews, and Patrick S. O'Reilly (dated August 17th, 1911). Arthur M. MacLaughlin, James A. Hartigan, James F. Martin, Edmund McDonnell, and Arthur H. Safford (dated Sept. 4th, 1911). Captain Frank H. Noke retires on retired pay (dated Sept. 20th, 1911).

Colonel W. G. Birrell, from Woolwich, has taken up duty as Administrative Medical Officer at Dover. Lieutenant-Colonel F. W. Caton Jones, commanding the Military Hospital at Quetta, has been selected for the increased rate of

pay under Article 317 of the Royal Warrant. Lieutenant-Colonel A. F. L. Bate has been transferred from Rawal Pindi cantonment to take charge of the Station Hospital at Kuldana. Lieutenant-Colonel J. J. C. Donnet, at present serving at Belfast, has been placed under orders to embark for service in the Straits Settlements during the forthcoming trooping season. Major C. A. Stone has taken up medical charge of the Military Hospital at Cosham. Major W. A. Woodside, adjutant of the Royal Army Medical Corps School of Instruction, East Anglian Division, at Ipswich, has been placed under orders to embark for service with the Northern Army in India, embarking on the transport s.s. *Dongola* from Southampton on Nov. 29th next. An exchange of position on the roster for foreign service has been sanctioned by the War Office between Major L. Way, serving at Cosham, and Major A. R. O'Flaherty, serving at Devonport. Major R. C. Lewis has been transferred from Chapel Bay to the medical charge of Carnarvon Camp. Captain W. F. Tyndale, C.M.G., from Dublin, has been appointed Specialist Sanitary Officer at Devonport, with effect from Sept. 28th. Captain A. C. H. Gray, from Belfast, has been selected for appointment as Clinical Pathologist at the Royal Infirmary, Phœnix Park, Dublin. Captain S. B. Smith, from Dublin, has been selected for appointment as Sanitary Officer at Belfast, in succession to Major E. P. Sewell, whose tenure of the appointment will expire on Sept. 22nd. Captain A. E. Hamerton, D.S.O., from London, has been seconded for special duty under the Colonial Office in Nyassaland. Captain L. L. G. Thorpe, from Shipton, has taken up duty at West Down South, Salisbury Plain District. Captain J. H. Brunskill, on completion of the course of instruction to promotion to the rank of Major, has been posted to the Dublin District. Captain W. S. Crosthwait, on termination of field training at Moore Park Camp, has joined the Military Hospital at Fermoy for duty. Captain J. C. G. Carmichael has been posted to Manchester. Captain F. P. Lauder has been transferred from the Aldershot to the Irish Command. Captain B. B. Burke has arrived home on leave of absence from duty on the West Coast of Africa. An exchange of position on the roster for service abroad has been approved between Captain A. F. Carlyon, serving at Devonport, and Captain M. F. Foulds, surgical specialist at Belfast. Lieutenant A. L. Foster has been transferred from Rawal Pindi to the Station Hospital at Kalabagh, Muree Hills. Lieutenant G. O. Chambers, from the Military Hospital at York, has been placed in medical charge of the troops at Moor Laws Camp. Lieutenant A. W. Bevis has been transferred from Chatham to the Military Hospital at Maidstone. Lieutenant J. K. Gaunt, from Cork, has been appointed for duty at Limerick.

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions of officers of the Indian Medical Service:—To be Surgeon-General: Lieutenant-Colonel and Brevet-Colonel William Burney Bannerman (dated July 26th, 1911). Majors to be Lieutenant-Colonels: Benjamin Hobbs Deare, Benjamin Curwen Oldham, Robert Bird, C.I.E., Sidney Browning Smith, George Hewitt Frost, Edmund Wilkinson, George Francis William Ewens, Charles Duer, Henry Stotesbury Wood, Thomas Walter Irvine, James Entrican, Walter George Pridmore, Charles Donovan, Jeremiah Penny, and Douglas Henry McDonell Graves (dated July 28th, 1911). Captains to be Majors: William Ernest McKechnie, Harry Diamond Peile, Douglas Henry Fawcett Cowin, William Hancock Tucker, Charles Stewart Lowson, Dugald Nairne Anderson, Nath Manmatha Chaudhuri, Archibald Currie MacGilchrist, John Wallace Dick Megaw, Cecil Maurice Goodbody, Robert Steen, Frederick Fenn Elwes, Ernest Albert Churchward Matthews, Lessel Philip Stephen, Leonard Gilbert, Thomas George Nesbitt Stokes, Harry Malcolm Mackenzie, William O'Sullivan Murphy, and Cecil Charles Murison (dated July 27th, 1911).

The King has approved of the admission of the undermentioned gentlemen to the Indian Medical Service as Lieutenants on probation (dated July 29th, 1911):—John Alexander Sinton, Denis Fitzgerald Murphy, Edward Randolph Armstrong, Charles James Stocker, Eric Edward Doyle, Cyril Macdonald Plumptre, Archibald Wallace Duncan, Edward Austen Penny, George Blenkhorn Harland, Leon Francis Brandenbourg, John Edward Scudamore, and Henry Lewis Barker.

The commissions of the following Lieutenants on probation have been confirmed with effect from Jan. 28th, 1911:—John Scott, Alister Ralph Speirs Alexander, Kanwar Indarjit Singh, Frederick William Hay, George Tate, Sidney Milverton Hepworth, Harry Slater Cormack, George Selby Brock, Krishnan Gopinath Pandalai, John Frederick Henry Morgan, Jyoti Lal Sen, and Charles Albert Wood.

Lieutenant-Colonel J. Lloyd Jones, Assay Master of the Royal Mint at Calcutta, has been appointed Assay Master of the Royal Mint at Bombay, in succession to Lieutenant-Colonel A. Milne. Major W. Young, civil surgeon at Cawnpore, has been appointed to hold medical charge of the Unao district. The services of Major F. H. Watling have been placed at the disposal of the Government for employment in the Jail Department. Major C. Donovan, Madras Presidency, has been permitted to extend his leave of absence home from India by the Secretary of State. The services of Major Pandit Praraylal Atal have been replaced at the disposal of His Excellency the Commander-in-Chief in India. Major C. R. Stevens, professor of anatomy in the Medical College, Calcutta, and surgeon to the College Hospital, has been granted leave of absence home from India for six months. Captain R. C. MacWatters has passed the higher standard examination in Pashtu. Captain E. C. Hodgson, health officer at Simla, has been selected to officiate as Assistant Director of the Central Research Institute at Kasauli during the absence on leave of Major E. D. W. Greig. Captain R. E. Lloyd has been nominated a Fellow of the University of Calcutta. Captain C. I. Brierly has arrived home on 18 months' leave of absence from India. Captain H. H. Thorborn has been appointed an Agency Surgeon of the Second Class and posted as Civil Surgeon to the Khyber Pass Agency. The services of Captain F. C. Fraser have been placed temporarily at the disposal of the Government of Madras. Captain C. A. Sprawson, civil surgeon, has been granted by the Secretary of State for India an extension of his leave of absence for one month on medical certificate. Captain N. E. H. Scott, officiating agency surgeon, has been posted, on return from leave, as Residency Surgeon at Bagdad and *ex-officio* Assistant to the Political Resident in Turkish Arabia. Captain H. R. Dutton, officiating civil surgeon at Purnea, has been appointed to act as Civil Surgeon of Muzaffarpur during the absence on leave of Major B. R. Chatterton. Captain J. McPherson, officiating agency surgeon, has been granted leave of absence home from India for 11 months. The services of Captain E. Bisset have been placed temporarily at the disposal of the Government of the United Provinces for plague prevention duty. Captain R. A. Needham has been selected for appointment as Medical Officer of Health at Simla during the absence on special duty of Captain E. C. Hodgson. Lieutenant F. F. S. Smith has been appointed Specialist in Ophthalmology to the Second (Rawal Pindi) Division of the Northern Army in India.

Major T. A. Granger, I.M.S., has been appointed secretary to the Principal Medical Officer to His Majesty's Forces in India, in the place of Brevet-Colonel H. F. Cleveland, I.M.S.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant Robert McC. Linnell is confirmed in his rank. Henry Meredith Buchanan to be Lieutenant (on probation) (dated 10th August, 1911).

THE IMPROVEMENTS IN THE NAVAL MEDICAL SERVICE.

Our contemporary, the *Broad Arrow*, referring to the changes recently made in the organisation of the medical branch of the navy, says: "Apparently the medical branch of the navy is in much the same position as the Army Medical Corps a generation ago. The recent reforms, well-intentioned as they are, do not go to the root of the matter. Until recognition of the medical man in the navy is as full as it is in the army the service will not attract good professional men in sufficient numbers. ..... If things are allowed to rest where they are we shall have as bitter an awakening in the next naval war as we had in the Crimea. In fact, the whole organisation of the medical branch wants to be thoroughly overhauled. ..... Many of the sanitary grievances of the lower deck, which give the Socialist agitator a chance, would be remedied if the medical branch were placed on a better footing. ..... But as the Admiralty has begun to move, perhaps it will continue the good work."

THE JAPANESE NAVAL MEDICAL DEPARTMENT IN THE RUSSO-JAPANESE WAR.

The *Archives de Médecine et Pharmacie Navales* presents in its August number the first instalment of a paper by Dr. Chemin, Médecin de Première Classe (as we would say, Staff-Surgeon), who is translating from the Japanese the fourth volume of the official history of the war of 1904–05, the volume which concerns itself with the work of the Naval Medical Department. At present he is dealing with the early battles of the war. In the third, the successful, endeavour to seal up Port Arthur 168 men were employed in the transports and their accompanying torpedo flotilla, of whom 46 per cent. were lost or killed and 15 per cent. were wounded. These latter were all on board a hospital ship by the second day following, and in Japan, in hospital, by the fourth day, so that the methods for handling the wounded were wisely planned and well executed. Collisions between ships and the explosions of mines destroyed one-sixth of the Japanese Fleet, whether number or size of ships be considered. Of the men of the ships which so foundered, 40 per cent. were lost, and 5 per cent. were wounded. So many men, wounded in the early destroyer attacks, died from their wounds that it was decided to put two hospital orderlies in each boat, except that of the divisional commander, to which a surgeon was sent. Not only the wounded were sent to the hospital ship, but also the bodies of those who had died. This article should be read by every naval surgeon.

The King has given to Surgeon James Campbell Bringan, R.N., His Majesty's Royal licence and authority to accept and wear the Insignia of Officer of the Order of the Crown of Italy, which decoration has been conferred upon him by His Majesty the King of Italy, in recognition of valuable services rendered by him on the occasion of the earthquake in Southern Italy in the year 1908.

During the presence of the Home Fleet in the Firth of Forth the Prince of Wales paid a visit to the Royal Naval Hospital at Butlaw.

Correspondence.

"Audi alteram partem."

SMALL-POX IN THE UNITED STATES: A DANGEROUS DOCTRINE.

To the Editor of THE LANCET.

SIR,—For a couple of weeks I have been keeping on my desk your issue of July 22nd, waiting for an opportunity to compose a suitable protest concerning your annotation on "Small-pox in the United States: A Dangerous Doctrine." In Dr. Trask's article there are, as the annotator painstakingly points out, a few sentences which, when carefully dissected away from the context, *might* be construed as giving aid and comfort to the antivaccinationists; but, read with the skill and care ordinarily bestowed on the reading of scientific articles, no such ideas would be conveyed; and at the worst the errors are not of the nature of "total disregard of logic," "non sequitur," &c., but are merely minor errors of rhetoric. The writer (Dr. Trask) has made it entirely possible for any fair-minded and otherwise sufficiently qualified reader to understand him, but has not quite succeeded in the Herculean task of making his article impossible of misinterpretation.

In the original article Dr. Trask was obviously trying to show that the great majority of small-pox cases in the United States are of an extraordinarily mild type, with a case-mortality of a fraction of 1 per cent., whereas the case-mortality in Germany, Japan, and elsewhere, as well as in certain brief and localised epidemics in the United States, runs up to the classical figures—namely, 15 to 50 per cent. or more—and that this low case-mortality in the United States indicates that the prevailing strain of small-pox here is in some essential particular different from small-pox in Europe and Asia and from the severe affection that occasionally breaks out in the United States. He supports this view with facts and arguments which your annotator perverts into the semblance of a "dangerous," "revolutionary," and "illogical" attempt to discredit vaccination! And this "in the face of such evidence, recounted by himself" (Dr. Trask) and quoted at length by the annotator, as to show that Dr. Trask thoroughly believes in vaccination as a measure of *individual* prophylaxis, and recognises that efficient *general* vaccination will stop even a virulent small-pox epidemic!

In the light of the annotation perhaps I can restate and enlarge on the propositions that have so badly confused the annotator in such a way as not to be misunderstood—at least, not in the same way as Dr. Trask was. This is highly desirable, because while the few careful readers of the Reports thoroughly understand Dr. Trask's views on American small-pox, these views are to-day misunderstood and discredited by thousands of physicians throughout the world, thanks to THE LANCET'S wide circulation and the annotator's misinterpretation.

1. It is true that in certain localities (e.g., *vide infra*) vaccination has been so efficiently performed that there is room for no other explanation of the rarity and mildness of small-pox; but no one familiar with *all* the known facts believes this explanation adequate to account (directly at least) for the almost invariably mild type of small-pox in the United States *as a whole*.

2. To explain the low case-mortality of small-pox in the United States we may assume either that the people are partially immune to the disease, or else that the prevailing strain of infection is greatly reduced in virulence, or both. There is little or nothing to show that the unvaccinated in the United States are for any reason more resistant to the killing power of small-pox than are the unvaccinated in Europe or Asia, who nevertheless appear to be from 10 to 100 times as apt to die when attacked. On the other hand, there is much to show that this low case-mortality in the United States is due to a lack of killing power in the infecting agent.

3. Such an immunity, if it exists at all, may be due to the cumulative results of vaccination or small-pox or other immunising influences as yet unknown, perhaps extending over several generations.

4. If the low case-mortality of the disease in the United States be entirely or in great measure due to an increase in the individual's resistance caused by vaccination or previous small-pox, we would expect that the cases among those not so protected would show the classical high mortality. On the contrary, the case-mortality is very low, even among the non-protected. No *resistance* theory applicable to the United States and not to other countries seems to have any facts to support it.

5. That it will not do to regard vaccination as a sufficient explanation for the low case-mortality of typical American small-pox is further shown by the history of several localities. Ordinary mild small-pox had been prevalent for some time, when suddenly, without any other appreciable change in the situation, high mortality epidemics broke out, which were cut short by efficient general vaccination. This indicates (first and most obviously) that efficient general vaccination will suppress even a virulent epidemic; and (secondly) that given the conditions as to small-pox protection usually existing in typical American localities, small-pox may be either (*a*) not present; (*b*) of the usual mild American type; or (*c*) very rarely of the old-fashioned severe type. In other words, it is almost certainly some factor operating on the community as a whole—some factor other than the desultory voluntary vaccination characteristic of English-speaking peoples to-day—some factor other than personal resistance of whatever nature—that determines what form of small-pox an infected American community is to have. In other words, this consideration further confirms the theory that variation in the seed rather than in the soil is the determining factor.

The "Public Health Reports" is *not* a widely circulated publication in the usual meaning of the term, although a few copies travel considerable distances. It is written and edited by and for professional sanitarians, and the bulk of its contents are the most somnifacient of statistics. Hence there would have been little danger of the anti-vaccinationists getting anything remotely resembling aid and comfort from this issue if it had not been for the painstaking assistance of THE LANCET!

I am writing this on my own initiative and responsibility,

without the knowledge of anyone in the service, least of all Dr. Trask.—I am, Sir, yours faithfully,

NORMAN ROBERTS,
Passed Assistant Surgeon, U.S. Public Health and M.H. Service.

Washington, D.C., August 24th, 1911.

*** Although we have already published in THE LANCET of August 19th Assistant Surgeon-General Trask's disclaimer of the significance that we attached to his original article in our annotation in THE LANCET of July 22nd, we print Passed Assistant Surgeon Roberts's letter. We do this because it does express clearly a position different from, but not necessarily exclusive of, the view that the careful perusal of Dr. Trask's article conveyed to us. A writer's meaning must be gauged by what his language does actually convey. What any writer intends to express is known only to himself and, perhaps, to some in personal touch with him. We have carefully re-read the original article as published in the Public Health Reports and our comment thereon, and we remain of the opinion that that comment, which Passed Assistant Surgeon Roberts calls perverse, was entirely justified from the material then before us. This opinion is strengthened by a reprint of Dr. Trask's article, in which the alterations from the original are so material as themselves to justify the construction that we placed on his original words. To give only one instance. In the original article Dr. Trask wrote (and we quoted the paragraph as part of our gravamen): "That the type of the disease as seen in the United States is due to the protective value of vaccination is shown not to be true for certain localities in which outbreaks of the virulent form of the disease have been reported." In the reprint this passage appears as follows: "That small-pox in the United States has become permanently mild has been shown not to be true for those localities at least in which outbreaks of the virulent form have been reported." Again, Dr. Trask, in his original article says: "To explain the small number of deaths in the United States, we may presume that either the people are partially immune to the disease or else that the existing infection is extremely mild and non-virulent." We asked, "Why, 'either ..... or else?' The two conditions are not mutually excluding." Passed Assistant Surgeon Roberts practically recognises this when in re-stating the same argument he adds the words "or both" to the proposition. The errors we cited do show, as we said, disregard of logic, their conclusions are "non sequiturs," and they are not merely errors of rhetoric, minor or otherwise, and oddly enough, Passed Assistant Surgeon Roberts, who reproaches us for this view, would appear to take it himself. We are glad to find that in the article as amended the meaning is clear. Our correspondent denies that the Public Health Reports are a widely circulated publication in the usual meaning of the term. Is it not the case that they are sent for comment to the principal lay press of the United States? Does not that press reach and influence the people of the United States?—ED. L.

A QUESTION IN EUGENICS.

To the Editor of THE LANCET.

SIR,—I hold no special *brief* for sterilisation, and the plan which I have always advocated for dealing with the "mentally deficient" is the following: The notification of these aments to the asylums committee of the county by the medical officers attached to the different schools. They would then be certified before a magistrate and be sent to some farm or industrial colony until the age of 21, when they would again be examined by some expert body appointed for the purpose and a decision arrived at as to whether they should be allowed out into the world, with or without sterilisation, or be segregated for life when no sterilisation should take place. The Lunacy Commissioners could be consulted on the subject, although it seems manifestly unfair to throw more duties on a body already overworked. The rich and poor should be notified, and the former, if they prefer, could have colonies of their own supervised by county officials.

A large number of paupers receiving outdoor relief are feeble-minded; these could be weeded out by the medical officers of the workhouses and segregated. The habitual criminal, the "mental alcoholic"—both degenerates—and the juvenile feeble-minded offender could be dealt with in a similar manner. These sections should be carefully classified and sent to separate colonies. This is a rough outline of the scheme I consider best and the details could be embroidered in. The main reason for making the age 21—it could be 18 in many cases—is that there is a large number of dull and backward children whose mental condition closely resembles that of feeble-mindedness, but whose state is really due to a faulty environment—lack of nutrition, &c.—and is not *inborn*. These under favourable conditions would become of average—maybe of more than average—intelligence, and could readily take their place in the world and in time beget healthy offspring. The plan will cost money, but just as an individual, when he is ill, does not object to dip deeply into his purse for the sake of health, so the nation should part freely with its wealth for the sake of national health. The Government is about to combat tuberculosis, why not degeneracy? It would be the truest economy in the long run. Taking the figures for last year, insanity has increased 262·2 per cent. on the figures for 1859, whilst during the same period the population has only increased 85·8 per cent.

Miss Dendy, the very able administrator at the Sandlebridge Colony, containing 225 feeble-minded boys and girls, has said that weakness of will in proper circumstances made for morality and for happiness; that if this class could be so easily guided into wrong in improper surroundings they could be equally well guided towards right in proper circumstances. A man has lately committed murder in London. What is his family history? Father an epileptic and a drunkard, mother insanity in her family and she herself a drunkard, the brother of the murderer in this asylum. Recently I have had occasion to take the family histories of the last 50 young females admitted here, ages from 15 to 25, non-imbecile and non-epileptic, not married and not mothers. What did I discover? 90 per cent. deeply infiltrated with insanity, epilepsy, tuberculosis, alcohol, and cancer. Take a family consisting of six children, two of whom were epileptics; these two should be prevented from begetting offspring; the other four, being apparently normal, need not be interfered with. Is this an unreasonable request? No one would knowingly breed from a diseased animal, and man, notwithstanding his high understanding, is yet essentially an animal. Surely nothing can be more wasteful than this army of degenerates.

To the medical profession public opinion entrusts the welfare of the race, and through this the destiny of the nation; therefore, it behoves us patiently to inquire into the causes of mental degeneration and fearlessly to recommend the remedy which, in my opinion, lies in eugenics. There are some who apparently fail to realise the great differences which exist between castration and vasectomy. Although I do not recommend castration I have always failed to understand why there should be such an outcry against the operation, for numerous *healthy* ovaries and testicles have been removed for the cure of *physical* diseases. If for the cure of physical diseases, why not for the *prevention* of *mental* diseases?

The crux of the whole question is this: Are the "unfit" producing children at the rate of 7 per family and the "fit" at the rate of 3? If this is so, it is not necessary to be much of a prophet to foretell the result, for the bedrock of heredity is that "like tends to beget like," and through the continuity of the germ plasm we obtain continuity of resemblance from generation to generation. Figs do not grow on thistles nor grapes on thorns. Environment can but develop or crush that which heredity impresses on the germ plasm; it is not creative, and is to heredity what manure is to a plant. But good and favourable conditions are absolutely necessary for the proper development of every living organism.

The eugenic rules may be summarised into three (Professor J. A. Thomson): (1) The mentally and physically healthy should be mated; (2) a markedly good constitution should not be paired with a tainted one, for this would be wanton

waste; and (3) every precaution should be taken to prevent a badly tainted stock from diffusing itself. A race which ceases to insure that its better elements have a dominant fertility destroys itself far more effectively than its foes could ever hope to do on any battlefield.

The highest gift which has been bestowed on man and woman is the *creation of life*, and do we not stand condemned when we deliberately permit degenerates to curse their offspring with a mental disease which will cause untold misery to many generations? Pity is the highest and most exquisite of human emotions, and surely the *prevention* of suffering is more noble than its *creation*.

I am, Sir, yours faithfully,
C. T. EWART, M.D. Aberd.

Claybury Asylum, Sept. 9th, 1911.

To the Editor of THE LANCET.

SIR,—The correspondence which has lately taken place in THE LANCET shows that not a few have failed to grasp the proposals I made in 1903. In no case have I proposed that either the ovaries or testes should be removed. I proposed three slight operations: (*a*) vasectomy—dividing and ligaturing the vasa deferentia; (*b*) spermectomy—dividing and ligaturing the entire spermatic cords; and (*c*) fallectomy—dividing and ligaturing the Fallopian tubes. Since then Dr. Sharp of Indiana, U.S.A., has proposed that the testicular end of the vas should not be ligatured, so that the spermatic fluid might infiltrate the local tissues and be absorbed. So far as we know, when vasectomy is performed there remain (1) sexual desire; (2) sexual power; but (3) no power to impregnate. With spermectomy all three disappear; with fallectomy there are sexual desire and power, but no power to conceive.

Some cases have been published where it has been alleged that women have become pregnant after the tubes and ovaries have been removed. My theory regarding this is that since we have so far no knowledge of what number of hours, days, or months the ova may remain in the uterus before impregnation takes place, therefore, the ova may be resting there *before* the operation has taken place. We know more about the vitality of the spermatozoa longevity. No doubt when vasectomy has been put more fully into use we shall have cases where impregnation has taken place after the vasa have been ligatured. But this will be due to the sperms contained in the vesiculæ, or because of female polygamy. This is one reason why, when possible, vasectomy should be performed early in life. I further proposed that sterilisation should be divided into voluntary and compulsory. The former would apply to tuberculosis, cancer of the womb, deformity of the pelvis, and other physical and mental conditions where two or more practitioners could certify that the parental diseases were incurable. It is instructive to find Dr. Sharp relating that of some 1000 criminals sterilised over 500 demanded to be so operated upon. I think a very large proportion of degenerates suffer so greatly that their lives would be a little brightened if they knew they would not curse their children with their incurable defects. Under compulsory sterilisation I propose to include idiots, imbeciles, feeble-minded, sane and insane epileptics, lunatics, sexual perverts, habitual inebriates, drug habitués, prostitutes, chronic vagrants, and habitual criminals. Such a list will be found in the second edition of my work, "Race Culture; or, Race Suicide."

May I suggest that it would help to clear our ideas if THE LANCET appointed a committee to inquire into and report upon the alleged secondary secretions of the testes and ovaries. For so far we seem to have obtained most of our knowledge (?) from the various drug manufacturers and from quacks. I am, Sir, yours faithfully,

Liverpool, Sept. 10th, 1911. ROBERT R. RENTOUL.

To the Editor of THE LANCET.

SIR,—Perhaps you will admit a belated note from a correspondent who, being abroad, has only just seen this controversy as far as your issue of Sept. 2nd. The question as originally put was unanswerable, because sterilisation by castration and by vasectomy or salpingectomy was regarded as posing the same moral issue. The former operation has well-known consequences to body and mind; the latter affects no function or appetite or capacity, but merely makes parenthood impossible. But the question, as put, has led most of your correspondents to condemn sterilisation on the ground that it means castration.

Castration was never contemplated by Sir Francis Galton; it has been repeatedly repudiated by myself in lectures to the Sociological Society and the Eugenics Education Society; Mr. Havelock Ellis has done likewise, and has explained the (exceedingly obvious) difference between castration and vasectomy in the *Eugenics Review*, and will shortly do so again in one of the "New Tracts for the Times" which are about to appear.

Dr. Waller has thus occupied a column and a half of your space with entirely irrelevant considerations. He cannot name one "crack-brained exponent of eugenics"—to quote his courteous phrase—who advocates what he condemns; but the names of its slack-brained opponents are legion.

I am, Sir, yours faithfully,
C. W. SALEEBY, M.D. Edin., F.R.S. Edin.

Scheveningen, Sept. 15th, 1911.

PELLAGRA IN EGYPTIAN PRISONS.

To the Editor of THE LANCET.

SIR,—In your review of the late Sir Eldon Gorst's report on Egypt and the Soudan in 1910 (THE LANCET of August 19th, 1911, p. 539) I notice the statement that bread made from maize has been substituted for wheaten bread in the prisons, and that "evidently there is no official belief in the view that this change of diet may increase the cases of pellagra among the prisoners." It seems probable that the latter remark is due to a misunderstanding as to the kind of maize used in the prisons, which in reality is the small kind usually called millet or "durrha Owaiga." The large-grained durrha called "durrha Shamy," or "Indian corn," or simply "maize," is not used in the prisons' diet. So far as I know the former kind (millet) has not been inculpated as a cause of pellagra. As what is ordinarily called maize is not used in making bread in the prisons in Egypt at all, any pellagra that may arise in the prisons cannot be ascribed to the change from wheaten bread, unless of course millet is also believed to be a cause of pellagra.

I may add that in the Report on the Prisons of Egypt for 1910 Dr. R G. Kirton, the principal medical officer, writes on p. 18 that the use of maize bread was not allowed, partly because of its supposed causal relation to pellagra, but that millet was selected to replace wheat. In view of the rival theories as to the causation of pellagra, it may be worth while to record the actual facts in the case of the Egyptian prisons. I am, Sir, yours faithfully,

J. WARNOCK,
Director, Hospital for the Insane, Abassiah.

Cairo, Egypt, Sept. 8th, 1911.

TOXIC EFFECT OF ASPIRIN.

To the Editor of THE LANCET.

SIR,—I have long been anxious to see a case of aspirin poisoning as described by your correspondent Dr. Alexander Brown, in THE LANCET of Sept. 9th. Perhaps he or others of your readers who may have met with similar cases can tell us whether the patients presented symptoms characteristic of minor thyroid inadequacy. The symptoms I refer to are subnormal temperature, hypersensitiveness to cold, liability to chilblains, marked dental caries, general muscular asthenia with sensation of fatigue, and constipation. In view of Leonard Williams's researches we must also accept the presence of enlarged tonsils or adenoids (past or present) and nocturnal enuresis as equal evidence. Any rickety symptoms must also be added to the list, and among these must be included the contracted palatine arch; nor must one forget to include goitre, inasmuch as this is clear evidence on the part of Nature that the supply of thyroid secretion is inadequate. In the case of Graves's disease the secretion is doubtless from some points of view excessive, though possibly even here there is some insistent demand for secretion which may be the hidden cause of the disease. Many other individual symptoms may need to be considered in weighing the merits of a given case of thyroid insufficiency, and such symptoms must be gleaned from those of myxœdema, cretinism, and other conditions in which thyroid medication has proved so valuable. Naturally they will not *all*

be found in every case of *minor* thyroid inadequacy. But the point of my inquiry is this.

The symptoms of aspirin poisoning are practically the same as those of urticaria major or angioneurotic œdema, of which I have only treated two cases. The first was before I had experience of the power of thyroid medication, and though I patiently administered calcium lactate I was distinctly disappointed in the results, and the patient was subject to frequent and sudden attacks of an alarming nature. The mucous membrane of the cheeks and fauces was several times so affected as to make respiration difficult and swallowing almost impossible, and we were constantly prepared for tracheotomy. The lips and eyelids were often so swollen and red as to make the patient unrecognisable, and wheals of urticaria the size of the palm of the hand would appear on her limbs or body. She eventually got well and was lost sight of after about six weeks, but calcium lactate alone did not prove to be the panacea I looked for. The second case was similar but less intense. The patient was 25 years of age, and had been subject to these attacks for three or four months when I first saw her, but in her case the urticaria never lasted more than an hour or two. Thinking that her general condition warranted me in classing her among the thyroid deficients, I gave one grain of thyroid extract three times a day with calcium lactate. The attacks of urticaria rapidly lessened both in frequency and intensity, and after three weeks disappeared for good. Thyroid medication was continued, and the general health improved so much that in about a couple of months all treatment was left off, and the patient has remained well since. The results in this case warrant one in thinking that urticaria major was attributable to thyroid deficiency. It would therefore be extremely interesting to know whether those patients in whom a dose of aspirin speedily provokes a similar condition are not also thyroid deficients, especially in view of the apparent antagonism between salicylates and thyroid secretion to which I drew attention in a recent article. Naturally one would not infer that a single dose of aspirin could produce urticaria or angioneurotic œdema in a few moments by direct action on the thyroid gland, but it is not difficult to suppose that the presence, or absence, of an adequate supply of thyroid secretion in the blood may so modify the condition of the latter (possibly *viâ* the calcium coefficient) that the normal individual can take aspirin without getting angioneurotic œdema, whilst the thyroid deficient might be unable to do so. Have any of your readers administered aspirin to cretins or to patients suffering from myxœdema, and, if so, with what results? The answer to this question may throw some light on the matter, though, again, there are obvious differences between myxœdema and minor thyroid inadequacy.

I am, Sir, yours faithfully,

H. EWAN WALLER.

Moseley, Birmingham, Sept. 15th, 1911.

THE RADIO-ACTIVITY OF SEA-WATER.

To the Editor of THE LANCET.

SIR,—The very interesting letter by Dr. Sidney Russ which appeared in THE LANCET of Sept. 16th does not, if I may be pardoned for saying so, quite clear up the physical side of the question.

It is, I believe, admitted that the water from many radio-active springs loses its activity rapidly on being bottled. Such water, if examined after several months, may perhaps be shown to contain minute quantities of actual radium salt in solution, but the amount of radium permanently present cannot be taken as a measure of its activity when drunk at its source. How the extra quantity of emanation—over and above the amount formed by its dissolved radium salt—gets into the spring water, I do not pretend to say. But it is at least theoretically conceivable that ocean water may be similarly charged when freshly collected.

Only a careful determination of the quantity of emanation present in freshly gathered sea-water (obtained as described by Robert Simon) with the amount contained in old samples can settle the matter. This determination presupposes great technical skill and the command of delicate apparatus. It is essentially a problem for the trained physicist and not for the physician. All that the latter can do is to point out that, physiologically and therapeutically, sea-water behaves in the same manner as water rendered temporarily radio-active by dissolved emanation—i.e., by a gaseous and rapidly decaying radio-active body, present apart from, or in addition to, radium itself.

I am, Sir, yours faithfully,

F. HERNAMAN-JOHNSON, M.D., Ch.B. Aberd., R.N. (retired).

Bishop Auckland, Sept. 16th, 1911.

TO MEDICAL FREEMASONS.

To the Editor of THE LANCET.

SIR,—May I again, through the medium of your widely read columns, appeal to medical men, and medical Freemasons in particular, for votes for the Masonic charities? At the forthcoming elections there are three medical candidates. Votes for any of the Masonic institutions are equally acceptable, as exchanges can be effected, and will be gratefully received and acknowledged by me.

I am, Sir, yours faithfully,

WILLIAM WILSON,
Secretary, St. Luke's Medical Lodge of Instruction.

184, Goldhawk-road, W., Sept. 19th, 1911.

EMOLUMENTS IN THE INDIAN MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—Having read your annotation in THE LANCET of July 15th, p. 171, entitled, "Emoluments in the Indian Medical Service," and some of the letters published from time to time in your correspondence columns, I venture to express my opinions on some of the points raised therein.

1. With regard to the contention that private practice is obtainable in most places—so it is, to the maximum value of £20 to £50 a year. The truth is that for 90 per cent. of civil surgeons there is really no private practice available. The remaining 10 per cent. are the men in the "plum" billets, who, naturally and rightly, are mostly senior men or those having special qualifications. The reason why nearly all Indian Medical Service men are so anxious to obtain civil employment is that there are excellent opportunities for good professional work. Moreover, a civil surgeon is his own master to a greater extent than is any other "district" or regimental official, probably.

2. It is not correct to say that a young officer has usually to wait eight or ten years before obtaining civil employment. The length of time varies from about three up to about ten years. Naturally one has to wait longer for the more popular provinces.

3. With regard to the remark of one of your correspondents that the purchasing power of the rupee had halved and the cost of living doubled, or words to that effect, I do not agree. No doubt its purchasing power has decreased, but pay has been increased. The real truth is that it is the fashion to use many articles of European manufacture nowadays, the price of which is necessarily high, as compared with similar articles of indigenous origin, and that consequently even a "fair wage" does not go far. If people care to, they can easily ride country-bred ponies instead of expensive "walers" and arabs, and have country-made cloth made up by the local "darzi" into "knockabout" suits which are quite good enough for every-day wear, &c. That polo and shooting are becoming the sports of rich men hardly seems to me to be a legitimate "grouse," even if true. I doubt if it is absolutely true, and think that the following instances support my contention. Firstly, I know a subaltern in a British regiment who plays polo and pig-sticks and occasionally shoots big game (he shot a tiger two years ago, has played polo for his unit, and has killed many pigs this season). He gets only a very small allowance. Secondly, I once served with a native infantry regiment which had been "runner up" to a British cavalry regiment in an open tournament. I doubt very much whether any of the British officers of that regiment had any private means whatever, but their mess was run on very economical lines, and they did not drink champagne or smoke expensive cheroots.

4. With regard to the numerous transfers in the early years of a man's service, travelling allowances are given

which will cover or nearly cover the expenses of a bachelor, and if men will be such fools as to get married before they have made for themselves a position which justifies the keeping of a wife, it seems to me that they ought to be prepared for hardships. As a matter of fact, these long transfers are educational, in my opinion, as one sees new races and manners. I speak from experience, having three times been transferred from one end to the other of the empire as well as having had other transfers of 1000 miles or so.

The general advantages of the Indian Medical Service are enormous. I will enumerate some of them in general terms, premising that there are differences between the military and civil sides, generally to the advantage of the latter. 1. Pay at more than a "living wage" from the beginning. 2. An extremely liberal scale of pensions, the first of £300 a year on completion of 17 years' service, rising every year thereafter *and available at every intermediate year* to £700 on completion of 30 years' service, with the possibility of increased pay and rates of pension if administrative rank is obtained. All privilege leave, furlough, &c., are reckoned as service for pension. 3. One year's holiday for every three years' work with special allowances for and extra furlough for study. 4. A variety of work and appointments so that the most diverse temperaments and capabilities can get the sort of "job" they like and "scope" which the average man would not get in a more highly developed country. For instance, such diverse appointments as the following: sanitary commissioner of a province, consultant physician or surgeon, bacteriologist and public analyst, pathological research appointments, superintendent of a jail or lunatic asylum, &c. Here I may note that I know of the case of an officer of about 35 years of age and less than 12 years' service who, subject to the control of the Government, has the sanitary destinies of 22 million people in his hands and draws a salary of about £1000 a year. He is a "good man," of course, but not a genius. 5. The privilege that the men with whom you have to work are as a rule educated gentlemen of your own social class. I should here like to quote from a letter I recently received from a very senior Indian Medical Service officer. He says:—

> I have had no "grouses" whatever against the service, and I can strongly recommend it to any keen young medical man, even now that the outlook may not be as hopeful as it was 32 years ago. I think perhaps to the confirmed "grouser" the best thing is to refer him to the many men of about his own calibre who were students with him at home and compare the lives they have led and the fortunes they have made with that of their contemporaries who elected to go into the I.M.S. If this does not convince him of some of the advantages of the I.M.S. all I can say is nothing will and discussion is useless.

Let me also detail the experiences of an intimate friend in the Indian Medical Service. He is not yet 33 years of age, nor has he completed ten years' service. He is an average man without special qualifications. He has had a sister out to the country and has paid the greater part of the expenses of a long university education for a younger brother. He has been able to spend between £200 and £300 on his own interests and amusements, such as scientific apparatus, books, horses, &c. He has had two holidays of three months each and one of six weeks, and his life has been insured for several years past for well over £1000. He is engaged to be married shortly, and if he dies on the day of his wedding his widow will get a pension of about £120 a year, and he has got no debts. Is it likely that he could have done, and enjoyed, so much in any other medical service or in private practice?

Now as to the disadvantages. These are very real, and some of them, such as those due to the climate, one does not fully realise till one gets older, when they entail separation from wife, children, and friends. The less obvious disadvantages are none the less real. They are undoubtedly affecting the recruiting of most of, if not all, the Indian services. They tend to increase and not to diminish as time goes by. As they are of a political nature, and I am an officer of the Government, I do not care to say much more about them, but the position may be summed up in the words of a distinguished junior officer of the British Army, since retired, which he uttered to me just before he left India for good. These were, "In my opinion, this country will be no place for a self-respecting white man in ten years time." I do not intend to reply to rejoinders, because this letter is not written to call "grousers" to repentance, but to show that the Indian Medical Service is not entirely composed of such.

Finally, Sir, I must apologise for the length of this letter, but the nonsense one sees written by "grousers," who often ignore the real difficulties of the situation, must be my excuse.

I am, Sir, yours faithfully,

August 28th, 1911. CIVIL SURGEON.

TUBERCULOUS PERITONITIS WITHOUT ASCITES, APPARENTLY CURED BY INCISION.

To the Editor of THE LANCET.

SIR,—The notes of the accompanying case were taken at the patient's bedside over ten years ago, and the case had gone out of my mind when I met the anæsthetist who assisted me, and we talked the incident over, coming to the conclusion that the case should be published, as in similar circumstances similar means might be taken in an apparently hopeless case. Although I have since the date of this case operated on several cases in which ascites was present I have not had a case of tuberculous disease of the peritoneum witnout ascites being present. No doubt many such cases have been treated by incision, though I have not come across any account of them, and none of the surgeons to whom I have described the case has had a similar experience.

I was called on June 10th, 1900, to see a boy, aged 14 years, who had been attended for about five months by the medical officer to his club, who had told the parents that he could do nothing further, and warned them to expect his death in less than a week. I admit that I felt he was not far out in his prognosis. The patient was practically skin and bone; he was lying on his back in an apathetic condition, from which he was aroused at frequent intervals by pain in the abdomen. His pulse was 120, his temperature 99·8° F. He had frequent attacks of diarrhœa, with constipation at intervals of a few days. The abdomen was distended, very tender on light percussion, tympanitic, with no dulness in the flanks. Food caused him pain, and apparently nearly all the best-known artificial foods had been tried.

At the end of a week he improved to the extent of losing a great deal of the pain and the abdomen became less distended and generally rigid and retracted. The temperature varied between 101·6° to 99°, and he took more interest in his surroundings, but this improvement did not last long. It was due, I think, to a more rigid system of dieting, for he was given food every two hours, and plasmon was given with the other foods. But by the end of June he was to all appearances slowly dying, and it then occurred to me that an experimental incision through the abdominal wall could do no harm and might possibly do good. On July 4th, under A.C.E. administered by another doctor, I made a small incision below the umbilicus. The peritoneum was thickly studded with small sago-like tubercles, both on the visceral and parietal membranes. I introduced two fingers through the opening and gently separated such adhesions as I could reach; not a trace of fluid in the peritoneal cavity was found. The wound was closed with silkworm gut sutures and not touched for about 11 days. There was an obvious improvement in the first day or two in his general condition. The temperature became normal and stayed normal, the bowels became more regular, the appetite came back, and I see by my notes on August 6th I lent him some volumes of the *Strand Magazine*. He continued to take his food well, and I persevered with the plasmon. On Sept. 10th he weighed 4 st. 10 lb., the average weight of a boy his age and height being about 6½ st. What he weighed when I first saw him must at a guess have been under 4 st. By Oct. 10th he weighed 5 st. 1 lb. On Oct. 22nd he did not seem so well, so I weighed him and found he had lost about 2 lb. Investigation showed that he had not taken plasmon for nearly a fortnight; this was resumed, and my next note, dated Nov. 5th, gives his weight as 5 st. 3 lb. A fortnight later, Nov. 19th, the gain on this was 4 lb.—viz., 5 st. 7 lb., at which he remained on Dec. 3rd. He continued the plasmon. On Dec. 17th he weighed 5 st. 10½ lb., and at my last visit on Dec. 22nd his weight was 6 st. 1 lb. I marked him cured and took him off my list.

I learnt that he had taken a place as errand boy to a grocer either at the end of January or beginning of February and was keeping quite well. I showed the patient and read a few short notes on his case at one of the local meetings of the Eastern Division of the British Medical Association in

November or December, 1901, a year after his care. He was perfectly well, and may, for all I can tell to the contrary, be alive and well to-day. It seems impossible to doubt that this boy's life was saved by the simple incision. How it could have acted I do not profess to know. I also consider that the plasmon was a great help, and the two noted occasions when it had been discontinued—on one he lost weight and on the other the weight remained stationary—were to my thinking more than a coincidence; that is proved by the increase of weight when he returned to his regular quantum of the plasmon.

I am, Sir, yours faithfully,

Sept. 15th, 1911. A. H. M.

TATTOOING *v.* VACCINATION.

To the Editor of THE LANCET.

SIR,—Since I wrote the letter which appeared in THE LANCET of August 26th, I have been told by an elderly ex-officer (not medical) of the Indian Army that in his day he was aware of a belief among the Burmese that tattooing was a prophylactic against malarial fever, but that he had not heard of it as a substitute for vaccination. The point, however, to which I called attention, and as to which Mr. J. Y. W. MacAlister has corroborated me, is that British medical officers appear to inculcate the belief among British soldiers serving in India that tattooing protects against small-pox. Do they or any of them admit doing so, and if so, on what grounds do they do it?

I am, Sir, yours faithfully,

Sept. 16th, 1911. E. A. A.

THE ORGANISATION OF THE MEDICAL PROFESSION.

THE POSITION IN NORTHUMBERLAND AND DURHAM.

(FROM OUR SPECIAL COMMISSIONER.)

Newcastle, Sept. 18th, 1911.

TEN years ago the medical practitioners of the counties of Durham and Northumberland were in open revolt against the system of contract work then prevailing. Without organisation, however, there was little or nothing to be done. At Gateshead an association had been formed, and there was in Newcastle a Medical Ethical Society. It was in August, 1900, that the first and not very successful attempt was made to form a union of the Northumberland medical practitioners, much on the same lines as that of the County of Durham Medical Union which was already in existence. The movement grew and was fortunate in securing for its president Mr. Rutherford Morison. As a leading surgeon and consultant Mr. Rutherford Morison had no personal interest whatsoever to serve, and this gave a great moral force to his arguments, whether addressed to medical practitioners or to the medical aid organisations by which they were employed. By the end of the year 1900 a union had been formed of Northumberland practitioners, and it amalgamated with the existing Newcastle Medical Ethical Society. The next year the newly created Medical Union was already engaged in numerous disputes throughout the district and several medical strikes took place. Details concerning this organisation and struggle were published in these columns at the time. There were 350 practitioners in Northumberland, and before the expiration of one year 171 had joined the Medical Union. In the course of time the union gained further strength, and after many struggles overcame all resistance so far as the colliery districts are concerned. Formerly a collier paid 6*d.* a fortnight for medical attendance on himself and family. This is now uniformly raised to 9*d.* through the action of the union. The pitmen in Northumberland are very loyal to their trade union, and the medical practitioners made a great point of this fact. They freely called the imported medical men blacklegs, and appealed to the pitmen to allow that the medical practitioners had equal right to form a union of their own and oppose strike-breakers.

In the county of Durham there has not been the same measure of success. It seemed more difficult to bring the colliers and the medical practitioners into line. Then the settlement effected in the towns was not so satisfactory. Here there are a multitude of insurance companies and clubs of all sorts. Some of these only paid 2*s.* 6*d.*, and very few paid more than 3*s.* 6*d.* a year to their medical officers. At Newcastle the conditions have been raised to a uniform 4*s.* a year. This, however, is not satisfactory because the capitation fee is not high enough and because the 4*s.* arrangement has not a retrospective effect. Those who are working for less continue to do so, and it is only on their posts becoming vacant that the 4*s.* minimum payment is to be applied.

The Problem of National or Local Union.

After these results had been attained a grave problem presented itself. The constitution of the British Medical Association was recast, and the question arose as to whether the fighting unions formed in various parts of the country should join the British Medical Association now that it gave promise of taking an active part in the economic questions that so deeply affect the material welfare of the majority of medical practitioners. Of course, the larger the union or association the greater its power if it can be made to take action, but the larger the body the more apt is it to become inert. However, the Northumberland and Newcastle Medical Union resolved to join, and a year later the County Durham Union followed this example. It was arranged, however, that, while merging with the British Medical Association, these local bodies were to retain the organisation they possessed and their officers, only instead of being isolated county unions they were to be the county committees of the general association or union. But, and this is perhaps where in practice the greatest difficulty has arisen, these old, well-tested societies, these veterans in the fight, were to become sections, within the North of England Branch of the British Medical Association, and it was felt that the activity of the old Durham and Northumberland Unions would be somewhat compromised by the comparative inertness of the larger local body of which they were now to form part.

Arrival of the National Insurance Bill.

As an example of this inertness, when the National Insurance Bill came before the public nothing was done by the branch at once. The old unions, it is claimed, would have taken up the question energetically but could not do so now, and the North of England Branch of the British Medical Association did not. Therefore, as the leaders and officials did not move, the mass took action without order and without leadership. Independent practitioners of their own initiative convoked a meeting, and that they were justified in their action was proved by the fact that some 300 medical men attended. Many members, of course, of the existing organisations were present, but they came as individuals. This meeting eventually decided to support the conditions which the British Medical Association had laid down in regard to the Insurance Bill, this being before Mr. Lloyd George had consented to give over the control of the medical services to the Health Committees.

Amalgamation of Local Medical Unions with the British Medical Association.

It is necessary to explain that the position in Northumberland and Durham was altogether exceptional. The unions which medical practitioners had formed to fight the clubs and medical aid associations before the alteration of the constitution of the British Medical Association were for the most part confined to one town and its immediate neighbourhood. It was easy to assimilate these smaller bodies with the local divisions of the British Medical Association, when they would still maintain to a large extent their former identity. The various bodies and committees of many old medical unions were maintained in the divisions of the British Medical Association, and their scope of action was enlarged by being able to send representatives to the meetings of the nearest branch, which would perhaps comprise several counties. There is strength in such an enlargement, but there is weakness also. All these secretaries of divisions are under the branch, and if the management of the branch is unsatisfactory then all the local bodies suffer in consequence. Formerly a local body failed to progress or to hold its own if its secretary and committee were not up to the mark; now all the local bodies, however competent in themselves, may suffer through the branch by which they are dominated. In regard, however, to Northumberland and Durham, the professional

unions formed in these counties were so large and important that the by-laws of the British Medical Association had to be specially modified so as to meet their case. A new hierarchy had to be created. It was agreed that the old unions, their committees and secretaries—in fact, the whole of the machinery which had been so admirably constructed and with which so many victorious battles were fought—should be maintained. Only instead of being called unions, and as they were too big to become divisions of the British Medical Association, it was decided that they should be known as the Northumberland and Newcastle Committee and the County Durham Committee. But these committees, as is the case with the divisions, were placed under the North of England Branch. Two years ago, when the annual meeting of the North of England Branch took place, no measures were taken to elect the Northumberland and Durham committees. The most vital and the most victorious organisations of this part of England were thus unfortunately flouted. Naturally a feeling of resentment has been engendered, which after smouldering for two years has now come to a head.

Feeling against the Suggested Suppression of the Old Unions.

The North of England Branch held its annual meeting at Sunderland on Sept. 14th, and I can testify that it was rather a stirring occasion. The programme as arranged consisted of business, lunch, golf, and a sailing excursion. The council of the branch met for a short time before lunch, and I am informed, for I was not present, that it was a stormy meeting. The President was instructed not to sign the minutes, and much dissatisfaction was expressed. Lunch followed, and time did not permit a further meeting to be held before the golf and the trip on the Tyne. On the other hand, those present at the meeting were determined that matters should not rest; therefore no officers were elected and no business was accomplished. It was all adjourned to another general meeting of the branch, to be convoked for that purpose and that purpose alone, early in October, to be held at Newcastle, a town which is much more accessible to the majority of members.

The Harm that has been Done.

Before concluding with this subject, and so that its importance may be better understood, it would be appropriate to give some indication of what has been lost through the effacement of the great northern medical unions. There have been a good many colliery strikes. The miners of course could not pay their medical attendants, though, if anything, there would be more rather than less illness among them. The colliery surgeons found that their incomes stopped entirely so long as the strike lasted. In this urgent position no practical steps were taken. Some of the colliery surgeons had sufficient influence with the miners to obtain extra payments when the strike was over so as to make up for the arrears accruing during the strike, but other medical practitioners obtained nothing at all, and had to work during the whole period of the strike without any payment whatsoever.

Formerly the consultants were brought into close connexion with the general practitioners through an ethical committee on which both sides were represented. The consultants in the early days of the struggle had very naturally urged that they were not going to ostracise and refuse to consult with some fully qualified practitioner because he had been condemned by a union of which they were not members. Before taking such an important step they wanted to know what it was all about. Therefore this joint committee of consultants and practitioners was formed and still exists, but apparently no longer works. As a result the list of blacklegs is no longer up-to-date, and many regrettable errors have consequently taken place. An eminent consultant related to me that on one occasion he had been telephoned to consult in regard to a patient living some distance from Newcastle. But he fancied the practitioner who sought his assistance was on some professional black list, so he telephoned to inquire from a colleague at Durham who was likely to know. The answer was that even to ask such a question on the telephone was absolutely libellous, while the only answer that could be given was that "the man ought not to be there." This clinched the matter, the Newcastle consultant refused to go, and at once informed all his colleagues of what he had done. Consequently they all likewise refused to consult with the practitioner in question. The important point is the sequel of the story. The practitioner thus boycotted was a very honourable and loyal member of a medical union; it was all a mistake, a deplorable mistake. On another occasion a consultant had received patients from, and written letters of advice to, a person who was certainly not on any black list because he was on no list at all. He was simply an unqualified practitioner. In the old days, when the medical unions were in full activity, such errors could not have happened, and the Northumberland and Durham practitioners are determined to bring them into activity again. If this can be done in coöperation with the British Medical Association, well and good. The principle of joining and participating with the work of the larger and national organisation is approved, but not to the point of sacrificing local activities.

When Does a Collier's Son Cease to be a Child?

The 9*d*. the miners pay per fortnight for medical attendance on their families includes of course the children. But when does a child, in this respect, cease to be a child? When the sons commence to work in the mines are they still to be considered as children? It is suggested that when 16 years old they should pay as adult unmarried males 6*d*. per fortnight. There is no general rule, nor will it be possible to establish such a rule till general action is taken.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Health of Liverpool: The Decline of Fever.

THE efforts made by the housing committee of the city council in rehabilitating the slums of the city are worthy of all praise. An inspection of the areas abutting on Great Howard-street, Vauxhall-road, and Scotland-road, recently made by the members of that committee, showed beyond all demonstration that unhealthy property has been transformed into light and airy tenements, based on up-to-date sanitary principles. It is an axiom that environment has much to do with the formation of character. Given better home conditions, a man or woman becomes more enlightened as to his or her responsibilities and as to the duties of citizenship. Since the demolition of insanitary property, now proceeding during the last 10 years or more, the convictions for drunkenness in the improved areas have been reduced, in some cases 50 per cent. The work of the municipality in this direction must be regarded as a means towards the mitigation of the strife and hooliganism for which Liverpool, unfortunately, has such an unenviable reputation.

At the proceedings of the health committee, which were held on Sept. 14th, the medical officer of health reported that the death-rate for the week was 27·2 per 1000, compared with 15·3 per 1000 in the corresponding week of last year. The statistics showed that during the week 130 deaths had taken place from diarrhœa, as against 30 in the corresponding week of last year. There are only 18 patients in the city hospitals suffering from typhoid fever. Special precautions are constantly taken by the health department in the matter of washing out the courts and alleys by means of disinfectants.

A report by the medical officer of health on hospital accommodation in Liverpool states that the number of beds at present available in the six hospitals is 1104. The value of the city hospitals and the immense amount of useful work performed are shown by the fact that no fewer than 6608 patients were treated within their walls during the year, the great majority being cases of scarlet fever. The advantages of the hospitals are now so fully recognised by the public that the removal to hospital of their sick dependents is insisted upon and claimed as a right. A few years ago, in cases similarly circumstanced, removals would never have been sought and would even have been resisted. Attention is drawn to the remarkable drop in the fatality from scarlet fever in the city during the last 60 years, due, in part at least, to hospital provision for the isolation of patients and to better administrative methods. The death-rate of typhoid fever had steadily declined since 1894—a decline attributable to the greater facility for isolation, an abundant supply of pure water, improved housing, and the

greater care taken in the supervision of those food supplies, more especially milk, which play an important part in the dissemination of this disease. The claims resulting from the enlightenment of the public cannot be met without expense, but it would be difficult to point to any example of necessary municipal expenditure in which the direct benefits, alike to the recipients and to the community, are more strongly marked. The treatment of cases of tuberculosis at the City Hospital, Fazakerley, has, in the opinion of Dr. E. W. Hope, met with great success.

St. Luke's Day Medical Service.

The annual service for the members of the medical profession in commemoration of St. Luke's Day will be held at St. Luke's Church on Sunday, Oct. 15th, at 3 P.M. The Lord Bishop of London will be the preacher. Members of the profession are invited to wear academic costume.

The Imbroglio at the Chester Infirmary.

The Mayor of Chester has, I am informed, written a letter suggesting that the matters in dispute at the infirmary be referred to a committee of three gentlemen. He suggests the names of Sir Horatio Lloyd, Judge Moss, and another to be chosen by the board of management of the infirmary. The Mayor has hopes that the adoption of his suggestion will put an end to a controversy which is harmful to the charity and which gives pain to many of its warmest supporters. He also hopes that it may result in the retention of Mr. B. C. Roberts, the late chairman, on the board of management.

The Prevalence of Diarrhœa at Crewe.

The medical officer of health of Crewe reported on Sept. 14th that during the last month 51 deaths took place in Crewe from diarrhœa. Persons of all ages had been affected, but the highest mortality had been amongst infants under 12 months, the number of deaths being 41. Of this number 33 were bottle-fed, which rendered the infants specially liable to diarrhœa in hot weather.

Sept. 18th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

St. Andrews University: 500th Anniversary.

THE celebrations of the quincentenary of St. Andrews University began on the evening of Sept. 12th with a reception by the Chancellor, Lord Balfour of Burleigh, followed by a students' torchlight procession. On the afternoon of the same day (this, however, having no official connexion with the quincentenary programme) Mr. Andrew Carnegie, who is a former Rector of St. Andrews University, was presented with his portrait in oils, painted by Mr. E. A. Walton, R.S.A. Principal Sir James Donaldson presided. There were present Lord Balfour of Burleigh, Mrs. Carnegie, Principal Sir Donald and Lady MacAlister of Glasgow, and a large number of students and others. On the 13th the proceedings commenced with a procession of students, graduates, delegates, &c., to the Church of the Holy Trinity, where the commemoration service was held. Later in the day a presentation of addresses took place in the North Hall in the presence of a great assemblage, over which the Chancellor of the University presided. After the presentation of addresses the Chancellor read the following address from the King:—

To Lord Balfour of Burleigh, Chancellor of the University.

I desire to express my regret that I cannot be present at the festival of the 500th anniversary of the foundation of the University of St. Andrews. I am deeply sensible of the national significance of the celebration of this event in the history of the oldest University in Scotland, and recognise with pride the association of my predecessors with St. Andrews.

I desire to assure the Court, Senate, graduates, and students of the University that I heartily sympathise with this auspicious event in their corporate life, and trust that it may conduce in all ways to the well-being of the University. GEORGE R. & I.

The Chancellor then welcomed the representatives from other universities who had honoured them with their presence: 100 universities and upwards of 40 other societies were represented. On the 14th Lord Rosebery, the Rector, delivered his address at half-past 10 in the North Hall, after which Sir James Donaldson was presented with an address of congratulation on his attaining 25 years of service as the Principal of the University. At the banquet in the evening Mr. A. J. Balfour delivered a splendid speech. On the 15th the proceedings were brought to a close. At St. Andrews a number of short addresses were delivered in the Volunteer Hall by distinguished guests. In the evening there was a graduates' and students' dinner in the Bell Pettigrew Museum, followed by a students' ball in the North Hall. In Dundee, to which a special train conveyed the guests, a reception was held at University College by the President, Lord Camperdown, followed by addresses in the Fleming Gymnasium by Lord Balfour of Burleigh and Lord Rosebery.

Resignation of Professor Finlay.

Professor David W. Finlay, who occupies the chair of the Practice of Medicine at Aberdeen University, has intimated that he intends to resign his professorship at the end of the present year. His resignation will come before the University Court at its next meeting, which will be held on Oct. 10th. Professor Finlay was appointed to the chair of Medicine at Aberdeen University in 1891 on the death of Professor J. W. F. Smith-Shand, and has thus held the post for 20 years. A native of Glasgow, Professor Finlay was educated in that city and in Vienna. He was for some time physician and lecturer at the Middlesex Hospital in London, and also physician to the Royal Hospital for Diseases of the Chest and to the Royal Scottish Hospital. He has also been inspector of examinations in medicine to the General Medical Council, upon which body he represented Aberdeen University. In the affairs of Aberdeen University Professor Finlay has taken a keen and practical interest. In September, 1901, he represented the University at the bi-centenary celebrations of Yale University. In 1907 he was appointed Dean of the Faculty of Medicine, while only last week he represented Aberdeen University at the Christiania University celebrations, and was one of those on whom the centenary medal was bestowed. In 1908 he was appointed one of the honorary physicians to the King in Scotland in place of the late Sir Thomas McCall Anderson, and in June of last year he became a physician-in-ordinary to King George.

Appointment of Assistant Medical Officer to Kingseat Asylum.

At a meeting of the Aberdeen City District Lunacy Board held on Sept. 12th, Dr. Ian Ogilvie of Preston was appointed assistant medical officer of Kingseat Asylum at a salary of £120 per annum. There were only three applicants in answer to the board's advertisement, the other two being ladies. Considerable discussion took place over the appointment, several of the members being of the opinion that the post should be re-advertised at an increased salary. The motion to appoint Dr. Ogilvie was eventually carried by 25 votes to 4.

The Royal Infirmary, Dundee.

The quarterly meeting of the governors of the Royal Infirmary, Dundee, was held on Sept. 15th. In submitting a report ot the work done in the institution during the last quarter the chairman said there had been 870 in-patients, as compared with 956 for last year's corresponding quarter, and 5205 out-patients, as compared with 4224. There were 383 patients in the convalescent home, compared with 375 last year, and in the sanatorium 11 adults and 33 children. The work done at the sanatorium was excellent and increasing, and the directors had decided that the laundry, which the old board of governors had had to close owing to lack of funds, would be reopened. The workshop given by an anonymous donor was in course of erection. Regarding the National Insurance Bill, the chairman said that when it was in operation there would undoubtedly be a falling off of out-patients at the infirmary and an increase of in-patients.

Outbreak of Diphtheria at Forfar.

Owing to an outbreak of diphtheria at Forfar the school board has given instructions for certain classes in the West Burgh school to be closed.

Sept. 19th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Report on the Dublin Hospitals.

THE Board of Superintendence of the Dublin Hospitals has recently issued the annual report dealing with those hospitals which are in receipt of Government grants. There are nine of these in Dublin—three general hospitals, viz., Dr. Steevens', the Meath, and the House of Industry; two lying-in hospitals, the Rotunda and the Coombe; and four

other special hospitals, the Westmorland Lock, the Cork Street Fever, the Royal Victoria Eye and Ear, and the Royal Hospital for Incurables. Two of these, the Westmorland Lock and the House of Industry, are practically maintained by Government. They receive grants respectively of £2600 and £7600 a year. The grants to the other institutions have been made at various times and without any system. Dr. Steevens' Hospital, which keeps wards for soldiers' wives and for the constabulary, gets £1300 a year. The Royal Victoria Eye and Ear receives £100. The Board of Superintendence expresses the opinion that the hospitals fulfil their objects in an economical and thorough way. The probable effect of the National Insurance Bill on voluntary hospitals is discussed as follows:—

> Hitherto the public have looked on the labouring man disabled for work as a fit object for charity. They have subscribed and left legacies to hospitals because it was known that through the wards of the hospital and the special dispensaries attached to them lay the smoothest, shortest, and most economical road to recovery. It is unlikely, should the State arrange for the care of the labouring classes when incapacitated by sickness, that the charitably inclined will continue to subscribe to the same extent. Now, there is no doubt that for the maintenance of hospitals the system of voluntary aid, supplemented by State aid, yields the best and most economical results. By it the services of men of the highest standing are put within easy reach of the poor, both in the wards and in the dispensaries. We think this system is in danger, and that if it is once allowed to collapse it may not be possible to reconstitute it. This would be a serious thing for the poor, a serious thing for the progress of science, a serious thing for the taxpayer, and for the training of gentlemen for medical service. The practice of medicine is advancing by specialisation. Each class of disease has its department in an hospital. It is not too much to say that a club doctor, responsible for the health of a large number of work-people, will, in a great majority of the cases, have to call on the hospitals or their dispensaries for help. On what terms will this be given? If the voluntary aid system is abolished it must mean a suitable remuneration for all medical service. We are of opinion that a system on such a foundation would not work as well or as economically as does the present one.

Water-supply of Irish Towns.

The scarcity of water to which reference was made in a previous letter in THE LANCET of Sept. 9th is widespread and serious. Dublin is not so badly off as some other places owing to the recently increased catchment areas and new reservoirs, but the necessity for economy is being enforced by the corporation. In Belfast the supply has been again curtailed by cutting it off between 6 o'clock at night and 9 o'clock on the following morning. The special liability of Belfast to this unfortunate shortage is due to the absence of a sufficient reservoir for the supply, which comes from the Mourne Mountains. The building of such a reservoir was part of the scheme as originally adopted, but, in the first place, the difficulties in the way of construction and the expense involved proved to be so great, and, in the second, the revenue at the disposal of the board had been so freely expended in other directions, that the Water Board felt justified in postponing the construction of the reservoir. The Act of Parliament, under which power had been taken in 1893, amongst other things, to construct a reservoir in what is called the Silent Valley, on the Kilkeel river, will expire in 1913, and as the present dry summer has demonstrated the absolute necessity for the construction of a great storage reservoir, the Water Commissioners have decided to promote a Bill next Session for an extension of the time for the construction of these works and for raising the required capital. In Derry the matter was discussed at a meeting of the corporation on Sept. 18th, when the very dangerous state of the city was pointed out. In Lisburn the principal source of water-supply to the town is exhausted and another pond is being used. The water from this source, which is regarded as impure, is also failing, and now disused wells are being opened. In the glens of Antrim, as a result of the scarcity of water, all kinds of cattle, sheep, &c., have gone down in price. No one ever remembers such a situation in Ulster. At the time of writing the drought still continues.

Dungannon Workhouse Infirmary.

As a result of the Local Government Board's report on the management of the workhouse infirmary (see THE LANCET, Sept. 16th, p. 859), the board of guardians, at their meeting on Sept. 14th, decided that the services of the head nurse be dispensed with from that day month. The motion to do this was carried by 27 votes to 12.

Death of Dr. W. Langford Symes.

Members of the profession in Ireland have learnt with much regret of the death of Dr. W. Langford Symes, who formerly practised in Dublin as a specialist in the diseases of children. In his younger days he held a dispensary appointment in county Wicklow, but desiring a wider scope for his energies he resigned his post and studied children's diseases at the Great Ormond-street Hospital, London. Returning to Ireland, he settled in Dublin, and obtained the Fellowship of the Royal College of Physicians of Ireland in 1898. For some years he edited the *Journal of the Irish Medical Association*. A few years ago his health became unsatisfactory, and he left Dublin to take up practice at Landrindod Wells. His death occurred in London on Sept. 13th. Dr. Symes was a modest but energetic man, of much real kindliness, who made many friends.

Memorial to Dr. Rutherford of Ballinasloe.

A movement is on foot to establish a memorial to Dr. William Rutherford of Ballinasloe, whose death occurred a few months ago. It is proposed to erect a monument in the town where he spent his professional life, and also to provide for the education of his youngest children. Dr. Rutherford was a cultured and capable physician, whose name was held in honour by the profession, not only of his own district, but of the entire country. The present monument on the part of the public is an unusual honour to be paid to a medical man.

Sept. 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Hygiene of Nutrition.

FOR about two years considerable uneasiness has existed throughout France over the increasing difficulty of procuring the necessaries of life at a reasonable price and of a satisfactory quality. A variety of causes has contributed to raise the price of many of the most commonly used foodstuffs. The floods of last year have diminished not only the quantity but also the quality of fruits and vegetables, and domestic animals being perforce less well nourished, the quality of their meat also has suffered, while a rise in the price of meat, milk, and eggs has taken place. This summer, with its heat, and particularly with its drought, has completed the work begun by the floods, so that now for some weeks the price of many of the most indispensable commodities has reached a considerable height on account of insufficient production. The exports remaining much about the same, the first effect of the raised prices has been felt in France itself. Sugar especially has risen in price to an entirely anomalous extent and is still on the rise, owing to the complete failure of the beet crop in many regions devoted particularly to its cultivation. This distressing state of things, moreover, has caused in towns labour troubles among the classes for whom the rise in prices is indeed a calamity, and it has become necessary on all sides to seek a remedy for this state of affairs. It is to be feared that the dearness of raw material will result in extensive adulteration, to the detriment of the general health. This will further augment the misery of the poor if the increase in the cost of provisions necessitates parsimony in providing. The labour revolts, restrained at first but constantly becoming bolder, may have the happy result of finding a way to reconcile individual interests for the public welfare.

The "Aoûtas."

By this name are designated in France certain minute red insects, which are found in abundance during very hot summers in the country, and particularly in the fields. When walking, and especially when sitting on the grass, no bite is perceived, nor is one conscious of the presence of these insects, for they are too small for observation. But at home when night comes their bites are felt and cause great distress. The insects, unlike fleas, mosquitoes, and similar creatures, are not satisfied with inflicting a single bite, they burrow under the skin and constitute a sort of timepiece, for during the day they are quiet, but towards evening they give rise to insupportable pricking, which continues during some five or six days, until, in fact, the insect dies. The bites are sometimes so massed and so painful as to simulate a true skin disease, and cases have been known in which the unfortunate victim, ignorant of what is the matter with him, has consulted medical man after medical man who gravely prescribe for some skin

disease, naturally without effect, until the patient happily falls into the hands of one who, recognising the nature of the trouble, is able quickly to relieve him.

Sept. 19th.

*** From the prominence given by our correspondent to the attacks of what are popularly termed "harvest bugs" we assume that these troublesome parasites are not as well known in France as in England, and yet some of our earliest information concerning them is of French origin. A full description of *prurigo du Rouget*, or erythema following the attacks of leptus autumnalis, was given 30 years ago in Mégnin's "Les Parasites et les Maladies Parasitaires chez l'Homme et les Animaux Domestiques." Dr. J. C. Thresh noted in our columns in the course of an article on the subject an outbreak of erythema in France described in the *Sante Publique* in 1872, where the sufferings of certain agricultural labourers led to judicial proceedings. In Brocq's "Diseases of the Skin" the action of the leptus autumnalis is also described. We refer our readers to a very full paper on the natural history and dermatitis due to these parasites, communicated by Dr. William MacLennan to the columns of THE LANCET on Dec. 16th, 1905.—ED. L.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Montreal Vital Statistics.

THE annual report of the Health Department of Montreal, recently issued by the medical officer of health, Dr. Louis Laberge, shows that the death-rate of Montreal increased slightly in 1910, while the number of births decreased. The decrease in births amounted to 0·70 per 1000 and marriages increased by 0·56 per 1000. The births numbered 16,616, or 36·45 per 1000, as compared with 37·15 of the previous year, and the marriages 4386, or 9·62 per 1000 inhabitants, as compared with 9·06 of the year before. Figures are supplied in tabulated form which tend to show that the death-rate of Montreal has not varied greatly for a number of years. In 1905 it was 22·96; in 1906, 22·98; in 1907, 22·56; in 1908, 22·95; in 1909, 22·03; and in 1910, 22·40. Neither has the birth-rate exhibited much change during the same period. In 1903 it was 36·08, and in successive years it has been: 35·90, 35·84, 37·35, 36·05, 38·43, 37·15, and in 1910, 36·45.

Contagious Diseases in Montreal in 1910.

Dr. J. E. Laberge, chief of the Contagious Diseases Department of the Montreal Board of Health, accounts for the increase in the cases of contagious diseases in 1910, which is noted in the report of the department, by stating that medical men are complying more regularly with the provincial regulations. The report for 1910 shows that the number of cases of contagious diseases was in that year 8749, as compared with 6494 for the year before, or an increase of 2255. Dr. Laberge also draws attention to the increasing number of cases of tuberculosis notified, which, in his opinion, is a matter requiring immediate notice. The cases of tuberculosis registered at the department in 1907 were 919; in 1908 the cases were 1000; in 1909 the registrations were 1114; and in 1910 these had increased to 1336.

Insanitary Conditions in Montreal.

In commenting on certain features of the above-mentioned report Dr. Louis Laberge recommends that in the future the city should not permit the opening of any street which is not supplied with a system of sewers and water mains. He further considers that tanneries, soap factories, and establishments in which green hides are cured should not be tolerated in Montreal itself, because if sanitary regulations are relaxed they become a nuisance. The construction in different parts of the city of four garbage incinerators for house refuse is recommended. Dr. Laberge suggests that further bathing facilities shall be provided. On one sin of sanitary omission nothing is said. The stranger within the gates of Montreal, especially if he comes from Europe, is greatly struck and frequently inconvenienced by the lack of public conveniences for men and women. In Montreal there are no public lavatories, with the exception of very inadequate accommodation at the railway stations. This failure on the part of the municipal authorities to provide public lavatories is not only a source of great inconvenience, but is to some extent a matter detrimental to the health of the city.

Cocaine in Montreal.

Cocaine appears to be increasingly used in Montreal. According to the annual report of the superintendent of police, 150 arrests have been made since July of this year on charges of improperly using or selling the drug.

Canadian Public Health Association.

The first annual meeting of this association will be held in Montreal on Nov. 21st to 23rd. There is to be a symposium on housing and town planning, as well as one on sewage installations.

Toronto's Slums.

Dr. Charles J. Hastings, medical officer of health of Toronto, has recently prepared an exhaustive report on Toronto's slums based upon visits of inspectors to 4693 houses. He advocates expropriating an area surrounding the city which comprises an acreage of 17,920. Of 2051 families visited in the central section of the city, 1275 families lived in four or more rooms, 348 families in three rooms, 227 families in two rooms, 139 families in one room, 61 families in basements, and 1 family in a cellar. 108 of these houses were pronounced unfit for human habitation. There are 92 tenement houses in Toronto.

A Hospital for Inebriates.

The Ontario Society for the Reformation of Inebriates aims to promote the reformation of indigent inebriates in Ontario by making use of the public hospitals of the province and by combining therewith the Massachusetts probation system. In Toronto a medical officer and a probation officer attend the police court, and offer medical treatment and help to the inebriate. Medical treatment is given either at the home of the prisoner or in the office of the medical man. But the society is hampered in its work by the need for a special hospital entirely devoted to the treatment of inebriates. The Ontario Government has this project under consideration, and some such institution may be looked for in the immediate future.

The Laurentian Sanatorium.

A few weeks ago the new Laurentian Sanatorium at Ste. Agathe des Monts, province of Quebec, was officially opened. Situated about 100 miles from Montreal, overlooking one of the beautiful valleys of the Laurentians, where the climate is comparable to that of the famous Saranac Lake institution, this sanatorium commands one of the finest situations in all Canada. The building and equipment enhance the value of the situation. The building has accommodation for 50 patients and is so constructed that wings can be added at any time. Amongst those who attended the opening ceremonies were Dr. Baldwin and Dr. Kinghorn of Saranac Lake, Dr. Adami and Dr. Lafleur of Montreal, and Dr. Otis of Boston. Under the auspices of the Laurentian Society, which inaugurated this work, Ste. Agathe des Monts will be a centre in the province of Quebec for the scientific treatment and study of incipient tuberculosis. In Canada, so far, most of the practical work in fighting tuberculosis has been carried on by private philanthropy. Governments should well consider a remark of Dr. Kinghorn in his address: "Any patient, taken in time, is practically sure of being cured."

Inspection of School Children in Ontario.

The Ontario Medical Council passed the following resolution with regard to the inspection of school children at its recent annual meeting:—

That the Council, in the interests of school children, respectfully recommend to the Minister of Education the advisability of taking a physical census of the school children, with the view of comparing the health and physical condition of children in urban and rural districts; and in the meantime further recommend the training, as in England, of the students in the model schools, normal schools, and faculties of education in such a knowledge of school hygiene as will enable them to recognise common defects and diseases of children.

Fire at the Hamilton Hospital for the Insane.

The Hospital for the Insane at Hamilton, Ontario, was partially destroyed by fire on August 1st. Eight of the inmates perished in the flames. The hospital had a capacity of 1220, and there were in residence on Oct. 1st last 1223 patients.

Sept. 11th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

The Failure of the Monsoon.

ONLY those who have been in a famine-stricken area can realise what the failure of the monsoon means. The "trade winds" may be regarded as divided into a western and an eastern half so far as India is concerned. The eastern half has not failed, but the western wave may now be said to have failed more or less completely, as it is now the third week of August and there has been very little rain in the western areas of India. The Central and United Provinces and the Punjab are chiefly affected. There must be famine now in some areas, though, of course, we are more prepared for this, and such irrigation works as there are have done much to lessen it. The heat has been continuous and intense. In some parts of the Punjab the *mean* for the last three months has been over 106° F. in the shade. The humidity, of course, has been only about 52. The chances are against malaria. The cause of the monsoon failure is most probably related to the very late, heavy fall of snow in the Western Himalayas, which did not occur in the Eastern Himalayas. The cold current of air has prevented the trade winds taking their usual course, and so we find the lower West of India having a large amount of rain.

Malaria in Bombay.

Dr. C. A. Bentley's report on malaria in Bombay and the Government resolution thereon, which were referred to in THE LANCET of Sept. 2nd, p. 732, form the chief subject of medical interest in Bombay. The report showed an appalling degree of malaria, and Dr. Bentley traced this to the wells in and about houses. The report showed a large percentage of infection among Parsees. It has now been discussed by the corporation. As usual with such reports, Indian medical practitioners of the corporation were not behind in giving vent to criticisms. Much of this criticism did not reflect on the speakers. Dr. Sukhia agreed with Dr. Bentley that fever was rampant among the Parsees, but he did not agree with the figures for the incidence of spleen index. He thought that Dr. Bentley had applied himself to his work with a preconceived idea that the Parsees suffered from malaria on account of the wells in their houses. In his opinion the works at the docks, &c., were the chief causes of the outbreak in 1908 and in previous years. Mr. Mistry thought that the report was intended to whitewash the report of the special commission appointed by the Government of India at Mian Mir. Sir Balchandra Krishna thought malaria chiefly due to works carried out by the Part Trust and railways, and that they should be called on to contribute substantially to the cost of measures decided upon. Dr. Dadachanji disagreed with Dr. Bentley's charges against the wells as the chief cause. Mr. D. P. Vacha said some hard things. He objected to any statutory powers being given to any inspector to enter houses. The proposition before the corporation, to appoint a committee to consider the action to be taken to stamp out the scourge, was carried.

Three Years' Progress in Bengal.

The triennial reports of the year are now published. The Inspector-General of Civil Hospitals in Bengal shows how malaria is being fought in that province. A committee was established, investigations were carried out, and quinine was sold at 10 grains to the pice. In 1910, 1,570,666 packets and 1,181,140 tablets were sold. Sub-assistant surgeons were deputed to give medical relief in the worst areas. Instruction on the cause and treatment of malaria is about to be tried in schools. During the triennial period 24 new dispensaries were opened under Government supervision. The Inspector-General points out that the medical requirements of the province have in no sense as yet been adequately met, and in some districts—e.g., Muzaffarpur with one dispensary for 227,566 persons—the population is out of all proportion to each dispensary available for their use. The reason for this deficiency is lack of funds. Colonel Harris pays a tribute to medical missions, but these alone do not suffice to fill the gap which exists.

Eastern Bengal and Assam.

The sanitary report for this province for 1910 shows a birth-rate of 37·96 per 1000 and a death-rate of 33·71 per 1000. Dr. Bentley has been appointed as a Deputy Sanitary Commissioner for five years, and has been given a special medical staff to carry out measures against malaria. The operations at Dinajpur and Jalpaiguri were not successful.

Professorships at Lucknow.

The new Medical College at Lucknow is to have five whole-time professors, of whom four will be officers of the Indian Medical Service. Of these, the professor of bacteriology and pathology will, in addition, be the chief surgeon. He will also carry out all post-mortem examinations. There are to be two lectureships—viz., in forensic medicine and materia medica, and these are to be given to military assistant surgeons. These do not possess *registrable* qualifications. The General Medical Council may take note of this, and examining bodies in England will have to awake to the fact that certain class certificates given in India should not be accepted for degrees in Britain.

August 26th.

NOTES FROM CHINA.

(FROM OUR OWN CORRESPONDENT.)

Hong-Kong Medical and Sanitary Report for 1910.

THIS report. which has just been issued, compares favourably with those of former years and reflects credit on the public health authorities, who, in the midst of a continually changing and overcrowded population, have to cope with more difficulties than occur in almost any other British colony. Last year the rainfall was 70 inches, considerably below the average of the past 20 years. The total population of the colony is 350,975, of whom 330,169 are Chinese and 11,532 are Europeans and Americans. Among Chinese the death-rate was 22·50 per 1000, and among non-Chinese it was 10·04 per 1000, which contrasts very favourably with that of the United Kingdom, though it must be borne in mind that over half the population is between the ages of 20 and 45. With reference to the statistics I have given in previous notes of the high infant mortality in Peking, it is interesting to see that among the Chinese the known deaths of infants numbered 2495, while only 1253 births were registered. This surplus is explained by the fact that numbers of children are being brought into the island from the mainland, but the figures are significant enough to show the huge wastage of child life in the Far East.

Respiratory diseases.—Phthisis alone accounts for 780 deaths, of which 765 were Chinese. Pneumonia caused 1165 deaths, of which 1153 were Chinese. The deaths from phthisis among Chinese were 10·3 per cent. of the total deaths in that community. Considerable efforts have been made to put a stop to the inveterate habit of spitting in public buildings, dwellings, and on footpaths, wharves, &c. At the instance of the Government an anti-spitting league was formed by leading Chinese, which has been active in its endeavours to check this obnoxious practice.

Nervous diseases.—There were 257 deaths of infants less than one year old from tetanus, trismus, and convulsions.

Malarial fever.—The total number of deaths was 591, of which nine only were those of non-Chinese. Anti-malarial measures have received considerable attention from active sanitary staffs, over $30,600 having been spent in the year on drainage and on oiling mosquito-breeding haunts. The incidence of malaria was somewhat higher than in previous years, and one of the explanations given for this is the greater uniformity of the rainfall during 1910, when there was an almost daily succession of small showers during the rainy season, sufficient to keep the breeding-pools supplied with water, and an absence of heavy rain storms, which have the effect of scouring out the many rock pools that constitute the greatest difficulty in regard to anti-malarial measures in the colony.

Beri-beri.—566 deaths occurred, and the cause of this disease is attributed in Hong-Kong to the eating of white or polished rice—a different view to that of Shanghai, where the public health authorities are inclined to lay the cause at the door of body vermin.

Plague.—The incidence of plague was very light, only 25 cases, with 23 deaths, being recorded, of which four were imported. Active rat catching and collection were carried on throughout the year.

Typhoid fever.—There were 67 cases of this disease, with a case-mortality among Europeans of 12 per cent. In most of the cases the infection was probably contracted by eating salads of raw vegetables grown in Chinese market gardens, where it is customary to water and manure the plants with diluted urine and night soil.

In the Tungwah Hospital, where patients on admission can elect to be treated by European or Chinese methods, there is annually a big balance of success in favour of western medicine. In spite of that fact, many Chinese persist in preferring their own system, as shown by the greater number of admissions to the native side of the hospital. During 1910 there were 1699 who asked for European treatment, of whom 199 died, while of 2062 who underwent Chinese treatment 747 died. A large number of post-mortem examinations were carried out, and the statistics of the bacteriological laboratory show that it is in a high state of efficiency.

Abscess for Ten Years following Abortion.

A remarkable case is reported by Dr. A. C. Hutcheson of Kashing, Chekiang, of a Chinese woman who complained of acute abdominal pain and had more or less constant vaginal discharge. A distinct mass, exquisitely tender, was found in the lower right quadrant of the abdomen, and on vaginal examination a hard body was felt projecting from the cervix about a quarter of an inch. When this was pulled out it was found to be a Chinese chopstick eight inches long, with sharpened end. Its withdrawal was followed by the discharge of bloody pus of the foulest odour. The patient was absolutely ignorant of the presence of a foreign body in her uterus. Dr. Hutcheson then learnt that ten years before she had called in a Chinese midwife to perform an abortion, having had three children in rapid succession and desiring a rest from her labours. During all this time she had suffered from severe attacks of abdominal pain, sometimes with, sometimes without, fever, but almost constantly with foul bloody discharge. During the attacks she was confined to bed. She was able to attend to her work. A laparotomy was performed, and on opening the peritoneum fluid blackish pus gushed out. Tubes were introduced through the abdominal wound and thorough vaginal drainage was established. Some weeks later the patient left the hospital cured. Ten years seems a long period of time and must almost be a record for septic inflammation following perforation of the uterus. It also seems strange that in ten years nature did not establish an effective barrier to the absorption from the abscess cavity, but allowed the woman to suffer from the toxins developed all that time. The chopstick no doubt acted as a drain whenever the tension became too great in the abscess cavity, thus accounting for the intervals of freedom from severe pain. Dr. W. H. Venable of Kashing last year removed a chopstick a foot long from a patient's vagina. This one had been in 13 months. It was pushed through the posterior fornix up into the posterior part of the pelvis.

Peking, August 15th.

Obituary.

JAMES REID, F.R.C.S. ENG., L.S.A.

BY the death of Mr. James Reid, which took place on Sept. 12th, Canterbury has lost a citizen to whom it owes much, for the improved sanitary condition of that city is due in a large measure to his work. He was born in 1821 at Hampstead, and after serving as apprentice to a medical practitioner, he studied at St. Bartholomew's Hospital and was one of the first to live in the residential college which was opened with Sir James Paget as Warden. In 1843 he qualified by taking the Membership of the Royal College of Surgeons of England, and started in a joint practice at Dover. In the following year he became a Licentiate of the Society of Apothecaries of London, and in 1876 was elected a Fellow of the Royal College of Surgeons. In 1846 he removed to Canterbury, where he was soon actively occupied in all that concerned the medical interests of the city. He rendered invaluable services to the Kent and Canterbury Hospital, to which he was senior surgeon for many years and afterwards consulting surgeon. He was formerly surgeon to H.M. prison at Canterbury. Mr. Reid was one of the promoters of the East Kent Natural History Society, and for many years he was its honorary librarian. The Canterbury Nurses' Institute also owed much to him, as joint founder and honarary secretary and treasurer.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. G. Jochmann of Breslau has been recognised as *privat-docent* of Medicine.—*Bonn:* Dr. C. Menge of Heidelberg has been appointed to the chair of Midwifery and Gynæcology in succession to Dr. H. Fritsch, resigned.—*Breslau:* Dr. J. Pohl of Prague has been appointed to the chair of Pharmacology in succession to Dr. W. Filehne, resigned.—*Florence:* Dr. E. Marri has been recognised as *privat-docent* of Ophthalmology.

Dr. T. B. Hyslop will deliver the first Hunterian lecture before the Hunterian Society on Oct. 11th at 9 P.M. He has chosen as his subject, "Intracranial Murmurs and their Relation to Tinnitus Aurium."

Mr. Alexander Gray, M.B., C.M. Glasg., a well-known practitioner in Bradford, died on Sept. 15th. While present at an operation at the Bradford Royal Infirmary he was taken suddenly ill and expired almost immediately.

THE Lettsomian lectures of the Medical Society of London will be delivered at the rooms of the society, 11, Chandos-street, Cavendish-square, W., on Feb. 5th and 19th, and March 4th, 1912, by Dr. Archibald E. Garrod, F.R.S., who has taken as his subject Glycosuria.

LITERARY INTELLIGENCE.—With the view of making the eleventh edition of "Quain's Anatomy" more easily accessible to students Messrs. Longmans, Green, and Co. are re-issuing the volumes already published at lower prices. Vol. I., Part 2, Histology, by Professor Schäfer, is expected to appear in the autumn.

THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—The opening of the seventieth session of the School of Pharmacy will take place at 17, Bloomsbury-square, London, W.C., on Wednesday afternoon, Oct. 4th, at 3 o'clock, when the presentation of the Hanbury gold medal will be made by the President, and the inaugural sessional address will be delivered by Dr. J. Macdonald Brown.

REMEDIES FOR BABY-FARMING EVILS.—Miss F. Zanetti, the inspector in the township of South Manchester, read at Berlin a paper on the Protection of Illegitimate Children Nursed for Hire, at the Third International Congress for the Study and Prevention of Infantile Mortality. The following were among the points that she made. The protection afforded by the State to infants nursed for hire should not be confined to illegitimate children; as they, however, form probably about nine-tenths of the total number it may be assumed that the recently secured legislation in England is intended chiefly for the benefit of those unfortunates. If boards of guardians availed themselves of their full powers the condition of children nursed for hire would be greatly improved and baby-farming of the worst type suppressed, provided especially some amendment was obtained to make registration compulsory when children are received for reward, without specifying the time (at present 48 hours) during which they may be kept without notification. "Middlemen" between persons anxious to dispose of children and others wishful to adopt infants with whom a substantial premium is paid require suppression. It would appear that there are a number of people who make money by adopting infants for sums of money, passing on such infants within the 48 hours during which a child may be nursed without the sanction of the authorities, at the same time retaining a portion of the premium received. The adoption of the amendment regarding registration above mentioned would check the traffic and at the same time provide supervision for the large number of infants nursed by day only, who are frequently left in charge of very old and incapable nurses during the hours when the mothers are at work.

MISSIONARY EXHIBITION.—It is proposed by the Society for the Propagation of the Gospel to hold a large Missionary Exhibition at the Church House, Westminster, during June, 1912. At this exhibition one of the special features will be the Medical Missions Department. A sub-committee has been formed, calling itself the "Mission Hospital Committee," including a number of the leading medical men in London. The chairman is Sir Francis Champneys. Mr. James Anderson Robertson, secretary of the Medical Missions Department, S.P.G., and interim secretary of the Mission Hospital Commitee, writes from 15, Tufton-street, Westminster, S.W., to appeal to medical men, missionaries, and others throughout the country, who are in possession of interesting medical curios of other lands, to give them on loan during the time the exhibition is being held. The greatest care will be taken of them, and they will be returned to their respective owners immediately the exhibition is over.

THE ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH.—The election is announced of Dr. Theodore C. Janeway to fill the vacancy on the board of scientific directors of this institute caused by the death of Dr. C. A. Herter. The board has entire control of the scientific work done by the institute. Its other members are Dr. William H. Welch of Baltimore, Dr. Theobald Smith of Boston, and Dr. L. Emmett Holt, Dr. Herman H Biggs, Dr. T. Mitchell Prudden, and Dr. Simon Flexner, all of New York. Dr. Janeway is a graduate of the Sheffield Scientific School of Yale University, and took his M.D. at the College of Physicians and Surgeons (Columbia University) in 1895. Since 1909 he has been Band Professor of the Practice of Medicine at the College of Physicians and Surgeons, and is on the medical staff of the Presbyterian Hospital, New York. He is also secretary and treasurer of the Russell Sage Institute of Pathology. Dr. Janeway has done important work on the subjects of blood pressure, diseases of metabolism, and cardio-vascular changes in nephritis.

LIFE ON THE OXO CATTLE RANCHES.—A very interesting series of kinematograph pictures illustrating farm life in the Argentine was shown to a selected audience of journalists on Sept. 18th, at the Oxo factory of the Lemco and Oxo Company in Park-street, Southwark Bridge, London, S.E. The incidents in the daily life on the Oxo cattle ranches were admirably portrayed and most realistically produced. The demonstration served to show the magnitude of the company's industries, and the care which is taken to provide pure and standard products. Mr. Charles F. Gunther, the chairman of the company, gave some interesting and remarkable figures in regard to the enormous herds of cattle belonging to the company and some particulars also showing how free from disease these animals were which spent their life entirely in the open air. He further quoted figures bearing upon the food value of grass and the quantities of grass and water daily consumed by 350,000 head of cattle. Some calculations of this kind were also made by our Special Commissioner some years ago on the occasion of his visit to the Liebig cattle farms in Argentina.

THE TREATMENT OF TUBERCULOUS JOINTS: A PUBLIC SPIRITED EXPERIMENT AT BRIGHTON.—The experiment at Brighton of treating patients suffering from tuberculosis of bones and joints at the sanatorium sanctioned by the Brighton town council in the early part of last year at the request of the medical officer of health, Dr. Duncan Forbes, is evidently meeting with success. The sanitary committee is pleased with the results, inasmuch as it has just sanctioned the experiment being continued for a further period of 12 months. Dr. Duncan Forbes in his report to the committee says: "Since March 8th last 2 cases of hip disease have been discharged cured and without deformity while 1 case of knee-joint disease was discharged for operation as it showed no material improvement. There are now 9 tuberculous joint cases in the sanatorium, 4 of spinal disease and 5 of hip-joint disease. Of these cases, 1 of hip and 1 of spinal disease are cured and will be discharged in a few days. Of the remaining 7 cases, 3 have been in hospital for over a year and still require some months' treatment, and 4 have been in hospital for a shorter period and are progressing satisfactorily." The estimated cost of the experiment for 12 months is put at £320.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ACOMB, L., M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Anæsthetist to the Newport County Hospital.

HUNTER, C. S., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Carnoustie District of the county of Forfar.

MARSHALL, C. B., M.B., Ch.B., D.P.H. Vict., has been appointed Assistant House Surgeon at the Ancoats Hospital, Manchester.

McDONALD, N., M.B., Ch.B. Vict., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Senior House Surgeon at the Ancoats Hospital, Manchester.

MORETON, R., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Overton District of the county of Flint.

MOSS, LOVEL, M.B., Ch.B Vict., has been appointed Assistant House Surgeon at the Warrington Infirmary.

TITCOMBE, R. H., M.D., Ch.B., D.P.H. Vict., has been appointed House Physician at the Ancoats Hospital, Manchester.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRKENHEAD BOROUGH HOSPITAL.—Senior Resident House Surgeon. Salary £100 per annum.

BIRMINGHAM, UNIVERSITY OF.—Lecturer in Physiological Department. Salary £150 per annum.

BODMIN, CORNWALL COUNTY ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £140 per annum, with rooms, rations, laundry, and attendance.

BOLINGBROKE HOSPITAL, Wandsworth Common, S.W.—Two House Surgeons for six months. Salary at rate of £75 per annum, with board and residence.

BRADFORD ROYAL INFIRMARY.—House Physician, unmarried, for six months. Salary at rate of £100 per annum, with board, residence, and washing.

BRISTOL ROYAL INFIRMARY.—House Surgeon. Salary £100 per annum, with apartments, board, and laundry.

BRITISH LYING-IN HOSPITAL, Endell-street, W.C.—Physician.

BURY INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, residence, and laundry.

CANCER HOSPITAL, Fulham-road, London, S.W.—House Surgeon for six months. Salary £70 per annum.

CAPETOWN, SOMERSET HOSPITAL.—Two Assistant Medical Officers. Salary £200 per annum, with rations and quarters.

CHARTHAM, NEAR CANTERBURY, KENT COUNTY ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £192 per annum, with quarters, washing, &c.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Clinical Assistant for three months.

COLCHESTER, ESSEX COUNTY HOSPITAL.—House Surgeon. Salary £80 per annum, with board, washing, and residence.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Junior House Surgeon. Salary £40 per annum, with rooms, board washing, and attendance.

DERBY BOROUGH ASYLUM.—Assistant Medical Officer, unmarried. Salary £140 per annum, with apartments, board, and washing.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Assistant House Surgeon, unmarried, for six months. Salary at rate of £75 per annum, with board, apartments, laundry, &c.

DREADNOUGHT HOSPITAL, Greenwich.—Two House Physicians and Two House Surgeons, all for six months. Salary in each case £50 per annum, with board, residence, and washing. Also Honorary Anæsthetist.

DUDLEY, GUEST HOSPITAL.—Assistant House Surgeon for six months. Salary £75 per annum, with residence, board, and washing

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Second Medical Officer for six months. Salary at rate of £40 per annum, with luncheon and tea provided.

ENNISKILLEN, FERMANAGH COUNTY HOSPITAL.—House Surgeon. Salary £72 per annum.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, London, S.E.—Ten qualified Clinical Assistants.

EXETER, ROYAL DEVON AND EXETER HOSPITAL.—House Physician and Assistant House Surgeon for six months. Salary at rate of £60 per annum, with board, apartments, and washing.

GRIMSBY AND DISTRICT HOSPITAL.—Locum Tenens for two months. Salary £4 4s. per week, with board, lodging, washing, &c.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—Assistant House Surgeon. Salary £75 per annum, with board, residence, and laundry.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.—Medical Officer. Salary 25 guineas per annum.

HARTSHILL, STOKE-ON-TRENT, NORTH STAFFORDSHIRE INFIRMARY.—House Surgeon. Salary £100 per annum, with apartments, board, and washing.

HASTINGS, EAST SUSSEX HOSPITAL.—Assistant House Surgeon. Salary at rate of £50 per annum, with residence, board, and washing.

INVERNESS DISTRICT ASYLUM.—Junior Assistant Physician. Salary £120 per annum, with board, lodging, and laundry.

KING'S COLLEGE HOSPITAL, London.—Sambrooke Medical Registrar.

LEAMINGTON SPA, WARNEFORD, LEAMINGTON, AND SOUTH WARWICKSHIRE GENERAL HOSPITAL.—House Surgeon. Salary £100 per annum, with residence, board, and laundry.

LEEDS GENERAL INFIRMARY.—Resident Medical Officer. Salary £150 per annum, with board, residence, and washing.

LEWES VICTORIA HOSPITAL AND DISPENSARY.—Resident Medical Officer. Salary £120 per annum, with apartments, board, washing, attendance, &c.

LINCOLN COUNTY HOSPITAL.—Junior House Surgeon, unmarried, for six months. Salary at rate of £75 per annum, with board, residence, and washing.

LISTER INSTITUTE OF PREVENTIVE MEDICINE.—Assistant Bacteriologist. Salary £250 per annum.

LIVERPOOL EYE AND EAR INFIRMARY, Myrtle-street.—Honorary Assistant Surgeon.

LIVERPOOL WORKHOUSE HOSPITAL, Brownlow Hill.—Two Resident Assistant Medical Officers. Salaries £120 and £100 per annum respectively, with apartments, &c.

LOUGHBOROUGH AND DISTRICT GENERAL HOSPITAL AND DISPENSARY.—Resident House Surgeon. Salary £120 per annum, with rooms, attendance, board, and washing.

MANCHESTER ROYAL INFIRMARY.—Surgical Registrar. Salary £70 per annum.

MANCHESTER WORKHOUSE HOSPITALS, Withington.—Third Assistant Resident Medical Officer. Salary £100 per annum, with rations, apartments, and attendance.

MELROSE, ROXBURGH DISTRICT ASYLUM.—Assistant Medical Officer. Salary £160 per annum, with board, lodging, and washing.

NEWCASTLE-ON-TYNE DISPENSARY.—Visiting Medical Assistant. Salary £160 per annum.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—House Physician and House Surgeon for six months. Salary in each case at rate of £52 10s. per annum, with board and residence.

POPLAR HOSPITAL FOR ACCIDENTS, Poplar, E.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board and residence.

PRESTON COUNTY ASYLUM, Whittingham.—Assistant Medical Officer, unmarried. Salary £150 per annum, with board, apartments, and washing.

PRESTWICH COUNTY ASYLUM, near Manchester.—Pathologist and Assistant Medical Officer. Salary £200 per annum, with board, apartments, attendance, and washing.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Resident Medical Officer for four months. Salary at rate of £60 per annum, with board, residence, and washing.

REDHILL, EARLSWOOD ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, with board, residence, and washing.

ROYAL EAR HOSPITAL, Soho.—House Surgeon. Salary £40 per annum.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—Resident House Surgeon, unmarried, for six months. Salary £100 per annum, with board, residence, and washing.

ROYAL SUSSEX COUNTY HOSPITAL.—Two Assistant House Surgeons, unmarried. Salary in each case £80 per annum, with board, apartments, and laundry.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.—Honorary Dental Surgeon.

ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Honorary Gynæcologist.

SALFORD ROYAL HOSPITAL.—Casualty House Surgeon for six months. Salary at rate of £50 per annum, with board and residence.

SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone-road, N.W.—Resident House Surgeon. Salary £80 per annum, with board and residence.

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—House Physician. Salary £100 per annum, with rooms, board, and washing.

SOUTHWARK UNION INFIRMARY, East Dulwich Grove, S.E.—Assistant Medical Officer. Salary £120 per annum, with board, lodging, and washing.

STOCKPORT INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, washing, and residence.

THROAT HOSPITAL Golden-square, W.—Resident House Surgeon. Salary £75 per annum, with board, residence, and laundry. Also Honorary Assistant Registrar.

WALSALL AND DISTRICT HOSPITAL.—House Physician and Casualty Officer. Salary £80 per annum, with board, residence, and laundry.

WIGAN, ROYAL ALBERT EDWARD INFIRMARY.—Junior House Surgeon. Salary £100 per annum, with rations, washing, and apartments.

WEST LONDON HOSPITAL AND POST-GRADUATE COLLEGE, Hammersmith-road, W.—Clinical Assistants. Also Three Non-resident Assistant House Surgeons, each for three months.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon for six months. Salary £80 per annum, with board, rooms, and laundry.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Dungannon, in the county of Tyrone.

Births, Marriages, and Deaths.

BIRTHS.

DAVIES.—On Sept. 10th, the wife of Langford George Davies, M.A., M.B., B.C. Cantab., of Broad Clyst, Devon, of a son.

MARRIAGES.

BEAUMONT—KING.—On Sept. 16th, at All Saints' Church, Weston-super-Mare, Noel Charles Beaumont, M.R.C.S., L.R.C.P., to Ethel Mary, eldest daughter of Mr. J. J. H. King, of Gordon-road, Weston-super-Mare.

DEATHS.

DILLON.—On Sept. 14th, Thomas Augustine Dillon, F.R.C.S. Irel., L.R.C.P., Assistant Medical Superintendent to the Croydon Infirmary, aged 33 years.

GROGONO.—On Sept. 11th, at Witham Lodge, Romford-road, Stratford, Walter Atkins Grogone, F.R.C.S., aged 62 years.

Notes, Short Comments, and Answers to Correspondents.

AN EPIDEMIC OF SUPERSTITION.

THERE are worse visitations than those of Asiatic cholera or the pestis bubonica, visitations which, provoked by ignorance, superstition, and panic, play into the hands of disease itself by thwarting the measures adopted to combat it—nay, turning with savage vendetta against the sanitary officer and the practitioner, and forcing him, in self-defence, to resort to the lethal weapon—the *dernier ressort* of the individual threatened with loss of life by the "murderer with intent" or the man-eating beast of prey. Once and again the duty-doing medical man in Italy has had to use the revolver to protect himself against the individual or the mob who, under the delusion that he was causing the disease he was in the act of curing, have attempted to do him to death! And this in the twentieth century and in such centres of Italian civilisation as the Roman or the Tuscan Province! From Pisa I learn (writes an Italian correspondent) that in the neighbourhood of the marble quarries of Carrara a local practitioner, called to the bedside of a patient who showed symptoms of cholera, found the conditions such that an injection of caffeine was indicated. He was proceeding to act accordingly when the patient's brother threatened to kill him if he attempted the operation. This menace notwithstanding, the practitioner, seeing his patient in imminent danger of collapse, seized the opportunity of their being alone together and injected the stimulant. But its restorative action proved only temporary, and the patient, in spite of every care, ultimately expired. The brother, on learning that the injection had been practised, made straight for the doctor and shot him dead with one discharge from his revolver. The incident became immediately known throughout the neighbourhood, and the doctor's brother sought out the assassin, and with six shots from his revolver killed him in turn. To such tragedies has the "Third Italy" accustomed us during the epidemic of cholera now happily on the wane. Nothing more lamentable occurred in the successive visitations of the disease in the "sixties," the "seventies," and the "eighties" of last century—so little impression has the Government's system of education made on the populace under its control. In the southern provinces the recent outbreak of the disease provoked the peasantry to excesses described by a local resident as only to be paralleled by the reign of terror during the French revolution—storming the lazzarettos, driving away the *personnel* with threats of assassination, and dragging the patients out of bed when manifestly on the way to recovery or even when convalescent. But such acts as that above reported from Carrara were supposed to be impossible in Tuscany. In Leghorn the peasants refused to comply with the sanitary prescriptions or regulations; they ate whatever they chose; they resisted with violence all attempts to take them to the lazzaretto; and, shutting themselves up in their houses, kept the authorities in the dark as to the cholera-stricken among them. At last the said authorities broke into the houses by force—only to find in one tenement 26 dead bodies, some concealed in a wardrobe, and a child's corpse in a chest of drawers. The mortality is thus difficult to estimate; while of the cases duly reported to the sanitary office it is known that about 100 proved fatal per diem. The disease, as already stated in THE LANCET, affected the seaboard mainly, such cases as occurred inland being few and seldom fatal. With the return of the cooler weather the visitation is everywhere on the wane, and in the opinion of educated and enlightened Italy the next duty of the Government must be, not only to place the hygiene of the harbour towns and the great centres on a more satisfactory footing, but to urge on the provisions (effective enough on paper) for public instruction, and redeem Italy from the more than mediæval ignorance and superstition into which she has been allowed to lapse.

APPENDICITIS AND METAL DISH-CLOTHS.

A "Bluestocking-Housewife" writes:—"I read lately of an 'epidemic' of appendicitis in an institution for boys, which led to searching but fruitless endeavours to discover its origin. I understand also that doctors generally are seeking some domestic cause for the present prevalence of appendicitis. I would offer to their consideration the tinsel dish-cloths now so commonly used to scour the inside of saucepans and other utensils in which food is cooked. Of course, no particles of the scouring substance, be it monkey soap, sand, or metal dish-cloth, are supposed to remain in the saucepan. In theory all are swept out in the subsequent rinsing. In practice I am confident that, with the most thorough servant, such rinsing is neither forcible enough nor lengthy enough to dislodge them all, minute particles will be left in various crevices, such as the groove where bottom and sides of the saucepan meet. But the boiling of the next lot of food in the pot will set up far more searching and prolonged fluid currents; these will effectually sweep

out the tiny sharp bits of metal from their resting places, to mingle them with the food. Surely such metallic particles must be a grave source of danger to the delicate internal membranes of the body? I enclose a specimen of this little cloth."

The dish-cloth forwarded to us proved to be a network of fibre and copper filaments. The device serves as an excellent scourer, but whether it parts with its copper during the process we have not been able to decide. The point raised by our correspondent is of interest, and if there is anything at all in the mechanical theory of the origin of appendicitis the use of such a cloth would be open to suspicion. The scourer is new to us, and we are probably safe in saying that appendicitis was prevalent before this novelty was pressed into the service of cleaning cooking utensils. Copper is, of course, likely to prove an irritant, but we are not aware that the metal has been found in the appendix vermiformis.

THE CROSS-CHANNEL SWIM.

To the Editor of THE LANCET.

SIR,—It having been stated and advertised in the public press that during my Channel swim I partook of various forms of nourishment, I think it only fair to state publicly that my only food consisted of Swiss milk chocolate and a few grapes, and the leg of a chicken.

I am, Sir, yours faithfully,

T. W. BURGESS.

Lorne Cottage, Dover-street, Walmer, Sept. 20th, 1911.

A SAFETY HAT-PIN.

Mrs. Dunn, of Woodfield, Uppingham, Rutland, has invented a new form of safety hat-pin. This consists of two pins used as a pair, and so arranged that the head of one pin protects the point of the other pin, and *vice versâ*. Owing to the fact that the pins are equal in length, it would be difficult to manipulate such an arrangement if the heads were fixed. To overcome this difficulty one or each of the pins forming a pair is provided with a head which is hinged in relation to the pin proper. One of the pins having been inserted in the hat and hair of the wearer in the usual manner, the second pin is then inserted from the opposite direction so that its point enters the head of the first pin, after which the head of the pin last inserted may be moved so that it is thrust on to the point of the first pin. The pin-heads, which are hollow, are filled with cork covered by wire

gauze, which holds the point of the pin firmly. "It is clear, therefore," says the inventor, "that when in position the points of the pins are adequately and thoroughly protected, and further, that they are not likely to be accidentally withdrawn." The pins may be made of any length, and the heads of any suitable material ornamented in any manner desired. The inventor claims that it is only necessary to wear one pair of these pins with a hat, as any ordinary pin may be used if more than two are required, the point of this ordinary pin being passed into the head of one of the special pins. The real dangers to the community from the vicious spear-heads which radiate from the hat of the modern lady need no expatiation. Serious accidents have been chronicled, and many persons must have felt, when riding in omnibuses, for example, that a sudden jolt of the vehicle might cost them the loss of eyesight. The new fastener removes a public peril, and appears to us, while doing so, to leave the wearer in as good a position with regard to her headgear as if she were wearing the usual naked arsenal. The fact that a third pin can be introduced practically at any angle to either of the other two will give the security that two or more parallel pins could not give.

Senex.—The appointments are generally badly paid, and those that are not are difficult to obtain. The candidate should apply to the Pharmaceutical Society, 17, Bloomsbury-square, London, W.C., having just reached the necessary age.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for September and October, 1911:—

April–October.—Rome Exhibition (United Italy's Jubilee).
,, 29th–Oct. 26th (Turin).—International Exhibition.
May 3rd–Oct. 31st (Glasgow).—Scottish Exhibition.
,, 6th–Oct. 31st (Dresden).—International Hygiene Exhibition (British Section opens June 14th).
May 12th–Oct. 31st (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
May 18th–October 31st (London, Shepherd's Bush).—Coronation Exhibition.
,, 19th–Oct. 31st (London).—Earl's Court Exhibition.
Sept. 16th–23rd (London, Agricultural Hall).—Nineteenth Annual Grocery Exhibition and Market.
,, 18th–23rd (Sydney).—Australasian Medical Congress.
,, 18th–23rd (Paris).—International Conference of Genetics.
,, 23rd–Oct. 21st (London, Olympia).—Electrical Exhibition.
,, 24th–30th (Karlsruhe).—Eighty-third Meeting of German Physicists and Physicians.
,, 25th–26th (Munich).—Meeting of the International League for Medical Psychology and Psychotherapy.
,, 26th–28th (Louisville, Ky.).—American Association of Obstetricians and Gynecologists.
,, 26th–30th (Brussels).—Third Congress of the International Society of Surgery and Exhibition of Fractures.
,, 28th and 29th (Manchester).—Conference of British Hospitals Association.
,, 28th–30th (Dresden).—International Congress for the Protection of Mothers and Sexual Reform.
,, 29th (Edinburgh).—Association of Veterinary Officers of Health. Annual Meeting.
,, 30th (Bruges).—Sixth Belgian Congress of Neurology and Psychiatry.
September (Genoa).—International Exhibition of Marine Hygiene.
,, (Turin).—Congress of the Association of Italian Railway Physicians.
September–November (Antwerp).—International Exhibition of Alimentation, Brewing, Wines, and Liqueurs.
Oct. 1st–4th (Liége).—Second Congress of Alimentation.
,, 2nd–4th (Frankfurt-a-Main).—Fifth Annual Meeting of the Society of German Neurologists.
,, 2nd–5th (Turin).—International Congress of Pathology.
,, 2nd–6th (London, Royal Horticultural Hall).—Seventh London Medical Exhibition.
,, 2nd–7th (Dresden).—Third International Housing Congress.
,, 2nd–7th (Paris).—French Congress of Surgery, Twenty-fourth Annual Congress.
,, 3rd–5th (Turin).—Ninth National Congress of Medici Condotti.
,, 3rd–6th (London).—Dairy Show.
,, 5th–7th (Paris).—Fifteenth Meeting of the French Association of Urology.
,, 6th and 7th (Paris).—French Association of Pediatrics.
,, 9th–12th (Turin).—Twenty-first Congress, Italian Society of Internal Medicine.
,, 9th–13th (Cologne).—Seventh International Congress of Criminal Anthropology.
,, 10th (Paris).—International Sanitary Conference (to Revise the International Sanitary Convention of 1903).
,, 12th–18th (Rome).—Fifth Annual Meeting of the Italian Society for the Advancement of Science.

Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. Galloway: Clinique (Skin).
TUESDAY.—4 P.M., Dr. N. Pitt: Clinique (Medical).
WEDNESDAY.—4 P.M., Mr. E. R. Carling: Clinique (Surgical).
THURSDAY.—4 P.M., Dr. F. J. Poynton: Clinique (Medical).
FRIDAY.—4 P.M., Dr. W. H. Kelson: Clinique (Ear, Nose and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. Bishop Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women.
THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. Bishop Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON), Clinical Theatre, London Hospital, Mile End-road, E.

MONDAY.—2 P.M., Demonstration in Clinical Medicine:—Dr. Wall: Pulmonary Diseases.
TUESDAY.—2 P.M., Demonstration in Clinical Medicine:—Dr. Grünbaum: Diseases giving rise to Morbid Renal Excretion.
THURSDAY.—2 P.M., Demonstration in Clinical Medicine:—Dr. Head: Diseases of the Nervous System.
FRIDAY.—2 P.M., Demonstration in Clinical Medicine:—Dr. L. Smith: Diseases of the Heart.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (25th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (26th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.). Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.). Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (27th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's 2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (28th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (29th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.)., Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (30th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1911, which was completed with the issue of June 24th, were given in THE LANCET of July 1st.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1911 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

The following journals, magazines &c., have been received:—Symons's Meteorological Magazine, Archiv für Experimentelle Pathologie und Pharmakologie, Report of the Bombay Medical Union, Cleveland Medical Journal, American Journal of Surgery, L'Hygiène, Prince Albert Hospital Gazette, Nordiskt Medicinskt Arkiv, Bulletin de l'Association Française pour l'Étude du Cancer, Philippine Journal of Science, British Journal of Dental Science, Gazette Médicale d'Orient, Pacific Medical Journal, American Journal of Obstetrics, Anti-Vivisection Review, South African Medical Record, Revue de Médecine, Revue de Chirurgie, Birmingham Medical Review, Revue de Gynécologie et de Chirurgie Abdominale, Heart, Interstate Medical Journal, Canadian Practitioner and Review, The Herb Doctor, Peru To-day, New Zealand Medical Journal, Yellow Fever Bureau Bulletin, and Australian Medical Journal.

Communications, Letters, &c., have been received from—

A.—Mr. W. F. Allen, Lond.; Messrs. Allen and Hanburys, Lond.; A. R. G.; Dr. George Adkins, Exeter; Automobile Association, Lond.; Apollinaris Co., Lond.; Messrs. Arnold and Sons, Lond.; Mr. R. J. Albery, Lond.; Dr. H. Russell Andrews, Lond.

B.—Messrs. Blundell and Rigby, Lond.; Mr. C. Birchall, Liverpool; Mr. W. G. Burcombe, Lincoln; Dr. F. G. Bennett, Chapel-en-le-Frith; Mr. T. Bouch, Lond.; Dr. W. Carnegie Brown, Lond.; Bury Infirmary, Secretary of; Mr. T. B. Browne, Lond.; Dr. L. E. Barrington-Ward, Lond.; Birmingham University, Dean and Faculty of Medicine of; Messrs. Bale, Sons, and Danielsson, Lond.; Dr. W. J. Butcher, Bedford; Miss C. S. Bremner, Bowerchalke; British Hospitals Association, Lond., Hon. Secretaries of; Bethnal Green Free Library, Lond., Secretary and Librarian of; Dr. W. A. Bullough, Wigan.

C.—Messrs. T. Christy and Co., Lond.; Coventry and Warwickshire Hospital, Secretary of; C. E. B.; C. J. S.; Camberwell Guardians, Lond., Clerk to the; Chicago School of Sanitary Instruction; Civil Surgeon; Messrs. J. and A. Churchill, Lond.; Mr. G. J. Cressy, Leominster; Messrs. Crossley and Co., Lond.; Mr. H. A. Collins, Croydon; Chemistry, Applied, Eighth International Congress of, Washington, President and Secretary of; Colonial Office, Lond., the Private Secretary of; Mr. Mayo Collier, Lond.

D.—Dr. J. L. Dickie, Cromer; Derbyshire Royal Infirmary, Derby, Secretary of; Messrs. Dyson and Wilkinson, Colwyn Bay; Dr. Haldin Davis, Lond.; D. G. D., Vichy; Dr. H. B. Day, Lond.; Mr. D. J. Duhig, Hornchurch.

E.—Messrs. Elliott, Son, and Boyton, Lond.; E. S. H.; Dr. C. T. Ewart, Woodford Bridge; *The Electrical Engineer*, Lond.. Messrs. Eyre and Spottiswoode, Lond.

F.—Messrs. Harvey Frost and Co., Lond.; Mr. O. Füssli and Co., Zürich; Dr. Henry Fraser, Lond.; Dr. R. S. Frew, Lond.; Mr. E. R. C. Fox, Glasgow; Factories, Chief Inspector of, Home Office, Lond.; Mr. Gustav Fischer, Jena.

G.—Guest Hospital, Dudley, Secretary of; Grimsby and District Hospital, Secretary of; Dr. Gamlen, West Hartlepool; Dr. E. W. Goodall, Lond.; Dr. Gubb, Aix-les Bains. Messrs. W. and A. Gilbert, Lond.; Professor J. A. Green, Sheffield; General Medical Council, Lond., President of.

H.—Messrs. T. H. Hewitt, Lond.; Mr. S. Heckscher, Hamburg; Hampstead General Hospital, Lond., Secretary of; Hunterian Society, President and Hon. Secretaries of; Mr. J. Hall, Manchester; Dr. C. L. Herman, Vienna; Mr. W. W. Horsburgh, Lond.; Dr. F. Hernaman-Johnson, Cockton Hill; Dr. R. L. Hammond, Woodsboro, Maryland; Hereford County and City Lunatic Asylum, Hereford, Committee of Visitors of; Miss Hamilton, Lond.

I.—India Rubber, Gutta Percha, and Telegraph Works Co., Lond.; Inspector-General of Prisons, United Provinces, Lucknow; Hon. Mrs. Ives, Halstead.

J.—Mr. R. Lane Joynt, Dublin; Mr. F. B. Jefferiss, Chatham.

K.—Messrs. R. A. Knight and Co., Lond.; Dr. Knight, Edinburgh; Messrs. H. S. King and Co., Lond.; Mr. Paul Katznelzon, Lond.; Kingston-upon-Hill, City Analyst of.

L.—Loughborough and District General Hospital and Infirmary, Secretary of; Leeds General Infirmary, Secretary of; Mr. H. K. Lewis, Lond.; Dr. H. A. Ledlard, Carlisle; Dr. C. Lillingston, Gorleston-on-Sea; Mr. W. M. Leonard, Boston; Messrs. Longmans, Green, and Co., Lond.; Local Government Board, Lond., Secretary of; London Hospital Medical College, College Board of; Messrs. R. Lehmann and Co., Lond.

M.—Manchester Royal Infirmary, Secretary of; Mr. R. Mosse, Berlin; Manchester Guardians, Clerk to the; Messrs. Meister, Lucius, and Brüning, Lond.; Mr. H. Morris, Birmingham; Medical Society of London, Hon. Secretaries of; Dr. Reginald Morton, Lond.; Manchester Corporation, Medical Officer of Health of; Dr. H. A. Miers, Lond.; Mr. George Moores, Manchester; Dr. F. W. Mott, Lond.; Dr. R. O. Moon, Lond.; Medical Missions Department, Society for the Propagation of the Gospel, Lond., Secretary of; Dr. Donald J. Munro, Lond.; Mr. A. Maude, Westerham.

N.—Mr. J. C. Needes, Lond.; Mr. H. Needes, Lond.; Nottingham General Dispensary, Secretary of; North Staffordshire Infirmary, Hartshill, Secretary of; Mr. S. C. Nag, Monocherra India; Dr. David Newman, Glasgow.

O.—Oxo, Lond., Manager Press Publicity of; Dr. Edward L. Oatman, New York; Mr. Joseph Offord, Lond.

P.—Messrs. Peacock and Hadley, Lond.; Players Motors, Ltd., Folkestone; Messrs. Pocock Bros., Lond.; Dr. Petit, Hyères-les-Palmiers; The Polytechnic, Lond., Director of Education of; Mr. C. Aubrey Pannett, Lond.; Messrs. G. P. Putnam's Sons, Lond.; Prestwich County Asylum, Manchester, Medical Superintendent of; Dr. G. A. Persson, Mount Clemens, Michigan; Dr. Edward E. Prest, Glenafton; Mr. E. R. Phillips, Leeds; Mr. H. A. Powell, Lond.

R.—Messrs. Reynolds and Branson, Leeds; Royal Hants and Southampton Hospital, Secretary of; Royal Devon and Exeter Hospital, Secretary of; Royal Portsmouth Hospital, Secretary of; Mr. H. Richardson, Lond.; Rochdale Infirmary, Secretary of; Dr. D. Ranken, Lond.; Dr. J. Robertson, Aberdeen; Registrar-General of Births, Deaths, and Marriages, South Australia; Dr. Amand Routh, Lond.; Mr. J. Ralston, Lond.; Rockefeller Institute for Medical Research, New York; Rationalist Press Association, Lond., Secretary of; Mr. Paul B. Roth, Lond.; Mr. Cecil Revis, Lond.; Royal Free Hospital, Lond., Secretary of.

A Presidential Address

ON

THE POSSIBLE TOXIC ORIGIN OF SOME KINDS OF INSANITY.

Delivered in the Section of Neurology and Psychological Medicine of the British Medical Association,

BY EDWIN GOODALL, M.D., B.S. LOND., F.R.C.P. LOND.,

MEDICAL SUPERINTENDENT, CITY OF CARDIFF MENTAL HOSPITAL.

GENTLEMEN,—It is well known that mental disorder can be produced by intoxicants (alcohol, cocaine, haschisch). It also occurs in connexion with such diseases as influenza, erysipelas, pneumonia, typhoid fever. When so occurring it cannot be always explained as due to fever or exhaustion, since it comes on in the pre-pyrexial stage (as in typhoid, variola), or the apyrexial stage (as in malaria). In these cases the mental disorder must be ascribed to a toxin.

The clinical and anatomico-pathological descriptions of various writers (Martin and Ringenbach, Franca and Anthias Spielberger, Mott, and others) show a considerable resemblance between the symptoms due to the trypanosome-toxin and those present in paralytic dementia, and some resemblance in the cerebral lesions. With sleeping sickness there is more fever. No remissions occur, I believe, in this disease, in striking contrast to general paralysis; on the other hand, I believe there is a lymphocytosis in it. As to the occurrence of the same in paralytic dementia, *vide infra*. That acute delirious mania, acute hallucinatory and confusional states are due to toxæmia is freely assumed, but has not been demonstrated.

BACTERIOLOGICAL WORK IN INSANITY.

Most of the observations as regards micro-organisms in the circulation in mental diseases are isolated and unsystematic. Most of the cases I have personally examined gave negative results, but I have found diphtheroids and cocci in general paralysis, acute delirious mania, and acute mania and melancholia. In these cases there was no known source of secondary infection. The organisms found in the blood and cerebro-spinal fluids by various workers are bacilli, including diphtheroids and B. coli, diplococci, short chains of streptococci. Acute delirious mania has been specially investigated, and by Italian workers (Rasori, Ceni, Bianchi, Piccinino). Workers in this country on the subject of the circulation of micro-organisms include Lewis Bruce, Ford Robertson, McRae and Jeffrey, Candler, Marr, Muirhead; in America, Gay and Southard. The three last-named writers have published the most systemetic work I am acquainted with.

Summarising the work of the past 20 years I should affirm that there are no adequate grounds for believing that the organisms which have been found in the tissues in any case of insanity play more than a secondary rôle. At the same time, they frequently cause death. (We fall victims, it has been said, most often to our secondary infections.) Though not shown to be of prime pathological significance, they may yet be shown to be the cause of some of the symptoms. Much more work is required in this field, and better methods of cultivation of organisms are needed.

Apart from the demonstration of diphtheroids in association with inflammatory changes in the mucosa of the digestive and respiratory tracts in general paralysis (Ford Robertson), it has not been shown that there is a local source of infection in the mucous tracts or elsewhere, such as occurs in diphtheria and tetanus, in any of the insanities. It is a pure assumption that catarrhal enteritis provides such a local source (as described by Pardo). We do not know how the mental symptoms, which are undoubtedly due to disorder of the digestive functions, with its attendant constipation, which disorder occurs in recent insanity and in exacerbations of chronic insanity, are produced. Still more marked digestive disturbance, with prodigious constipation, and symptoms of auto-intoxication, occurs in cases of intestinal stasis prior to relief by short-circuiting, and yet without mental disorder (the *irritabile* is wanting). That there is disordered action of the digestive juices, and also impaired peristalsis in some mental disorders, has been proved by Pardo and Benigni, and can be shown by adequate physico-chemical examination of the stools in these cases.

We are not yet justified in saying, as certain Italian writers, more especially, do, that the presence of indigo in the urine is evidence of toxæmia of intestinal origin, much less in attempting to correlate its presence with symptoms of insanity. We cannot yet estimate the indigo quantitatively; hence no normal standard exists.[1] Various medical books tell us that the substance in the urine which on oxidation gives indigo is indoxyl-sulphate of potassium, the precursor of which, "indigogen," is indol, which, again, is produced from tryptophane by the action of intestinal bacteria; that the "abundant presence" of indigo testifies to the activity of protein putrefaction. This naturally affords the basis for an attractive theory of auto-toxæmia in some kinds of insanity. But how can a thing be said to be "abundantly present" which cannot be quantitatively estimated? And I believe we must be candid and admit that we do not fully know what the precursors of indigo are, whether they are all derived from the intestinal contents or not.

As regards the bacteriology of the fæces in mental disorders, I am not aware of any work other than that of the Italian observer, Pardo. The following is a mere summary of work yet to be published, carried on by Mr. E. Barton White and myself at the Cardiff Mental Hospital during the past two years. One gramme of fæces from cases of acute mania and melancholia was examined in each instance, using decimal dilutions of an original solution of 1 in 100; as a control, the results with normal stool obtained by Dr. A. C. Houston of the Local Government Board were used. Cases examined, 23; total bacteria increased in 39 per cent., diminished in 26 per cent.; B. coli increased or diminished to like extent, whether as typical or atypical forms requires further investigation; the anaerobe, B. enteritidis sporogenes (? B. welchii in some cases), diminished in all but one case (in which the amount was normal), often greatly diminished; B. putrificus not found; spores of aerobic bacteria diminished in 76 per cent., in none increased; colonies isolated on agar-fuchsin made up practically of B. coli, typical in 80 per cent. of cases; the micro-organisms found were, with a few possible exceptions, those of normal stools; agglutination of B. coli very rare, and when present equal with homologous and heterologous serum. (These results agree with those obtained in 82 cases of acute mania and melancholia by Dr. Alice Johnson and myself.[2])

As far as evidence based upon formation of agglutinins goes, B. coli is neither in circulation nor responsible for any toxin which may be. But evidence based upon complement-fixation and the opsonic index is also required. Streptococci: 13 cases examined; increased in 7, diminished or absent in 4, in normal amount in 2. Our work lends no support to the statement of Pardo that the putrefactive anaerobes are increased at the expense of B. coli and B. aërogenes, the normally preponderant organisms; nor to the statement that streptococci preponderate. It is evident that much work has yet to be done in the bacteriology of stool in the acute insanities, to say nothing of physico-chemical research.

Let it be noted that Metchnikoff and his pupils have shown[3] that the three chief putrefactive anaerobes found in the human intestine produce toxins which are absorbed by the mucosa of the large intestine.

Work on the opsonic index in insanity has been done by Shaw and by Babington, who show that the index is lowered, in the acute insanities especially, to such common organisms as B. coli, staphylococcus aureus, streptococcus fæcalis, B. tuberculosis. Baccelli and Terni find a raised index in epilepsy, a normal one in dementia præcox. A greater liability to secondary infections is perhaps all this implies, such as we see in other conditions of lowered resistance—for example, diabetes, chronic nephritis.

Although there is clinical evidence of toxæmia in the so-called "intoxication-psychoses," with the exception of acute delirious mania it cannot be maintained that there is evidence comparable with that furnished by a case of pneumonia or one of the common infectious fevers. The

[3] Annales de l'Institut Pasteur, 1908, tome xxii.

hypothetical toxin in the former instances must be of a lesser degree of virulence. Hence disordered metabolism is postulated as the cause of insanity, by way of auto-intoxication.

LEUCOCYTOSIS IN MENTAL DISORDERS.

The outstanding pathological fact which indicates a toxic pathogenesis for some of the psychoses is leucocytosis. The condition is found very commonly in acute and recent mental disorder, and in states of exacerbation during chronic insanity. The most recent workers in this field are Dide and Chenais, Klippel and Lefas, Lepine and Popoff in France; Lewis Bruce, C. MacDowall in this country; Heilemann in Germany; Graziani in Italy. I believe the following statements are justified by much personal study of this question for the past three years and by the work of these investigators. The total leucocyte count is increased in varying amounts from 11,000 to 30,000 per cubic millimetre in acute and recent mania and melancholia (senility excluded), and in the periodic exacerbations of chronic cases of the same. Should the count fall in the course of the disease it rises again to rather above normal towards the close of the attack in cases which recover, and remains fairly high on recovery. In acute mania and melancholia the percentage proportion of the neutrophile cells is increased in the early phases of the disease, also towards the close of the attack when recovery is to take place. In these disorders a low total count and a fall in the normal percentage of neutrophiles, if maintained, are of bad augury, and point to the onset of dementia. As regards dementia præcox, in the active phase there is some, but no considerable increase in the total number of leucocytes; neutrophiles are diminished, and lymphocytes, mononuclears, and eosinophiles increased. Cases of systematised delusional insanity do not exhibit leucocytosis.

As a generalisation, in the acute and recent mental disorders there is leucocytosis with percentage increase of the polynuclear cells; in the subacute and chronic ones there is little or none, and the proportion of large mononuclears and lymphocytes is increased. In acute mental disorders absence of leucocytosis and a fall in the percentage-proportion of polymorphs go with deficient reaction, and are an unfavourable indication, as is the case in those infectious fevers in which leucocytosis is observed. This, from the standpoint of toxæmia, is significant.

In regard to paralytic dementia, in the first period, while still the patient is well nourished and active there is leucocytosis with proportional increase of neutrophiles; in the succeeding periods lymphocytes and mononuclears are increased at their expense, but it is to be noted that, even in these, exacerbations are accompanied by a rise in the neutrophile count. In six cases of well-marked remission recently examined by me the lymphocytes, transitional cells, and mononuclears (especially the last two varieties) were notably increased at the expense of neutrophiles. (Incidentally, three showed eosinophilia.) My friend, Dr. H. A. Schölberg, pathologist, of Cardiff, reminds me that in protozoal maladies (sleeping sickness, syphilis, malaria) the reaction of the white cells towards infection is by lymphocytosis, not leucocytosis. If further experience shows that there is the same reaction in general paralysis a point of great significance will have been made out. The Wassermann test shows that in general paralysis we have a disease which is syphilitic *au fond;* its essential cause becomes, I think, again operative under privation and stress; further evidence of this may be found in the mode of reaction of the white cells (lymphocytosis). We should then look upon the polymorphonuclear increase as merely a reaction to a secondary infection, such as would cause acute phases and exacerbations in the malady. If this line of reasoning prove correct an explanation would be available for the favourable results reported by von Wagner and Pilcz, of Vienna, who prolong remissions and ameliorate the disease by injections of tuberculin, for by this means lymphocytosis is promoted. There is no mention of the state of the white-cell count in the papers by Pilcz which I have consulted.

We have still no safe and reliable means of bringing about recovery in mental disorders, such as is seen in connexion with intercurrent disease (for example, pneumonia, erysipelas, cellulitis), in association with fever and hyperleucocytosis. Turpentine, yeast, cinnamate of soda, sodium nucleinate (introduced by Donath of Budapest and Fischer of Prague), all are unsatisfactory. The "reaction" is not pronounced enough, nor does it last long enough. Some of us are seeking to elaborate other methods, of which it is too soon to speak.

OBSERVATIONS ON METABOLISM.

In conclusion, the following few observations on mental disturbances in autotoxæmia. Such, amounting to insanity in predisposed persons, occur in various maladies in which the nutrition is impaired, or in which metabolism and depuration are altered or hindered. Thus, in diseases of the heart, kidneys, liver; in rheumatism, gout, or chlorosis; in diabetes. We know that the like mental disturbances are found with Graves's disease, myxœdema, Addison's disease (ductless gland diseases). In the hypothyroidism of myxœdema Magnus Levy shows experimentally definite deviation from normal metabolism, removed by administration of thyroid. As the symptoms (including the mental ones) disappear or are greatly mitigated by such means, there is reason for the view that metabolic disorder accounts for the mental disturbances in this disease, and if in this, then also, it may be, in other ductless gland diseases. When, however, it comes to administering thyroid or pituitary gland in kinds of insanity in which there is no ground for supposing the action of these glands to be deficient, in order, as the jargon goes, "to promote metabolism," we are empirics indeed; yet, like empirics, we sometimes do good in this way. Is there any record of the metabolism in these cases before, during, and after treatment?

Some sporadic work in metabolism in the insanities has been done: thus, in dementia præcox (Pighini); in epilepsy and general paralysis (Kauffmann)—work in need of confirmation. For systematic work we have, I believe, still to refer to Folin (Maclean Hospital, Massachusetts), whose observations were concerned with the urine, and amount to this: that unusual fluctuation in the urinary constituents occurs in general paralysis, which strongly suggests that this may be at one stage or another associated with disordered metabolism; as regards other mental disorders, individual peculiarities indicating abnormal metabolism are frequent, but no characteristic metabolism corresponding with a particular disorder has as yet been found. I may further mention researches upon the excretion of creatinine in the insane conducted by Mr. MacKenzie Wallis and myself, and subsequently by the former at Cardiff Mental Hospital. These, and especially the last-mentioned research of Mr. Wallis, show that the excretion of creatinine, which in normal persons is practically constant for the individual from day to day, and independent of diet, varies from day to day in several kinds of insanity and is subnormal (as is also the coefficient, creatinine-bodyweight). This variation has so far been found only in mental cases. These researches point to altered muscle-cell metabolism in the insane, and indicate by a special instance the need for further inquiry into questions of metabolism in mental disorders—the need, in other words, of the physiologist and the chemist in mental hospitals.

THE SURGICAL TREATMENT OF SOME FORMS OF EPILEPSY.

BY WILLIAM ALEXANDER, M.D.R.U.I., F.R.C.S. ENG.,

ACTING CONSULTING MEDICAL OFFICER TO THE MAGHULL COLONY FOR EPILEPTICS; CONSULTING SURGEON, ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

Introductory Remarks.

IT is now fairly well agreed upon that the seat of idiopathic epilepsy is in the grey matter that covers the convolutions of the cerebrum and that the "fault" lies in some way in the cortical brain cells of this region. Many generations of observers have closely scrutinised the cortex of the brain, yet in spite of the much greater delicacy of our instruments and of improved technique, we seem to be as far as ever from the discovery of any definite change in the nerve cells likely to be associated in causal relations with epilepsy. As the results of experiment and of disease alike point to this region and to the cortical cells, we can only conjecture what the changes in the nerve cells may be.

Hughlings Jackson assumes an unstable condition of the

nerve cells through which a liberation of nerve force takes place either spontaneously or under the influence of causes that are insufficient to liberate the nerve force of healthy cells, and hence the discharges of the cortical cells in epilepsy are irregular, premature, and objectless, the very opposite qualities to those which characterise healthy discharges of nerve force. Hughlings Jackson, also in illustration of his theory, speculates that the unstable grey matter of disease is of the same constitution as the comparatively stable grey matter of health, but of a different composition; and a further speculation is that the phosphorus ingredient is replaced by its congener nitrogen, and that the nervous matter is more nitrogenised and therefore more explosive.

Broadbent thought it must be assumed in ordinary epilepsy that the nutrition of the grey substance is modified so as either to give rise to excessive production of a normal explosive matter, or to the formation of a more deteriorated and more unstable variety. The grey matter forming the cerebral cortex is intellectual, receiving centripetal impulses, dealing with them and transmitting the information so received into efferent impulses. In epilepsy it is also supposed that cortical nerve cells may spontaneously produce motor discharges without sensory influence, or may produce irregular discharges at the stimulation of sensory afferent influences of a slight character, such as intestinal influences, mental worries, memories, &c.

Gowers thinks epilepsy to be due to an abnormal state of chemical nutrition whereby the molecules are more easily detached and their atoms yield with undue facility to the attractions of the adjacent oxygen. Haig assumes an alkaline tide during the night and early morning, when uric acid is supposed to circulate freely in the blood and to produce migraine, mental disease, and epilepsy.

A. E. Russell suggests that failure of the cerebral circulation has something to do with the production of epilepsy. Peripheral irritation, such as dentition, injuries of nerves, intestinal irritation produced by unsuitable or excessive diet, worms, constipation, menstruation, are dwelt upon as sufficient causes by other observers. These peripheral irritations, as far as we know, are not greater than similar irritations that occur in normal non-epileptic individuals, and hence an unstable nervous system has to be assumed; and such a theory when followed up resolves itself really into that of the Jacksonian unstable cortical cell theory. These are all theories that explain the phenomena to a certain extent, but do not lead to any practical issue, or when put to the proof do not help towards the relief of the patient.

What is the cause of the instability of the cortical cells is the next question that naturally arises. Is it hereditary or is it acquired? If it is hereditary, in Dr. John Turner's sense "of an inherently defective nervous system from an hereditary vicious organisation," then the outlook is hopeless for the individual epileptic, and our only remedy is eugenics and the limitation of the class. But no one, even the most extreme advocate of heredity, can find distinct evidence of ancestral disease in more than 40 to 50 per cent. of epileptics, and we continually meet with cases where traumatism plays an undeniably prominent part in the production of the disease, and where no heredity has existed within the remotest periods of time available for inquiry. Heredity probably means no more in epilepsy than it does in tubercular phthisis—viz., a deficiency of resistance to the particular agency by which the disease is produced. Should the agent be absent the individual does not become an epileptic, but the presence of the agent connotes epilepsy. In perfectly normal individuals, as far as anyone can say, a sufficiently powerful agent may produce the disease. Most epileptologists and surgeons have met cases where healthy well-balanced men or boys have become subject to epilepsy through traumatism, and the nervousness that often characterises the traumatic epileptic is the result of the disease instead of a predisposing cause. A change has taken place in the brain cells in such cases so slight and so obscure as to elude detection by our most expert methods of examination, and the subtle change may persist during a lifetime or may disappear after a few epileptic manifestations. The question arises in my mind whether we are not aiming too high in trying to find out the minute change or changes in the cortical cell that induce epilepsy. Such a change may be largely psychical and its detection may for ever be beyond our powers, just as the question, What is life? is still unanswerable. We know what life does and we know something about circumstances that will influence or destroy life, and a study of such causes is well worth while, although a comprehension of the mystery of life will probably never be attainable by mortal man. So it is with electricity; so it may be with epilepsy. In this way it seems to me that observations of the phenomena of epilepsy in the post-mortem room and in the operating theatre have suffered. Obvious naked-eye lesions have been ignored or passed over in a sentence as of no moment, and nerve cells have been stained, magnified, and scanned for changes. If any minute changes could be found constant in epilepsy, and peculiar to that disease, it would probably not advance either the welfare of the sufferers or our knowledge of the causes and nature of the disease in the smallest degree.

Importance and Prevalence of Œdema of Pia-arachnoid in Epilepsy.

About ten years ago, while exploring the brain in cases of focal epilepsy where no gross lesion was found, I was struck by the constant presence of œdema beneath or in the pia-arachnoid. This œdema was flocculent and hazy in appearance, sometimes completely concealing the contour of the cerebral convolutions, at other times only rendering it dim. On pricking the arachnoid the fluid ran out clear and pellucid or sometimes spurted out as if under tension. On collection and examination it answered all the tests of cerebro-spinal fluid. I began to look for it in necropsies on epileptics, but did not find it there so frequently or so distinctly, although in some cases of status epilepticus it was very manifest, as in the following case. The patient, a woman aged 45, who had been an epileptic for 20 years, suffering from both *grand mal* and *petit mal*, and died in "status" of 48 hours' duration, showed a marked layer of œdema over the motor area on both sides of the encephalon. There was very little over the frontal lobes. The occipital lobes and the base were quite free from fluid. Knowing now where to look for it I can see traces of it generally in all post-mortem examinations. It is, however, on the operating table that it obtrudes itself upon our notice, and I now look for it in all my operations in epilepsy and find it as a matter of course. I have demonstrated it for the past ten years to many students, house surgeons, and medical visitors, so that there is no doubt of its existence. The condition found in each case has been described sometimes by myself, sometimes by my house surgeon or dresser in the clinical notes, some extracts from which in regard to the presence of fluid may here be given.

Extracts taken Verbatim from Notes of 20 Successive Cases of Epilepsy where the Brain was Exposed by Trephining and which show the Presence of Œdema of the Pia-arachnoid in every Case.

1. F. S., aged 10, an epileptic since one year old; attacks daily, one or more; aura, twitching in right hand; operation; no gross lesion found, but a dense layer of grey flocculent fluid covered the left motor area and concealed the convolutions. A thin membrane covered the fluid. The membrane was readily removed by traction with the forceps, and the fluid ran away in a considerable quantity, after which the convolutions could be distinctly seen.
2. J. W., aged 7, a congenital epileptic with daily attacks; right aura. The motor area of the left hemisphere was found to be very œdematous and bulged through the fenestration made in the dura mater. In subsequent cases the notes regarding the œdema only will be given.
3. "There was considerable œdema on each side of the vessels, especially posteriorly."
4. "Some fluid escaped."
5. "Brain looked pale and œdematous as seen through the fluid which escaped and was caught for examination."
6. "When dura opened, meninges found in the usual œdematous condition."
7. "Large amount of clear fluid found and came away."
8. "The dura was incised and the fluid ran out in considerable quantity."
9. "When the tense dura mater was opened a large quantity of clear fluid was evacuated, leaving brain quite clear."
10. "The brain below looked congested and œdematous."
11. "Membranes very œdematous; a large quantity of clear fluid came away."
12. "There was a large quantity of fluid along the vessels, slightly turbid and coming away freely."
13. "Usual œdema found on surface of brain."
14. "Trephined on left side. œdema on surface of convolutions."
15. "Dura mater fenestrated; contained much fluid beneath membranes."
16. "Usual œdema found on surface of brain."
17. "There was a great deal of fluid along the vessels, slightly turbid oozing away freely when the membrane was opened."
18. "Arachnoid contained clear fluid and was rather œdematous."
19. "Brain surface very œdematous."
20. "Surface of brain œdematous and somewhat hæmorrhagic."

Extracts Corroborating the Prevalence of Œdema of the Pia-Arachnoid in Epilepsy by Other Observers.

It would seem strange if this phenomenon of œdema had not been noticed before, and a perusal of the medical journals for some years shows that it has been observed again and again. Dr. John Turner writes about "the abundant foam-like exudate as a feature constantly present in epilepsy." It is found, he says, in small quantities in other diseases, notably general paralysis of the insane, a disease occasionally, if not frequently, accompanied by epileptic seizures. Dr. Bendandi, Bologna, opened the skull of a traumatic epileptic; a tablespoonful of colourless fluid was found on the surface of the brain (localised œdema). Dr. Lees and Mr. Page describe the milky arachnoid in a case of epilepsy and a large excess of subarachnoid fluid.

Dr. H. Muir Evans of Lowestoft, in describing a case of trephining for focal epilepsy, says, "When dura mater incised crucially a large amount of cerebro-spinal fluid escaped, and the arachnoid looked as if a mucous polypus was flattened on the surface of the brain." Dr. A. E. Morison, in operating upon a traumatic epileptic, says, "Arachnoid bulged and was excised, when 2 ounces of straw-coloured fluid pent up in a localised space escaped." In a second case blood was effused beneath the arachnoid. Sir Henry Butlin trephined in a case of traumatic epilepsy and found a small clot of blood in the subarachnoid space, and beneath there were two to three drachms of fluid. Dr. F. T. Heuston of Dublin refers to the increase of cerebral fluid in a case in which he trephined and where there were traumatic epilepsy, aphasia, and paralysis. Sir Thomas Oliver trephined on the right side. Several teaspoonfuls of serum with flakes of lymph escaped, the dressings being soaked at the first dressing.

Dr. Spratling, in his work on epilepsy (p. 315), says the pia mater presents frequent changes in epilepsy, but none which are constant and characteristic. Of these the most frequent is a certain amount of œdema and congestion of the pia, the latter being a sequence of the vascular engorgement incident to the fit; a certain amount of œdema is quite common, and is especially pronounced in old epileptics and insane epileptics, and is often associated with more or less brain wasting and incidental increase in the cerebro-spinal fluid. In his directions for operations Dr. Spratling says that at times the pia may be so œdematous as to obscure the outlines of the convolutions. In such cases it will be necessary to "incise the pia to allow of the escape of the fluids."

Extent and Character of the Fluid Found.

The evidence of the frequent if not constant presence of this fluid over the motor area in epilepsy is therefore very strong. The extent of the area involved is not so certain. My operations have always been directed to the focus indicated by the unilateral spasms, which I made the centre of a large opening over all the suspected motor area, and there the œdema was always present. What was the condition of the other parts of the brain in these cases I cannot say, as it is only in necropsies that the whole brain is uncovered, and in necropsies the fluid is not so much in evidence, but in the case of status already described it was found over the motor areas of both sides of the brain and scarcely at all anywhere else. The convulsions were general in this case. The fluid is clear, sterile, milky, or frothy in appearance, and contains small particles of lymph that cause the fluid to appear like thin barley-water. The brain has a glossy look as seen through the fluid, and when the layer of fluid is deep the convolutions beneath are concealed. The fluid runs away quite clear, the small particles of lymph remaining *in situ*. Sometimes large quantities of fluid drain away after operation. Bacteriological examinations fail to show any organisms, and chemically the fluid is pure cerebro-spinal fluid. The membranes of the brain are not generally thickened or altered from their normal appearance.

Circumstances and Experiences Connecting this Œdema with Epilepsy as a Probable Cause.

What connexion has this pia-arachnoid œdema with epilepsy? Probably the great majority of observers would have said none, and most likely many other observers have noticed it, but not thinking it of any importance have not reported it, or have come to the conclusion, like Dr. Spratling, that it is a result of the fits. When it caught my attention about ten years ago during an exploration for so-called focal epilepsy there were several circumstances that forced me to consider it very closely. Amongst these was, first and foremost, that eclampsia, a disease characterised by œdema all over the body, has epileptiform convulsions as one of its main characteristics. Secondly, the frequency with which scarlet fever is followed by epilepsy, a disease in which dropsy is not uncommon. Thirdly, the sudden and mysterious onset of œdema of the lungs in epilepsy, as proved by both clinical and pathological evidence. This œdema of the lungs is also found in eclampsia, and is no doubt a part of the circulatory changes that produce the cerebral œdema. Fourthly, the great benefit in many cases of trephining, especially those cases where a considerable area of the calvarium had been removed and where possibly an equilibration of tension was the secret of the relief obtained. I say advisedly *equilibration of tension* because I have strong reason to believe that a decrease of tension rather than an increase may be the cause of the œdema.

Experimental and Clinical Evidence to Show that Œdema may Cause Convulsions.

We have not much reliable experimental evidence to bring forward, but we find that Flourens wounded the dura mater in young pigeons and showed that the convulsions were produced by the extravasation of blood and were relieved by opening the cranium. Leyden drove albuminous fluid into the cranial cavity of a lightly morphiamosed dog when cries, convulsions, and irregular respiration occurred.

I will briefly relate several experiments that Nature may be said to have performed for me lately and which strongly corroborate and support my ideas—formed upon the results of operations and post-mortem examinations—as to the causative functions of œdema in connexion with epilepsy.

CASE 1.—A man, aged 35. Admitted to hospital May 17th, 1910. The previous day he had been driving a cart which came into collision with a tramcar. He was thrown out of his cart, and sustained bruises on both sides of his head. The patient was at first dazed and unable to speak. He had been more or less of an invalid for years, suffering from epistaxis and occasionally hæmoptysis, phthisis, and had a severe cough on admission. For the three days after admission he gradually became more unconscious until the 20th, when he was noticed to have attacks of twitching on the right side of the face and limbs. The first attack occurred at 1.30 P.M. and lasted three seconds. The next occurred 20 minutes later, and from that until the operation the attacks occurred every 20 to 30 minutes till 6 P.M., when they became more severe and more frequent. I diagnosed a collection of fluid over the left motor area, and on May 17th removed a rhomboidal piece of bone (3 × 2 in.) that exposed the dura mater over the central zone of the whole motor area. On fenestrating the dura mater a large quantity of blood-stained fluid was found both beneath and above the arachnoid, and the convolutions beneath were deeply stained red. The fluid was allowed to flow away. The bone was not replaced, and the skin flap was laid down over the fenestrated dura mater, a thin curved glass drainage-tube being inserted at the back of the wound and passed between flap and dura. The wound was then stitched up, not a single ligature being required. A large dressing of sterilised gauze and wool was applied and kept in place by a capeline bandage. Immediately after operation, and during the night, patient had nine fits. There were no fits on the 21st nor during the remainder of his convalescence. The dressings became saturated with fluid, and were covered with fresh layers of gauze and wool. The patient was rather restless in the evening. The temperature went up to 103° F. Some morphia was given. May 22nd: Temperature 100° in morning, wound dressed, drainage-tube removed, dressings saturated, no more twitchings, but restless and tried to pull dressings off. 23rd: He began to speak, and said "Yes." From this time till his discharge his speech gradually came back. The wound healed by the first intention, and he was finally discharged on August 1st, 1910. The state of his chest detained him in hospital long after he was well of the head injury, and gave us ample time to watch the return of his speech and the complete and rapid disappearance of his attacks. The only thing we had done was to drain away the fluid that we found over the motor area and to leave openings by which fresh fluid could drain into the surrounding tissues.

CASE 2.—A man, aged 50, was admitted to hospital on Oct. 1st, 1910, and reported to me as having had an injury on the left side of the head. When admitted he had aphasia and gradually increasing unconsciousness; epileptiform attacks were frequent. Mouth twitched to right side and right arm stiff and rigid. Late in the evening of the day of admission he was trephined over the left motor area. The skin over the left parietal eminence was much bruised, but the bone beneath was not injured. On removing a rhomboidal area as in the last case and fenestrating the dura mater we found a considerable flocculent œdema, not blood-stained, that entirely concealed the brain beneath. It looked like the condition of an epileptic. The pia-arachnoid was punctured, the fluid evacuated, the flap closed as before, and a similar drainage-tube was also inserted. Next morning the patient was quite conscious, the aphasia had disappeared, and the temperature was normal. I was puzzled by this case, especially in regard to the fluid being flocculent and not blood-stained, until I found that the patient was an old epileptic, and that probably the blow that he had received had increased the amount of fluid that already was in excess, and hence the acute and grave symptoms that he presented after admission. The case illustrates the rapid beneficial effect of removing the fluid and the cessation of the localised twitchings that were almost continuous just before the operation.

CASE 3.—My next case is one of *puerperal eclampsia*. The patient, aged 35, was confined ten days before her admission on Sept. 11th, 1910. Ever since her confinement she had incessant headaches, and the day before admission she had ten severe fits, as a result of which she was completely unconscious and cyanosed. In spite of remedies she remained in a hopeless condition. On the 12th, as the fits were distinctly right-sided and, as a last resource, I trephined over the left motor area and found such an amount of œdema and turgescence of the veins as I had never witnessed before. The pia-arachnoid was punctured, much fluid came away, and the wound was drained and closed in the usual way. A few hours after she seemed to be rather more conscious, but her pulse was extremely feeble, and her condition still very hopeless. She died 12 hours after operation from coma and exhaustion. The temperature had risen to 104·4° F., *but no fits and no twitchings had taken place after the operation*. A necropsy showed the operation wound and brain quite aseptic; minute, sometimes confluent, hæmorrhages had taken place into the convolutions of both the right and left sides of the brain over the motor areas, on the left side more especially.

These three cases are given to show the effect of simple removal of the fluid. In each case nothing was done but remove the fluid, and in them all the twitchings stopped almost at once and did not return. The other symptoms also disappeared in the first two cases, but in the eclamptic the hæmorrhage into the substance of the brain was too extensive to permit of recovery. I only mention the last case to show that even there the twitchings were probably the result of the fluid rather than of the hæmorrhage into the brain.

Efforts to Relieve the Disease Founded upon the Foregoing Considerations.

We have endeavoured to relieve our patients by the removal of the œdema, and in order to do this we have, in the first place, to diagnose the seat of the œdema by means of the aura in cases where it occurs. Where it is a distinct and fairly constant phenomenon we cut down upon that area of the brain, fenestrate the dura mater, and so open the pia arachnoid. The bone is not replaced, but the skin flap lies over the fenestrated dura, and thus a free communication is made between the general peripheral circulation and the cerebral cortical circulation. A safety-valve action is thus afforded the enclosed cerebral circulation and tension is equilibrated and the œdema can drain away as soon as it is formed.

There are many theories to explain the benefits of the operations, but I do not intend to dwell upon them here, knowing how fragile most theories are to lean upon. What we depend on are the facts, showing what benefits epileptics have derived from such operations and what disadvantages, if any, have resulted from the same.

The operation, which is named "*fenestration of the dura mater*," consists of a definite procedure not to be confounded with any other procedure that we have ever heard of. It is not merely trephining, although we have to trephine to reach the cerebral cortex, and some writers and surgeons have confounded fenestration with trephining, and talked as if we were performing an old operation that no longer interests the medical world. In a few cases trephining and removal of large areas of skull have been followed by much success, and we have published one or two good examples that are scattered through different journals, but they are unique cases, and that operation cannot be considered as a successful routine treatment for epilepsy. Then we have trephining, removal of part of the calvarium, opening of dura and exploring for tumour, diseased convolutions, spicules of bone, removal of such lesions when found, and replacement of dura and bone and complete closure of the wounds, &c.

In "fenestration of the dura mater" we do not operate with such intentions. We do not *expect* to find any such lesions, but should any exist we treat them, but only very exceptionally do we find any. We operate to find œdema of the pia-arachnoid, and we presume a condition of malnutrition of the grey matter of the cortex produced by the œdema sufficient to keep up the epileptic phenomena, and by draining this area we hope to improve the nutrition of the deranged cortical cells and diminish the number of attacks, improving the prospects of the cure of the patient. This is what we mean by fenestration of the dura mater, and to apply the general term of trephining to such an operation is misleading.

The operation was "led up to" by the ordinary trephining or exploratory operations. In these my custom was to stitch up the dura in deference to the general practice, but I found at times and for various reasons that it was impossible to stitch up the dura completely and fenestrations were accidentally left and that these not only did not interfere with the surgical success of the case, but even sometimes coincided with a greater therapeutic success than in the cases I was able to stitch up to my satisfaction. Hence, when the idea came to me of making the fenestrations the important part of the operation, I was not taking a leap in the dark, but was quite assured by previous operative experience not only of the safety of the procedure but of its probable beneficial effects. The following is a description of the operation performed by me for several years.

Description of Operation of "Fenestration."

The scalp is shaved two days before operation, thoroughly washed and scrubbed with ethereal soap and ether, and a lotion of hydrarg. perchloride 1 in 1000 is applied for 24 hours. Then a similar process is carried out, the perchloride being applied for another 24 hours. On the operation table the head is surrounded with aseptic towels and all essential aseptic precautions are taken to render the operation a success. A large flap of the hairy scalp containing all structures down to the bone is thrown over the ear, which is protected by a sterilised towel. This exposes the skull from the frontal to the occipital bone and from below the middle line to the temporal muscle. The bleeding from both sides of the incision is quickly stopped by the application of Thornton's transverse bladed forceps. The skull is now cleared of periosteum above the parietal eminence and two trephine holes made, one in the front part and one in the back part of the parietal bone and about midway between the level of the parietal eminence and the median line. A Hey's saw joins these trephine holes. The bone half sawn through is cut out by bone forceps; it makes a rectangular opening 4 by 3 in. The size will vary according to the size of the skull, but I always err on the side of excess rather than of deficiency of room. The safety of the patient is manifestly promoted by leaving the parietal eminence intact. Before cutting with bone forceps it is always well to see that the dura mater is not adherent to the bone at any part. When the bone is removed the dura mater crossed by its branching vessels comes into view. It is opened very carefully by a small aperture so as not to puncture any delicate vessels beneath. A director may then be passed in and the dura slit up from side to side in three or four places as far as the dural vessels will permit. The state of the pia-arachnoid and of the brain beneath may then be conveniently inspected over the whole area, 4 by 3 in. The pia-arachnoid may be opened in various places and the fluid allowed to run away. A stream of normal saline refreshens and washes the wound, and the flap similarly freshened is laid back in position with the forceps still attached. The surgeon, beginning at the anterior end of the wound, stitches it up with a continuous suture of silkworm gut, the assistant removing the forceps as he advances until the whole wound is quite stitched up. The cicatrix lies over the solid bone, and the pressure of the suture and afterwards of the dressings produces complete hæmostasis, so that not a single ligature has to be used throughout the operation unless the surgeon is so unfortunate as to wound a pia-arachnoid vessel in opening the dura mater, when a fine ligature may be necessary and is difficult to apply owing to the frailty of these vessels. A fine curved Kocher's drainage-tube, with small elevations at the outer end to prevent it passing beneath the flap and out of sight, is now inserted at the posterior end of the wound and passed between the dura mater and the flap. Sterile gauze and sterile wool dressings are now applied in profusion and held firmly in position by a well-applied capeline bandage. Great care is necessary in nursing to see that the patient does not interfere with the dressings and that fresh wool is applied at once where discharges show. In 48 hours the dressings are taken down, the glass tube removed, and the dressings re-applied and allowed to remain until the fourteenth day after operation, when the sutures are removed and lighter dressings applied for another week. Afterwards a soft cap is all that is necessary, stiffened by a thin piece of poroplastic material a little larger than the size of the opening. It is only necessary that this stiffening should be fastened inside the lining of the cap and over the weakened part of the calvarium. It is quite as effectual in warding off blows as a silver plate fixed over the trephine opening. It should be worn for some months, especially during play, or when circumstances render its use advisable.

Results of Operation.

I will now give the results of operation up to date in 20 cases that we have been able to follow up. There are many other cases which have been lost sight of through change of residence, the final results of which we do not know. The mortality is now practically *nil*, but at first we lost three cases through sepsis. This can be avoided, not only by strict asepsis, but by seeing that the scalp is quite healthy, and by having the patients well watched that they do not interfere with the bandages as occurred in two of our cases.

CASE 1.—A boy, a congenital epileptic, aged 11 years, was admitted to the Birkenhead Workhouse Hospital on August 27th, 1902. He had six severe attacks of *grand mal* during the remainder of that year, and eight during the first five months of 1903. These were all diurnal attacks. He was apparently a hopeless imbecile epileptic, unable to talk better than a year old baby; was dull, stupid, and as incapable as an infant of attending to the wants of Nature. The mother had heard of good results in one of my simple trephine cases and brought the child to me for operation. There was evidence that the right arm was first affected by the fit, and in accordance with my ideas on the question of fluid I for the first time, June 4th, 1903, at the Royal Southern Hospital, Liverpool, performed the operation of fenestration of the dura as a complete and predetermined operation. A considerable quantity of clear fluid came away from the pia-arachnoid. The wound healed up by first intention, so that we need not dwell upon details, and the technique of the operation has been already described. On June 7th, 1903, patient had a slight attack. On June 29th he was sent back to the workhouse. Dr. Stansfield, who was present at the operation, and is the medical officer to the Birkenhead Workhouse, informed me that he had one slight fit a week after his return and none since.

In April, 1908, he was admitted to the Epileptic School at Maghull in a much more intelligent state, but still unable to talk, although his vocabulary was somewhat greater. It was hoped that contact with other children would stimulate him to vocal effort. We were here met by a difficulty. The incontinence still continued in much the same state as in hospital, and threatened to bring his school career to an abrupt close. Having overcome the fits we were determined not to be beaten by a secondary difficulty. Fortunately in the adult portion of our colony we had a very steady sensible patient, who told me he had considerable experience in training young animals and loved the work. To him we now deputed the higher task of training in habits of cleanliness an imbecile boy. He undertook the task *con amore*, and in less than three months the boy was able to attend to himself and to keep himself and his bed quite clean. Since the operation the patient has not had a single dose of bromide or any medicine except an occasional dose of aperient medicine. He can talk and play with his companions. He understands what they are saying, and speaks a childish language which they can understand. He can do simple work to which he is put, and there he will stay, doing fairly well till he is taken from it and put to something else, but he cannot do any work that requires thought or change of action. He is obedient, sensitive, and affectionate, and he has now been handed over to the guardians as a cured epileptic. This has been done because he had reached such an age that we could no longer keep him at the school. After eight years we may use the word *cure* in regard to this case.

CASE 2.—The patient was an imbecile boy, aged 15, unable to read, quite intractable, and also subject to frequent epileptic attacks. These were congenital, came on without warning, and probably began on the right side; severe attacks of *grand mal* occurred every few days. The success of the previous case encouraged us in undertaking this one, especially as the parents were very anxious for something to be done. Accordingly, on March 17th, 1904, the operation of fenestration was performed on the left side. The note by the house surgeon is to this effect: "Free incision made through dura mater, meninges in usual œdematous condition, gauze drain inserted. Patient very noisy and restless after, trying to tear bandage off." Up to his discharge on April 11th, 1904, the patient had four fits. Much more frequent before operation. At the end of April, 1907, I followed up the case, and learned from the mother that he went on well after his discharge, had no fits for 12 months, could run errands, attend to directions, and listen to instruction. She was delighted with the gradual improvement, and her hopes were very sanguine in regard to his becoming a useful member of society. At the end of the year, however, his legs began to swell, the eyelids and hands became puffy, and he died from acute Bright's disease on August 5th, 1906. After the dropsy began his fits returned, and continued more or less till he died.

CASE 3.—A boy, aged 3½ years, an imbecile epileptic, was brought to me at the Royal Southern Hospital at the beginning of November, 1905, as a case that might be benefited by operative measures. The boy was reported to be normal till he was 18 months old, and three months after the history of a fall. About that fall we could not obtain any definite information. There was no depression of the skull, and no marks were to be seen. At first he showed "twitching movements" or "partial convulsions." These attacks were easily excited by noises. He had become irritable, cross, and incontinent. The twitchings began in the right hand, and spread rapidly all over the body. When two years old he had scarlet fever, and since that time the attacks became much worse. He had frequent attacks daily. No history of heredity or parental alcoholism. Labour was prolonged, but not instrumental, no natal asphyxia or other cause of imbecility; a very unpromising case, but considering the improvement in Case 4 it was determined to give the boy the chances of the operation although he was a drivelling idiot, unclean and apparently hopeless.

Accordingly in the beginning of December, 1905, the operation was performed successfully, and the patient was discharged from hospital a month after with the wounds healed and the patient as sound in health as before. We were to hear from the mother at intervals as to how he was doing, but we received no information from her for a long time. When at last we unearthed the case we found the mother had been unable to look after the boy; she had handed him over to the guardians, and finally he had been removed to Winwick Asylum, where he was admitted in April, 1907. The medical superintendent, Dr A. Simpson, kindly kept me informed at intervals of the course of the case, and I obtained the following statistics of his attacks when I visited the asylum in 1910: 11 fits in 1907, none in 1908, three in 1910. In a letter, dated April 5th, 1910, Dr. Simpson says, "In reply to your letter of the 4th instant, I beg to inform you that the boy's mental condition is not improving, he becomes more troublesome as he gets older. He has had no fits for three months."

I mention the case to show the improvement in the number of attacks from several thousand annually before operation to 14 fits in three years afterwards. We do not know how many attacks he had under the mother's care after operation.

CASE 4.—A boy, aged 13, was admitted to Royal Southern Hospital from the out patient department on April 23rd, 1906. The boy is said to have fallen on his head in 1903, and to have injured the left side of his head. Some time after this the attacks commenced, and to this fall the disease was ascribed. There was no definite account of the injury, even the time of its occurrence was uncertain, and nothing abnormal was to be seen about the skull or scalp. The attacks were severe and increasing in number, one *grand mal* every week, many attacks at night, mental dulness increasing, and mental faculties becoming perceptibly impaired. On August 1st, 1906, I trephined over the left side of the skull where the injury was supposed to have been, but found the skull entire and normal. The dura was opened, but the quantity of œdema was unusually small. All the steps of fenestration were gone through, and the wound healed *secundum artem*. The effect upon the fits was *nil*, although the mother thought he was brighter.

On June 29th, 1909, she brought him back to me with a report that the night attacks were increasing in number and severity. The day attacks varied, and he had occasional giddy attacks without complete loss of consciousness. "Boy very dull and lethargic, and shows little intelligence." I determined to trephine the right side, although there were no focal symptoms to guide me, but I knew from the previous exploration that the left side of the brain was not the affected side. On July 1st, 1909, I trephined and found the brain œdematous, and at parts the œdema was hæmorrhagic in tint as if there had been an ancient cortical hæmorrhage there at one time. On March 15th, 1910, this patient was admitted to the Epileptic Colony at Maghull. He has become very sensible and intelligent, works very well, and his attacks have become less by one half.

CASE 5.—A boy, aged 11, congenital epileptic, somewhat weak-minded, mental condition that of a child 6 years of age. Having 30 to 40 attacks every six weeks, these coming in batches and producing such prostration and exhaustion as to threaten his life every time. The attacks are all of the *grand mal* type. There is a constant spasmodic tic of right eyelids, especially the right lower lid. During the time the series of attacks are taking place he complains of pains in both legs and over the left acromion process. Both sides of his skull were trephined and fenestrated on Feb. 12th and June 6th, 1907. At the first dressing on June 8th, when the usual small glass drainage-tube was being removed, a large amount of clear fluid had soaked the dressings. Patient looks more intelligent, and says the pain has gone from his legs. He was seen on Sept. 9th, 1907, still free from attacks, healthy, and intelligent. He is being kept under observation. The mother came to me on Jan. 4th, 1911, in great grief. She said the boy had been much better since the operation, but towards the end of the year 1910 he had an attack in which he died. She had been trying to get him into the school at Maghull, but could not succeed. I was very sorry, as a promising case was cut short during an attack, probably through cardiac failure or want of skilled attention during the convulsions.

CASE 6.—A girl, aged 10 years, was sent to me by Dr. Williams, Rock Ferry, as a patient suitable for my fenestration operation, of which he had heard good accounts. She was the subject of attacks of *petit mal*, some of them very slight, but others more severe, entailing frequent falls and injuries. She was simple, could talk about nothing but her fits, and although she looked sharp the appearance was delusive, her mental faculties were much impaired, and judging from the report of the mother the deterioration was evidently progressing. There was no definite aura, but there was a tradition of right-sided twitchings. On Sept. 27th, 1906, I fenestrated the right side, and found the pia-arachnoid "highly œdematous." The wounds healed by first intention, but the attacks were not much influenced, continuing ten daily as before. In consequence I was induced also to operate on the right side, and there I did not find any trace of œdema but considerable tension of the brain, which bulged into the fenestration opening. The wound healed up quite satisfactorily, but during convalescence she had a sharp attack of pneumonia of the base of the left lung which caused some anxiety. It all passed over safely, and she was discharged on Jan. 9th, 1907. I saw her occasionally afterwards. On Oct. 29th, 1910, I received a communication from Dr. Williams asking me to see another case for him, reminding me of this case, which he said I had operated on so successfully, "only 68 fits since last operation, and none since January last, except slight faintings, and these only lasting 'a few seconds.'" He concludes: "I think it is a result you ought to be proud of."

CASE 7.—The patient, aged 10 years, was a school girl who became epileptic at 2½ years of age. The disease gradually increased until she had as many as 16 to 17 fits per diem. Under bromides she had a short respite, but when 5½ years of age her attacks became more severe and more frequent—one every three hours. Left side is chiefly affected. She cries at commencement of an attack, works her arms, especially the left; puts arms over her head. Is feeble-minded and quite uneducated, never having been to school. She was admitted to the Royal Southern Hospital on Feb. 21st, 1910, and was operated upon on Feb. 24th. Usual œdema found and usual operative technique carried out on the right side of the head. On the 26th she had had 15 attacks since operation, but not so severe. The attacks gradually became less, and on April 1st, when discharged, the daily attacks were reduced to none, and during the previous week to two per diem. She is now at the Epileptic School at Maghull, and has only had one attack on an average per week. She is getting on very well at school, is intellectually much brighter, physically better nourished and more energetic, and is a very promising case, in marked contrast to the state of imbecility and irresponsibility which characterised her before operation. Her teacher says: She is rather slow in acquiring knowledge, but when she has grasped it, she holds it firm. Her chances of becoming an intelligent member of society are very good."

CASE 8.—A boy, aged 7 years, admitted to the Royal Southern Hospital on Oct. 7th, 1907, for the purpose of fenestration of the dura. He had been an inmate of the epileptic home at Maghull, since Oct. 13th, 1906, and during the rest of that year, 1906, he had 42 fits.

During 1907 he had 681 attacks, so that his average number was about two daily. He was taking 5 gr. borax and 5 gr. bromide of sodium all the time. The nurse reports: "In going into an attack he begins to stare, the eyes roll backwards, the right side of the face and especially the right angle of the mouth twitch. If he is in a sitting position he does not fall. The whole attack only lasts a few seconds, and he soon recovers his natural condition when the fit is over. His behaviour is silly, his speech is backward and indistinct, and his papers describe him as partially imbecile. He talks all the time and does not listen to what is said to him, except that he pays more attention to his nurse, of whom he is very fond. When an attack is coming on he calls out that he is going to be ill, and falls down if not already seated." The operation was performed on Oct. 10th, 1907. Six large fenestrations were made in the dura mater. The surface of the brain was found to be very œdematous, and bulged through the fenestrations. Wound healed up as usual by first intention. He was discharged on Nov. 30th, having had 81 fits since the operation. During the first part of 1908 he had no medicine whatever, and the number of attacks came down very slowly. He was then placed on the same medicine as before the operation, under which treatment his attacks numbered 681 a year as above recorded. The improvement was now more rapid, and during 1910 he had 38 severe attacks and 18 slight, in all 56, or one per week, a marked contrast to two per day. The boy has developed well physically and intellectually, and has improved in appearance out of all knowledge. The benefit from the operation is so great as to be a surprise to all who have observed the case.

CASE 9.—A boy, aged 7, was admitted to the Royal Southern Hospital on June 2nd, 1908. Twelve months previously he began to have fits, cause unknown. The mother stated that the fits always began with twitchings of left arm. There was no cry and the child had only fallen twice. Loss of consciousness was very short, and the whole attack lasted about half a minute. Child was drowsy for some time afterwards. The attacks occurred irregularly, sometimes four times a day, at other times only once a week. His mental condition was still fairly intelligent, but mind failing, articulation normal. Examination of fundus oculi (Dr. Hamilton): "Veins full and dark (particularly inferior nasal vein); edges of disc woolly." On June 15th fenestration was performed on the right side of the skull, fluid present as usual; wounds healed by first intention. Had one fit on July 11th, none afterwards before his discharge on July 20th, 1910. On July 6th the fundus oculi were again examined by Dr. Hamilton and no change was reported. During 1909 and 1910 the boy has been at the Epileptic School at Maghull, and his attacks have fallen to one per week during these two years, a distinct improvement from what it was before operation, when he had sometimes four attacks per day. He is intelligent and good at his lessons.

CASE 10.—The patient, a boy, aged 15, was admitted to the Royal Southern Hospital on Feb. 16th, 1909, suffering from epilepsy. His attacks had been coming on every fortnight for the past eight years. The attacks were severe, *grand mal*. He knew when the attack was coming on by a feeling in the right hand, and the attack was ushered in by twitchings of the right side of the face and in the right arm. The alleged cause of the disease was scarlet fever, which he had a short time before the attacks began. Patient was fairly intelligent, imperfectly educated, said to be mischievous, mild in temper, and very repentant and submissive when found out in any mischief, and probably tried to be law-abiding, although his impulses were sometimes too strong for him. Medicine had no effect on his attacks, and hence the desire of his friends for operation. On Feb. 17th, 1909, fenestration was performed in the usual way, usual fluid found, and usual good surgical results obtained. No attacks while in hospital. He was received at the Home for Epileptics, Maghull. During the year 1910, when he was under observation at the homes, he has had eight severe and two light attacks. He works steadily and is well conducted. During the last six months he has only had three attacks, one-fourth of what his normal number was before operation.

CASE 11.—A boy, aged 10 years, was admitted to the Royal Southern Hospital on Nov. 2nd, 1909. This child suffered during his first year from pneumonia and meningitis and chicken-pox, and when he was about 12 months old he began to have fits, supposed to be due to the meningitis. The attacks were numerous and short, and mostly affected the right side. The mother said the child appeared to be frightened, and then the right hand and arm began to twitch. The twitchings became more violent and extended to the whole of the right side; left side passive. Did not quite lose consciousness; lasted at most two minutes. He had marks of a flap on left side of his head above the ear, and on inquiry we found that he had been trephined at a children's hospital six years ago, when a thick layer of fluid was found but nothing else, and nothing was done. The opening in the dura was stitched up and the bone replaced. No change had taken place in the attacks. He had since been treated with bromides, iodides, belladonna, diet, removal of teeth and adenoids, without benefit. In 1906 he had 204 attacks; in 1907, 522 attacks; in 1908, 450 attacks; and up to time of operation, Nov. 4th, 1909, he had 368 attacks. Operation of fenestration was performed on Nov. 4th. Extensive œdema, or rather a layer of flocculent fluid, with a thin membrane on surface. This surface membrane was removed and much fluid came away freely. Wound healed in usual way. During convalescence he had 54 slight attacks. The attacks did not diminish during 1910, and in one month, November of that year, he had 800 attacks. At the time of writing his attacks are about one-half of the original number. His mental condition is very much better and he is much less irritable.

CASE 12.—A boy, aged 7, was admitted to the Royal Southern Hospital on Dec. 7th, 1909, suffering from epileptic fits affecting mostly the right side of the body. No heredity; his parents were alive. His grandfather suffered from rheumatism and died from consumption. The fits began two years ago, and averaged about 24 per month, or about one daily. Right arm and leg work especially. Was quite unconscious and cyanosed during attack. On Dec. 9th, 1909, I trephined, and the dura mater was fenestrated on the left side; œdema on the surface of the convolutions. Wounds healed by first intention. No attacks while in hospital. He then went home for some time, and was admitted to the school at Maghull. Attacks much reduced; now average ten per month, a reduction of nearly two-thirds. Mental and physical condition much improved.

CASE 13.—A male, aged 30, was admitted to the Royal Southern Hospital on April 1st, 1908. He had suffered from epilepsy for the past 16 months. Twenty-two months ago patient was working under an iron girder. He suddenly stood up and struck the back of his head. He was senseless for about half an hour. He noticed nothing further and received no treatment. About 16 months ago he began to develop fits every six weeks. The fits are confined to the right side. He always has a left-sided headache, shooting from front to back, before fits. He loses consciousness instantly. The fits (*grand mal*) have gradually increased, especially since he was operated on in a country hospital, coming now every week instead of every six weeks. Medicine does not seem to have any control over number or severity. Knee-jerks exaggerated, slight ankle clonus on both sides. No paresis anywhere; eyes normal. No marks on skull except that of trephining a little below vertex on right side. Operation April 2nd, 1908. Fenestration performed in the usual place above parietal eminence. The brain was much congested and the œdema was considerable. The wounds healed as usual by first intention, and the patient left hospital on May 2nd, 1908, having had six fits during his convalescence. On June 6th, 1909, the patient's wife wrote: "In answer to your kind letter, I am pleased to say my husband has much improved. He is heavy at times and has to lie down, and the few attacks that he has are slighter than they were before operation."

CASE 14.—A man, aged 42, admitted to the Royal Southern Hospital on Nov. 26th, 1907. Ten years ago patient was wheeling a hand cart containing two machines, when he slipped and fell against a kerbstone. He had to let go the hand-cart and the two machines fell on his head and body. He was bruised and rendered unconscious, and taken to a hospital, which he attended for some time afterwards as an out-patient. A fortnight later he had a fit in the street, in which he was incontinent and bit his tongue. Lately he has had one or two attacks a fortnight. No sensory aura. His father had died from phthisis, aged 39, and his mother from pneumonia, aged 58. Three sisters were living, and a brother and sister had died in infancy. The patient worked at odd jobs, was of steady habits, and had had no venereal disease. There was a slight depression of the skull above the superior curved line on the right side, but it was doubtful whether it was traumatic in origin. Patient mentally a little simple. Reflexes also muscular, and sensory functions normal on both sides. Vision of eyes normal. No indication for operation except the depression. Nov. 28th, 1907: Fenestration operation performed on the right so as to take in the depression on the skull; no signs of injury to the bone. The bone was very soft and vascular. There was a localised patch of œdema at the lower part of the opening in the skull; elsewhere the brain looked healthy. The wound healed by first intention. Fits during convalescence, 62. At the end of December it was manifest that no impression had been made on the disease, and that we had been deceived by the depression, and had opened the wrong side of the brain. With the approbation of the patient and his friends we operated on Jan. 2nd, 1908, on the opposite side. Here the surface of the brain was very œdematous—a contrast to the same parts of the opposite side at the previous operation. The wound healed as usual. Fits after operation, 40. Discharged Jan. 31st, 1908. It was noticed by the house surgeon that the patient was much brighter, and cerebration was much quicker after the second operation. He was sent to the Colony at Maghull, where his attacks became much less frequent, but he was erratic and difficult to control. He ran away, and was for a time in the workhouse wards in Liverpool. Here he had no attacks for two months. He left that place and was found at West Derby workhouse; his attacks were kindly reported to me by the resident, Mr. O. H. Williams, for a month. No attacks in the day, and 20 at night during that time. The case was a promising one, had it not been for the unmanageable and erratic character of the patient. On the whole he had improved, but being restless he did not carry out any treatment and went from one institution to another as the impulse took him.

CASE 15.—A schoolgirl, aged 11 years, admitted to the Royal Southern Hospital July 16th, 1907. Her parents, brothers, and sisters were all alive. No evidence of heredity. Six months previously to the first fit, four years ago, she had a fright by a dog, which jumped up on her. When 8 years old a chimney-pot fell on her head, but this was not evidently the cause of the disease which had appeared a year previously. The month before admission she had two series of attacks. She had been at school before she was taken ill, and could read and write. Occasionally she was obstinate and difficult to manage, would shut herself up in a room, locking the door behind, and would not open it and the door had to be forced. Her father could control her but not any of the rest of the family. The attacks occurred in batches, but sometimes would continue for 13 hours, but generally they lasted eight hours. The left arm and leg were the first convulsed. Fenestration performed July 17th. There was considerable œdema along the vessels, especially posteriorly. Drained as usual. Healed by first intention. Had one fit on August 4th, no more while in hospital. She was at the epileptic school at Maghull during all 1910. She had only had one mental equivalent, early in that year, when she was obstinate and difficult. She had had one and sometimes two attacks per month, but these were all single, and passed away quickly. She was intelligent, clean, and tidy, and earned good reports, and tried hard to do her best to be agreeable.

CASE 16.—A girl, aged 10, of rather low extraction, and the subject for some time of granular lids, now cured. She had been epileptic for two years past; no heredity discoverable. The attacks average four to five every night, and were apparently unaffected by medicine. The twitching mostly affected the right side. Face said to be drawn to the left. The child was operated upon in the workhouse hospital on June 22nd, 1910, in the usual way. During the first 24 hours there were 12 attacks; most of these were slight and of short duration. Next day 12 attacks, next day 11 attacks, next day 10 attacks. The fits continued for two weeks, becoming gradually fewer in number and less severe, and for a time before discharge she did not have any. No medicine administered. She was discharged from the surgical department on August 16th. She remained in another department of the workhouse hospital till the end of November, 1910, when she was transferred to the Epileptic School at Maghull, not having had an attack since August 9th. On June 19th, 1911, she was still without attacks and did not require any medicine.

CASE 17.—A girl, aged 13, was admitted to the Liverpool workhouse hospital in 1910. She had been subject to epileptic fits for the last nine months, the cause being unknown except that she had a fall on the forehead nine years ago. No evidence of heredity. Attacks usually occurred during the night. Twitching chiefly on the left side, the mouth being drawn to the left and the head turned to the left. Slept for some time after an attack. Average number, three or four daily. On May 11th fenestration was performed. Œdema distinct, but not so

much as is generally found. On the first day after operation she had eight fits, on the second day five, third day two, then none for a week. On the 22nd one fit, 23rd one fit, none after that, and no medicine until the middle of November when she had severe slight attacks. She was put on borax and sodium bromide, and the attacks immediately disappeared. She is now at the Epileptic School at Maghull.

CASE 18.—A man, aged 35, admitted to the Royal Southern Hospital on March 1st, 1910, suffering from right hemiplegia, aphasia, and fits. He was a very precocious child, being able to speak and even, it is said, to converse when ten months old. When about two years old he had some fits and aphasia and lost the power of walking. He slowly recovered, and was educated and able to do clerical work till two years ago. He then become epileptic, aphasic, and right hemiplegic, in which condition he was received into the Royal Southern Hospital under my care. There was no record of syphilis, but previous to operation he had taken iodide of potassium in large doses for some weeks without any effect. On March 3rd fenestration was performed, and a wide area of dura mater exposed. "The dura mater bulged and the vessels were distended and stood out in thick lines. The dura mater was incised, when the arachnoid bulged through the opening, presenting a picture as of several 'cysts' filled with clear translucent fluid with little white spots dotted in their walls." The arachnoid was opened where it bulged through the dura, and a very large quantity of clear fluid escaped. Convolutions seemed smaller, and a finger could be inserted between them and the bone. No disease except collection of fluid. Drainage as usual. In 48 hours the drainage-tube was removed and the dressings found saturated with fluid. The wound healed satisfactorily, the aphasia remained, but the paralysis and fits disappeared. He was seen on March 1st, 1911; he had had one fit since discharge and is back at work. Hemiplegia quite gone and speech returning slowly.

CASE 19.—The patient was a boy, aged 11. Father killed by accident. A mother, two sisters, and a brother were alive and well. The habits of the parents unknown and no history of heredity. The boy fell off a wagon four years ago and was said to have hurt his head, but nothing definite known as to part injured and no evidence of injury to skull now to be seen. Three or four years ago he commenced having fits, having three to four daily since. Bromides had had very little apparent effect, and hence request for operation. He was admitted to the Liverpool workhouse hospital on Sept. 29th, 1909. The fits always began on the right side, especially the right arm, which became stiff. After fit was over he was often found to be doubly incontinent, and was heavy, stupid, or dazed for an hour or more. The week before operation he had 38 fits. On Oct. 22nd, 1909, the left motor area was fenestrated, the usual fluid drained away, and wound healed with the usual aseptic result. On Dec. 10th, 1910, it was noted that the child after operation was much better in health. The incontinence had disappeared and his mental condition was much brighter. Several days now intervened between attacks, and these were now rarely severe. He was sent to the Epileptic School at Maghull. The fits are now much less, one-tenth of what they were before operation. His mind is clear.

CASE 20.—The patient was a boy aged 5 years. His parents were alive. No history was obtainable about their habits or about any hereditary tendencies. A grandmother suffered from rheumatism. Epilepsy ascribed to a fall in the street, but no visible effects produced and the time of the fall unknown. He had his first fit on August 8th, 1908. Has had three to four fits daily. Patient uttered an unintelligible sound, the right arm was held out stiff, the fingers working violently, then the right leg became affected. There was some paralysis of the right side of the body. The child was intelligent, but of course entirely uneducated. He was admitted to the Royal Southern Hospital on Oct. 22nd, 1909, and operated upon two days after. The usual fenestration was performed over the left motor area, with the usual satisfactory surgical results. He was then taken home by the mother, and finally received into the Epileptic School at Maghull on April 29th, 1910. On June 26th, 1911, he was still at Maghull. He has had no fits and no medicine since operation.

Such are the brief records up to date of 20 cases that have been operated on by a definite operation; most of the patients have been under observation and have had rational treatment afterwards. There are other patients whom I have seen occasionally but not lately who were promising well, but the treatment I recommended could not be carried out and they fell again into the hands of quacks who took all the credit that was going for any improvement. Nevertheless, in every case some benefit was observed, and probably much more would have accrued had wise counsels prevailed. My experience shows that the results in children are more uniform and more permanently successful. In adults the benefit is the more permanent the larger the opening, but in these the influence of the operation becomes weakened as the scar becomes hard and tense. In all intractable cases in young life the operation can be strongly recommended. For instance, in Case 11 medicines were useless, and the attacks were nearly two a day under approved hygiene and medical treatment. After operation medicine has a more distinct and definite ameliorative result, and the gradual improvement in this respect due to the operation was undoubted.

I am quite familiar with the theory, that will again be revived on reading this paper, that the mental effects of an operation on epileptics may account for any improvement. The mental impression cannot be produced on imbecile epileptics, however, although it might have some effect on the disease in some intelligent adults. My first cases did not know they were epileptics, did not know they were operated upon or that they had any need of relief. And none of the more rational children had really any better knowledge. I think the good results may be ascribed fairly to the removal of the fluid and to the facilities for its absorption afterwards. The improvement in the mental condition of the patients has been very marked and has been spontaneously observed by nurses, house surgeons, and relatives.

If, as I hope, in the future the treatment of epilepsy should be taken in hand in a rational, systematic, and determined way, the operation will be available for a certain number of intractable cases at a sufficiently early stage when good results may be expected from it, and when the patient can be retained under good hygienic and medical control until the conditions of the brain have become such that the fits will disappear. In many cases of epilepsy no operation is necessary, and in others the necessary aura may be absent, and in such it would be difficult to find the part of the brain where the fluid is to be found. I believe, however, in the work detailed in this paper we have some hope of relief when other measures have failed, and that we have also a clue to another theory of epilepsy that may prove of more practical benefit than that which holds the field at the present time. Of that more anon.

Conclusions.

1. There are some cases of epilepsy that prove intractable to general medical and hygienic treatment, and these, unless the disease be somehow arrested, will soon terminate in imbecility and death.

2. In these cases the affected motor area is covered by more or less œdema of the pia-arachnoid, and this œdema probably so affects the cells of the cortex as to predispose to, or cause, the epilepsy and imbecility.

3. In cases with localising aura, we can, by the operation of fenestration of the dura mater, drain these œdematous areas and prevent re-accumulations.

4. By the operation the progress of the disease has always been retarded. In several the fits have stopped, and in many have been reduced to fractions of the original number.

Liverpool.

THE VIABILITY OF HUMAN CARCINOMA IN ANIMALS.[1]

BY C. L. WILLIAMS, M.D. EDIN., M.R.C.S. ENG.,
MAJOR, I.M.S. (RET.).

(From the Cancer Research Laboratory, University of Liverpool—Mrs. Sutton Timmis Memorial.)

THE object of the present research is to determine the cell changes occurring in portions of human carcinoma implanted into animals, and more particularly to ascertain if such implanted tissues are capable of surviving for a time, and if so, the manner in which they succumb.

Implantation of human carcinoma into animals has been made by numerous observers, and the failure of such implantations to produce tumours is now an ascertained fact. Among the earliest experiments are those of Ballance and Shattock,[2] the objective of which was to determine if human carcinoma was transferable from man to animals; in these observations the immediate effect of implantation upon the cells of the growth was not determined. Von Langenbeck,[3] Jürgens,[4] Dagonet and Mauclaire,[5] and Gaylord[6] produced in animals, by inoculation of carcinoma, tumours which, however, differed in structure from the original. Lewin[7] succeeded in obtaining inoculable granulomata in dogs by implantation of a human ovarian carcinoma, and also in rats by inoculation of a carcinoma of the cervix of the human uterus; this author made numerous attempts to obtain inoculable tissues by implantation of human carcinoma, but only the above two were successful.

[7] Ueber Versuche, durch Uebertragung von Menschlichen Krebsmaterial verimpfbare Geschwülste bei Tieren zu erzeugen.

The effect of implantation of mouse carcinoma and sarcoma into rats has been studied by Ehrlich,[8] who found that during the first 8–10 days after inoculation the rate of growth was scarcely less than before implantation; at the end of this period, however, growth ceased and gradual absorption occurred.

The method adopted in this research was that of implanting subcutaneously, with aseptic precautions, several selected portions of a malignant growth, freshly excised (pieces being put aside for microscopical observation), and following up the changes taking place in the cells of the growth by reference to sections of the implanted masses, removed for examination at different periods. The time elapsing between separation from the human body and the completion of implantation varied between 20 and 25 minutes. Implantation was effected by puncturing the skin with a straight cataract knife, and introducing on the point of the knife a piece of tissue having the form of a cube of 1 to 1½ mm. The portions of tumour implanted were removed at intervals of 1 to 13 days.

The number of tumours used for implantation was 41; 10 tumours were, however, employed in connexion with unsuccessful implantations, so that only 31 need be referred to here. Of these, 19 were epithelioma (17 primary growths, 2 secondarily infected glands), 10 were scirrhus of the breast (9 primary growths, 1 secondarily infected gland), 1 was spheroidal-celled carcinoma, and 1 rodent ulcer. Implantation was made upon the monkey (20 tumours), rabbit (4 tumours), pigeon and guinea-pig (each 2 tumours), cat, rat, and mouse (each 1 tumour).

The usual causes of unsuccessful experiments were suppuration and failure to recover the pieces of tumour implanted. Suppuration was not met with so frequently as was expected, even in the case of growths ulcerated on the surface; when present sometimes every piece of a tumour used for implantation became the seat of suppuration, in other cases suppuration occurred at some of the sites of implantation, while at others no inflammatory reaction occurred. A more serious difficulty was failure to recover the portion of tumour implanted. In a small number of cases this arose from the piece of tissue lying near the opening in the skin by which it was introduced, and in consequence desiccation ensuing. In other cases the piece of tumour implanted appeared to have moved from its original position and could not be traced. Not infrequently the portion of growth implanted seemed to have undergone very rapid absorption, with the result that either the piece of tumour implanted could not be traced or no unmistakable growth of the original mass could be recognised in what is regarded as the remains of the implanted mass; difficulties of this kind were common from the fifth day after implantation onwards, and thus tend to limit the number of observations possible at later periods.

The result of implantation is summarised in the table

Implantation of Human Carcinoma. The + and − signs indicate the presence and absence respectively of living cells (L) *and mitoses* (M).

No. of experiment.	Tumour.	Animal used for implantation.	Condition of implanted portions of growth at end of— 1 day. L	1 day. M	2 days. L	2 days. M	3 days. L	3 days. M	4 days. L	4 days. M	5 days. [8] Beiträge zur Experimentellen Pathologie und Chemotherapie. Leipzig, 1909, p. 135.

The usual course of events occurring after implantation was as follows: In naked-eye aspect the tumour, which was usually easily recognisable, being moist and greyish in aspect and lying loosely among the tissues of the host, did not appear much changed during the first two days. After this period it became dry and increasingly adherent to the surrounding tissues, from which it was less readily distinguished after the fifth day. On microscopic examination the central portions of the growth were found to have undergone necrosis during the first two to three days, presumably in part, at any rate, owing to defective supply of oxygen. Some of the cells at the periphery of the implanted mass, on the other hand, at first remained unchanged in appearance and exhibited more or less evidence of proliferation, generally presenting for the first two to four days mitoses, though fewer in number than was exhibited by the growth before implantation. After the fifth day all the cells of the implanted tumour had become altered and ceased to exhibit mitoses; their nuclear chromatin no longer presented the usual arrangement, but had become collected into irregular masses or fragments. Accompanying the necrotic changes occurring in the portions of tissue implanted, leucocytes, mostly polynuclear, made their appearance in large numbers, being replaced subsequently by mononuclear cells before which the remains of the implanted tissue disappeared. The disappearance of a piece of tumour of the form of a millimetre cube appeared to be completed after the second week of implantation.

In the summary given in the table the proportion of observations in which living cells and mitoses were noted during the first five days after implantation is given in a percentage form. It will be seen that inhibition of the function of cell division is early marked, while cell death occurs (at the periphery of the implanted mass) more slowly. If the experiments made upon the monkey alone are considered, the percentages obtained are more regular, being respectively 67 and 25 on the first day, 69 and 8 on the second day, 67 and 0 on the third day, 37 and 12 on the fourth day, and 20 and 20 on the fifth day. The experiments made with animals other than the monkey are too few in number to yield percentage values, but the circumstance that mitoses were not met with after implantation suggests that human carcinoma is less viable in these animals than in the monkey.

The result of implanting human carcinoma upon animals, it will be observed, is similar to that of implanting mouse carcinoma upon rats already referred to. In both cases a limited degree of inoculability is observable, some of the implanted cells continuing for a time to live and to divide, but whereas in the latter case the rate of proliferation is at first little affected and regression does not begin till the eighth to the tenth day, in the present experiments the cells of the implanted portions of tumour ceased to proliferate at an earlier period, and were no longer living after the expiration of five days.

In conclusion I must express my indebtedness to Dr. Wakelin Barratt for the assistance he has given throughout the course of this work.

Summary.—1. Portions of human carcinoma implanted into animals were observed during the first five days to retain their vitality and to exhibit mitosis after implantation. 2. After the expiration of this period no evidence of vitality was observed. 3. Mitosis was markedly inhibited within 24 hours of implantation, whilst the life of the implanted cells was abolished less rapidly.

Birkenhead.

MEDICO-PSYCHOLOGICAL ASSOCIATION. — The autumn meeting of the South-Eastern Division of this association will be held, by the courtesy of Dr. Hugh Kerr, at the Bucks County Asylum, Stone, Aylesbury, on Wednesday, Oct. 4th. After the transaction of formal business, Dr. John Turner will read a paper on A Classification of Insanity, and Dr. J. F. Corson one on Insane Heredity in the Insane of a Rural Population. Dr. Kerr has invited the members to luncheon at the Bucks County Asylum, and they will dine together, after the meeting, at the Café Monico, Piccadilly-circus, W., at 6.45 P.M., provided that a sufficient number agree to dine. Communications concerning the dinner (5*s.*, exclusive of wine; morning dress) should be made to Dr. David Hunter at the West Ham Borough Asylum, Goodmayes, Essex.

AN

EXPERIMENTAL COMPARISON BETWEEN "606," MERCURY, AND IODIDE OF POTASSIUM AS ANTISYPHILITICS.

BY JAMES McINTOSH, M.D. ABERD.,
GROCERS' RESEARCH SCHOLAR;
AND
PAUL FILDES, M.B., B.C. CANTAB,
ASSISTANT BACTERIOLOGIST TO THE LONDON HOSPITAL.

(*From the Bacteriological Laboratory of the London Hospital*—DR. WILLIAM BULLOCH.)

EXPERIMENTAL investigations in syphilis have become more general since the demonstration by Tomaszewski of the possibility of a testicular infection in the rabbit. This animal is more suitable than monkeys on the score of expense, and, further, the lesions are well localised for observation and are very rich in spirochætæ. Positive inoculations are readily obtained on the skin of the scrotum or deeply into the testis. Some disadvantage is, however, to be found in the fact that in the rabbit the disease is practically local and liable to spontaneous cure. No generalised symptoms are observed, although the virus is demonstrable in the internal organs by means of inoculations of these organs into other animals. The antisyphilitic effect of mercuric chloride has been studied on the rabbit by Tomaszewski, and mercuric atoxyl by Uhlenhuth and Manteufel. Hata also worked largely on this animal when determining the value of "606." We have investigated the antisyphilitic power of "606," mercury, and potassium iodide.

1. *Dioxydiamidoarsenobenzol* ("*606*").

6/12/10.—Rabbit No. 4 was inoculated on both testicles with the virus obtained from a chancre on another rabbit. 10/1/11.—An indurated nodule was detected in the skin of the scrotum on the left side. 16/1/11.—A small nodule was found on the right testicle, that on the left was larger and contained many spirochætæ. 20/1/11.—Ulceration started in the left-hand lesion. 31/1/11.—The ulcer was larger, measuring 2 × 1·5 cm., its edges were indurated and rolled (Fig. 1). On this day the animal (2975 grm.) was injected intravenously at 12 A.M. with 0·1 grm. of "606" in 40 c.c. of fluid. Following the injection its temperature rose 4° F. in 3½ hours. Six hours after the injection, however, the temperature was again normal. No symptoms of general disturbance were observed.

The *effect on the spirochætæ* was followed by means of the method of dark-ground illumination.

At 12 A.M. (the time of inoculation): Numerous spirochætæ were found in every field in a state of unusual motility. 1 P.M.: No change. 1.30 P.M.: No change. Spirochætæ perhaps less active. 2.30 P.M.: Spirochætæ certainly less motile. 3 P.M.: No further change. 3.30 P.M.: Spirochætæ fewer in number, and some were observed to be immobile. 4.30 P.M.: Number of spirochætæ much less. 5 P.M.: Only a few motile organisms seen, the rest motionless and fragmented. 6 P.M.: Only two intact but immobile spirochætæ seen. 6.30 P.M.: A few fragments only observed.

The destruction of the spirochætæ, therefore, began about three hours after the injection and reached its maximum four or five hours after. The effect was complete in seven hours. In man we have found the corresponding figure to be nine hours after adequate treatment.

The effect on the lesion exerted by this injection was very striking. Within two hours it appeared that the pain had disappeared, since the animal no longer winced under the frequent examinations. In six hours the ulcer had shrunk so much that the scab appeared relatively too large. Fig. 1 shows the lesion before treatment (31/1/11):—

1/2/11.—Chancre much smaller. No spirochætæ found. 2/2/11.—Continued diminution. The scab was detached all round its circumference. 6/2/11.—The scab fell off. 8/2/11.—The lesion as in Fig. 2. 13/2/11.—The ulcer still smaller. 16/2/11.—Completely healed, as in Fig. 3.

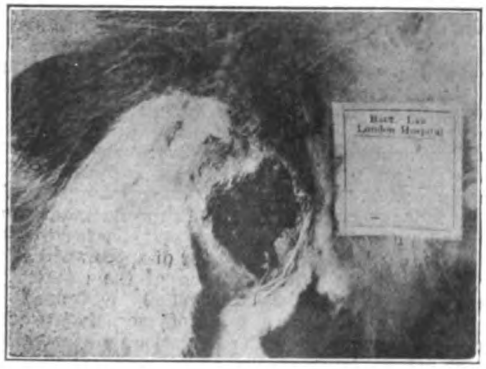
During the process of healing described above chancres on control rabbits remained unaltered. In the course of eight weeks the Wassermann reaction showed a marked quantitative diminution in strength. Owing to a frequent occurrence of this reaction in normal rabbits the final result may perhaps be taken as negative, but these effects should be looked upon with reserve.

2 *Mercury*.—Since it was required to obtain the maximum effect the injection was given intravenously in the form of biniodide, this salt being most suited for the purpose.

14/12/10.—Rabbit No. 7 was inoculated in both testicles with the virus from another rabbit. 17/1/11.—A hard nodule was found in the

left testicle containing many spirochætæ. 20/1/11.—The chancre was much larger and already ulcerating. 10/2/11.—The chancre measured 1·5 cm. in diameter; it was covered with a thick crust, but there was no induration of its edges. (Fig. 4.) At 12 A.M. on this day 0·005 grm. of biniodide of mercury was injected intravenously in 20 c.c. of saline. The highest temperature 103° F. (normal about 101° F.) was noted six hours after the injection. Next day the temperature was normal. No ill-effects were observed other than thrombosis and subsequent gangrene of a small section of the ear. Three days later (13/2/11) a further intravenous injection of 0·008 grm. of biniodide was given.

FIG. 1.



The lesion before treatment.

FIG. 2.

The lesion a fortnight later.

The *effect on the spirochætæ* was found to be much less after these two injections than after the injection of "606." No alteration was found 24 hours after the first injection, while even four days after a few spirochætæ were found. On the fifth day, however, no organisms were detectable.

The *effect on the lesion* was as follows:—

10/2/11.—Date of first inection. Chancre as in Fig. 4. 11/2/11.—No change. 13/2/11.—No change. Second injection. 14/2/11.—Chancre slightly smaller. 20/2/11.—Considerably smaller. Scab still *in situ*. 24/2/11.—Lesion much smaller. Scab dropped off. Fig. 5. 6/3/11.—Chancre quite healed.

FIG. 3.

Testicular syphilis in the rabbit. Effect of injection of 0·1 grm. of "606."

"606" represented one-sixth of an adult human dose, while the amount of mercury represented three adult human doses.

3. *Potassium iodide.*—**According to Neisser this salt has direct spirochæticidal powers. Tomasczewski, however, is of the opposite opinion; he nevertheless considers that iodide is capable of enhancing the therapeutic effect of mercury.**

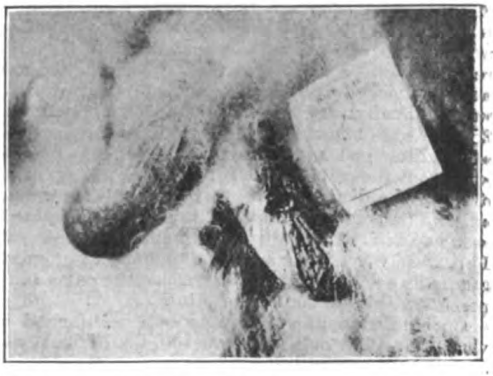
6/4/11.—Rabbit No. 18 was inoculated in both testicles with virus from another animal. 18/5/11.—A nodule was found in the skin over the right testicle. 16/6/11.—The nodule was now the size of a pea. 0·2 gramme of potassium iodide in 20 c.c. of saline was injected intravenously on five different occasions at intervals of two days. No general disturbance was observed.

No *effect on the spirochætæ* was observed and no *alteration in the size of the lesion.*

Conclusions.—**1. "606" in experimental syphilis of the rabbit possesses spirochæticidal properties much in advance of mercury. 2. Potassium iodide is not a direct antisyphilitic.**

FIG. 4.

FIG. 5.



Testicular syphilis in the rabbit. Effect of injection of 0·013 grm. of biniodide of mercury.

In the control rabbits no alteration occurred. The Wassermann reaction of the animal in this case was negative throughout the experiment.

As a comparison between these effects obtained by "606" and mercury it may be roughly assumed that the amount of

A CASE OF INTUSSUSCEPTION OF THE APPENDIX VERMIFORMIS IN AN ADULT,

WITH A PATHOLOGICAL REPORT AND AN EXPLANATION.

BY JOHN H. WATSON, M.B., B.S. LOND., F.R.C.S. ENG.,

HONORARY MEDICAL OFFICER, VICTORIA HOSPITAL, BURNLEY.

IN recording this case as one of intussusception of the appendix I have been guided by Kelly's[1] classification and regard it as conforming to his second group—that is, one in which the base of the appendix forms the apex of the intussusception. The complete inversion of the appendix is, and must be, in the adult on anatomical grounds a curiosity of extreme rarity. Battle and Corner[2] have discovered reports of 29 cases, most of which they say "were complete and there was no scrap of evidence to show its pathogenesis." They further state that all these cases except one occurred at an age before that at which appendicitis is common, and in no case was there any history of earlier inflammation of that organ. Kelly's findings are similar; he has analysed 20 cases, 19 of which were in children, the average age being 4 years and 8 months, and one only in an adult who was 40 years of age, but of this last there are no details. The present case appears to me of more than usual interest because, first, contrary to expectation, the intussusception occurred at an age when appendicitis is most common; secondly, an attack of appendicitis was a predisposing cause; and thirdly, intussusceptions in the adult are still a rarity (though Codman was able to collect 29 cases of intussusception at the Massachusetts General Hospital between the years 1898 and 1908, 9 of which were in adults). Their consideration has not received anything like the care devoted to similar lesions in children. It will therefore serve as a reminder that such cases do arise; that they are difficult of diagnosis and require prompt surgical treatment, for delay can only increase the surgical risks and may even render such assistance futile, the patient dying during a period of masterful inactivity.

The patient in the case here recorded was a male, aged 18 years, by occupation a weaver. Up to the time of his illness he had always been healthy. On Jan. 11th, 1911, in the afternoon, whilst lifting a heavy beam, he felt a sudden pain in the pit of his stomach, which caused him to stop at once, and it was so intense that he was not able to resume for some time. During the night the pain continued, but on the following morning it was not bad enough to stop him going back to work. On the morning of the 13th the pain became much more severe, and was noticed now more in his right side, and he was sick on several occasions. Under the impression that he had "strained his inside" he went to see Dr. W. J. D. Bromley of Padiham, who sent him to bed, considering him to be suffering from appendicitis, and treated him accordingly. Here the patient remained until a week later, when, feeling better on the 20th, he once more resumed his occupation. However, it was with difficulty that he managed to do his work, and on the 25th he was obliged to give up on account of several attacks of vomiting and severe pains of a griping character felt at and about the umbilicus. Dr. Bromley was again called and discovered a distinct lump, very evident when the pains were on, and peristaltic contractions of the bowels could also be seen and felt. The patient was kept under observation until Feb. 24th, when, as he appeared to make no progress but was gradually getting thinner and weaker, the pains and vomiting persisting, he was sent to hospital.

On admission he was seen to be a well-formed youth but very thin. The pulse-rate was 100, the respirations were 24, and the temperature was 98·6° F. On examining the abdomen there was no marked distension, but although the abdominal wall was for the most part soft, there was some slight resistance in the lower part and tenderness on deep palpation below and to the left of the umbilicus. No lump was then felt, but as a result of our manipulations a pain came on accompanied by considerable rumbling and gurgling noises in the bowel, and the rapid appearance of a lump below and to the left of the umbilicus. The cramp-like pain made the patient groan, and to obtain relief he drew up his legs, doubling in a similar way to a person suffering from severe colic. As the cramp diminished the tumour felt less hard, altering its position, and with complete cessation of the pain was lost. On examination of the rectum no tumour was felt, but there was very marked ballooning, and the rectum and anus were exquisitely tender. The patient was kept under observation for six days, and during this time the house surgeon, Dr. D. J. McLaren, verified the previous findings on several occasions. The paroxysmal pains were noted to be more frequent after meals—in fact, he was afraid to eat a good meal—their intensity varying from day to day. The more severe pains were relieved by the administration of morphine. During this time his diet for the most part was liquid—beef-tea, diluted milk, and panopeptone. There was now no vomiting. He passed wind freely by the anus and had daily two or three small loose motions containing some mucus but no blood.

It was evident that the patient was suffering from a chronic obstruction, the site being, in our opinion, the pelvic colon; as to its exact nature we could not be more definite than suggest a new growth. Intussusception was mentioned but put aside, partly on account of the disappearance of the tumour, its rarity, and the condition of the stools. An exploratory laparotomy was therefore performed on March 2nd. A quarter of a grain of morphia was given half an hour previously to the operation, the anæsthetic being chloroform followed by ether. An incision was made in the mid-line below the umbilicus, and on inserting the hand into the wound an elastic tumour was felt almost in the mid-line extending upwards a considerable distance out of the pelvis. The wound was rapidly enlarged above the umbilicus and a huge intussusception thus exposed taking the form of a compressed U, involving the greater part of the colon, the proximal limb having a semi-solid elastic consistency, the distal portion being empty, stretched, congested, and at the same time thickened colon turning up towards the splenic flexure. An attempt was now made to reduce the intussusception by manipulation, and we succeeded after much trouble and loss of valuable time in unravelling all except 4 inches about the ileo-cæcal junction. The colon unravelled in this manner was found to have an unusually long and thickened mesentery—in fact, all the parts involved were so very much swollen, congested, and ragged from tearing adhesions during the separation of the parts that I determined to resect the whole of the damaged part, in all about 4 ft. 2 in., comprising 2 ft. 3 in. of small bowel and 1 ft. 11 in. of large. The divided ends were then closed and a lateral anastomosis was made between the ileum and the pelvic colon. The wound was sewn up in layers, and the patient returned to the ward just under two hours from the beginning of the anæsthetic. He received about three-quarters of a grain of morphia during the first 48 hours after the operation for the purpose of diminishing peristaltic movement of the bowel. His recovery was rapid, without any complications, and excellent in every way. His bowels moved naturally on the fourth day. He left hospital on March 26th, and he is now able to follow his usual occupation.

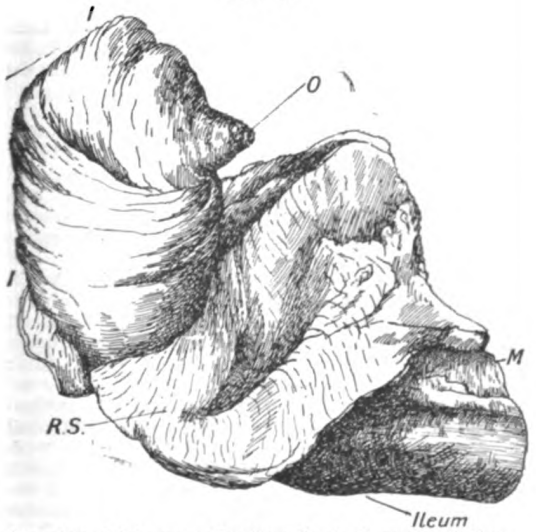
Pathological Report.

On cutting open the resected gut the apex of the intussusception was found to taper off on its internal lateral aspect in a marked conical projection overhanging the ileo-cæcal valve, but not blocking it, having a central aperture which admits a fine probe a distance of about half an inch. I concluded at first that this must be a partial inversion of the appendix. The actual condition is well shown in Figs. 1 and 2, views respectively from the anterior and internal lateral aspects of the specimen. A coronal section (Fig. 3) was made, fortunately bisecting the appendix and showing its relation to the small and large bowel. The specially striking features relating to the appendix are thus seen to be: (1) the occlusion of the lumen with the exception of a cystic space at the tip; (2) the mucosa is more or less destroyed and replaced by fibrous tissue which similarly fills in the lumen; (3) a prolapse or pouting of the mucous membrane at the base forms the conical projection into the colon already mentioned, and contains what remains of the appendical canal—there is just a suspicion of a partial inversion of the muscular coat also at the inner angle of this basal part; and (4) dimensions of appendix—length 3½ in., of which ¾ in. inverted, greatest

diameter ⅜ in., narrowest diameter ¼ in., distance between orifice of appendix and ileo-cæcal valve ⅜ in. One other point of importance is shown—namely, that the peritoneum has been stripped away from the caput coli and has become adherent to the appendix, the intervening space being filled in with a honeycombed arrangement of fibrous tissue, the meshes of which are occupied by a dark brown substance, apparently organising blood clot.

The above pathological data are most interesting, in that they give the clue to the origin and sequence of events described in this youth's case. From the thickened fibrotic and cystic condition of the appendix one may surmise that a previous subacute inflammatory state was actually in process when he strained himself on Jan. 11th. The condition then became suddenly intensified, giving rise to the severe pain at the pit of the stomach, which I regard as his first symptom—that is, an acute attack provoked in a chronically diseased appendix. The actual cause of the sudden pain can be ascribed to the trauma of the violent muscular exertion whilst lifting, which in itself is an acknowledged cause of appendicitis, possibly causing destruction of adhesions by pressure or compression, and thus a fresh involvement of the peritoneum (Lennander) or stimulating a spasm of the muscular wall of the appendix leading to referred pain (J. Mackenzie).

FIG. 1.



Drawing of intussusception from front, shown by slitting below along anterior longitudinal band. I.I, Intussusceptum, mucous lining of inverted cæcum and colon exposed. R.S., Reflected sheath, inner aspect. M, Mesentery. O, Orifice of appendix.

As the cyst was at the tip and well shut off from the root of the appendix by intervening fibrous tissue the most likely site left for a fresh inflammatory outbreak would be the base where the mucosa is still existent. The result of the reaction consequent upon an increased exudation would be swelling of the mucosa towards the lumen of the cæcum. The base of the appendix, being already in a fibrotic condition, would block further exudation in that direction, and thus we have produced the cone-shaped projection which is practically the origin of the so-called inversion of the appendix.

But there is more to explain. The appendix on one side has become adherent to the caput coli, presumably from an extension of the inflammatory process from the interior of the base of the appendix to the adjacent peritoneal coverings. This should tend still further to bulge in the cæcal wall and intensify the inversive movement. Again, as a consequence of more violent muscular contractions, the peritoneal coat of the cæcum, which is now glued to the appendix, has separated and a hæmatoma formed, thus creating a large polypoid mass protruding into the colon above the ileo-cæcal valve. In this manner there is produced a pedunculated tumour in the colon.

Now, tumours of the intestine are a comparative frequent cause of intussusception in the adult, and here we have a complex tumour-like mass, in itself capable of stimulating extra violent contractions of the bowel, more or less blocking the ileo-cæcal valve, and thereby tending to stimulate further contractions. One other condition must not be forgotten as

FIG. 2.

a very important predisposing cause in this youth's case. I refer to the unusual mobility of the colon owing to the presence of a long meso-colon, so that there was practically a combination of pathological, physiological, and anatomical influences favouring and accelerating the formation of the intussusception.

Since I have been writing up this case Eliot[3] and Corscaden have published their paper on Intussusception in Adults, and they have tabulated brief case histories of some 300 cases. Eighteen of these only are chronic with a known cause, and of these, the only one I have noticed similar to my own is the often-quoted case of Haasler,[4] although in their list are many others suggesting comparison. Haasler's patient was a woman, aged 42 years, with a prior history of trauma followed by severe vomiting. Upon this ensued acute pain about the navel extending to the right iliac fossa. Three weeks later a lump was felt, and attacks of griping pain then occurred at intervals for six weeks, the patient becoming markedly emaciated and constipated. A provisional diagnosis of carcinoma of the colon was made. At the operation a resection of the bowel was performed, and the specimen showed the appendix to be invaginated and forming the apex of the intussusception. Its lumen contained a small amount of fæcal material, and it (the appendix) "seemed not unlikely to be the starting point of the difficulty." Unfortunately, there is no detail as to the extent of the invagination, or whether one or all the coats were involved.

Rolleston's[5] case is the only one in which the prolapse of the mucous membrane of the appendix into the cæcum has been described as far as I am aware; but this was caused by a concretion. Dodds Parker[6] has communicated notes of a case of inversion of the appendix in a woman, aged 43 years. The appendix was microscoped and showed an inflammatory state. In this instance several round worms were found in the alimentary tract. He suggests that one had penetrated the appendix, thereby setting up inflammation, and the inflamed appendix had acted as a polyp, causing invagination and obstruction. Greer[7] gives an excellent description of a case in a child, and, judging from his illustrations, his and my specimens are very much alike. He suggests that the appendix was partly invaginated first, thus exciting the cæcum to contract, but he failed to find any evidence inciting the primary invagination of the appendix. I am emboldened to think that this inversion is possibly mucosa only, resulting from inflammatory action with or without the discharge of a concretion.

My object in quoting these several cases of intussusception of the appendix has been to bring out other evidence to bear on the suggestion that there may be some connexion between appendicitis and intussusception. Under certain conditions an attack of appendicitis may, as in the way described, give rise to the formation of an intussusception, and I believe that as more care is devoted to the investigation of such tumours both by the clinician and the pathologist, the appendix will be found to be the *fons et origo mali* in some, if not in most, of those cases that have hitherto been described as intussusceptions of the ileo-cæcal variety.

FOREIGN BODIES IN THE VERMIFORM APPENDIX.

BY LEONARD A. BIDWELL, F.R.C.S. ENG.,
SURGEON TO THE WEST LONDON HOSPITAL.

SINCE the true nature of concretions in the appendix has been demonstrated, very little attention has been paid to the presence of foreign bodies in the appendix, and a certain number of the profession are inclined to be rather sceptical about them. If, however, a careful examination be made of the fæcal concretions which are so constantly present a foreign body will be discovered in a fair proportion of cases. Although I have never discovered a cherry-stone in the appendix, I have found various other bodies. In some cases these bodies have been free in the appendix and not associated with any fæcal concretion; in the majority of cases, however, the foreign body has formed the nucleus of a concretion. Some of the foreign bodies have been found outside the appendix in an appendix abscess; notable among these were two cases in which the appendix was found to be perforated, and a pin was found loose in an appendix abscess.

In three cases a round shot, such as is used for sporting purposes, was found in the appendix without any concretion and without any sign of inflammation, the operation having been done for symptoms of appendicular colic. In another case a triangular piece of glass, about ¼ in. wide at its base, was found in the appendix without having produced any signs of inflammation of the serous coat, although the mucous membrane was ulcerated. In two or three other cases, where the appendix was apparently normal, fragments of egg-shell were found, and in others fragments of enamel from a saucepan were discovered.

In the second group a foreign body formed the nucleus of a definite concretion or was imbedded in soft fæcal material. A variety of foreign bodies were found, among which the most interesting were hairs. In two cases hairs had evidently been derived from a tooth-brush. In three cases hairs from a camel hair brush have been found, and in these cases I was able to elicit from the friends that the patients had recently been painting and had sucked their paint-brushes. In two or three other cases hairs were found, which most probably were human hairs and had been swallowed accidentally. In all these cases there were signs of more or less severe inflammation about the appendix previous to operation.

In another group of cases seeds form the nucleus of the concretion, the most common seeds being those of strawberries, raspberries, and figs. In a recent case at least 20 fig seeds were found in a soft concretion in the appendix. Grape seeds have also been found in two cases. In one case the nucleus of the concretion was found to be a thorn probably from a rose tree.

I am unable to give any accurate statistics, but my impression is that a foreign body has been found in about 20 per cent. of the appendices which I have removed. The interesting point is that a foreign body by itself sets up very little irritation, and does not produce acute inflammation; it is only when a fæcal concretion forms around it that acute appendicitis will occur. According to many authorities no foreign body or fæcal matter can enter a healthy appendix, and it is stated that some previous inflammation must occur in order to make it possible for the body to enter. If this is the case, a foreign body by itself could not have very much influence in producing appendicular disease. It is, however, more reasonable to suppose that the irritation of the foreign body excites an extra secretion of mucus, which is deposited upon the body, producing the concretion, and so becomes the starting-point of an attack of appendicitis.

Upper Wimpole-street, W.

A CASE OF ERYSIPELAS COMPLICATED WITH MENINGITIS FOLLOWING AN INTRA-NASAL OPERATION; RECOVERY.

BY L. A. PARRY, B.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON, ROYAL ALEXANDRA HOSPITAL FOR CHILDREN, BRIGHTON.

THE patient, a healthy young man, aged 27 years, who suffered from symptoms of nasal obstruction which were not very severe, consulted a London laryngologist, who recommended a submucous resection of the septum. This was done on a Saturday in a nursing home, and on the following Monday the patient travelled to Brighton by train. He was advised by the operator not to leave the home so soon, but no special pressure was brought to bear upon him to induce him to remain longer. On the following Wednesday the patient was suddenly taken ill with symptoms of severe pyrexia, the temperature being 105° F. The only local sign detected was a slightly inflammatory condition of the interior of the nose in the neighbourhood of the operation.

The inflammation spread backwards, and soon the whole pharynx was involved in an attack of erysipelas. This began to subside in a few days, and then the inflammation spread forwards, extended rapidly, and soon the whole face and scalp were covered with the characteristic lesion of erysipelas. The patient appeared to be doing well, when suddenly he was seized with maniacal symptoms, convulsions starting in the right hand, spreading up the arm, and then becoming generalised, conjugate deviation of the head and eyes to the right, strabismus, rigidity of limbs, loss of reflexes, and finally coma, almost complete. Dr. E. Hobhouse, who saw the patient with me, agreed with the diagnosis of meningitis. Up to this time the treatment consisted of the administration of liquor ferri perchloridi, plenty of liquid nourishment, antiseptic gargles and sprays to the throat and nose, and careful nursing. Polyvalent antistreptococcic serum in 10 c.c. doses was now injected every six hours. Sir Victor Horsley saw the patient at this stage and agreed with the diagnosis and treatment. He was able to examine the fundi by means of the new Thorner's reflexless ophthalmoscope, an impossible task with any ordinary instrument. He found evidence of early optic neuritis. He gave a very grave prognosis indeed. Twenty-four hours later improvement began to set in. Consciousness was gradually regained, convulsions ceased, all the rigidity disappeared, the temperature fell to normal, and in about four days the patient was quite well, with the exception of very marked muscular weakness and paralysis of bladder and rectum, causing incontinence of fæces and retention of urine. It was necessary to pass a catheter every few hours. These symptoms gradually cleared up, first the rectal paralysis in about one week, then the bladder trouble a little later. The patient was quite convalescent in about six weeks after the onset of his illness.

There are several points of considerable interest in connexion with this case. Firstly, the recovery of a patient with meningitis complicating erysipelas is extremely rare. Sir Victor Horsley has never seen a case, and I am unable to find any record of one. Sir William Gowers[1] states that: "In any form [of meningitis] if the stage of coma has been reached, death is all but certain." I do not think the diagnosis can be questioned in the face of the symptoms, and of the opinions of Dr. Hobhouse and Sir Victor Horsley.

Secondly, did the antistreptococcic serum have any influence on the result? I confess I have always been very sceptical as to the value of the majority of the various sera so much employed in disease. I used it in this case when meningitis supervened only because I thought it wrong to neglect anything that might conceivably aid recovery, not that I had any real hope from it. Certainly the symptoms seemed to improve after the injections, but I am still left in doubt as to whether it was a case of *post* or *propter hoc*. I might mention that Sir William Whitla[2] makes no reference to the serum treatment under "Erysipelas."

Thirdly, this case raises a very important question, and that is the justifiability of intra-nasal operations for trifling defects. I believe that many nasal specialists are apt to advise such procedures as straightening of deflected septa, removal of turbinate bones, &c., far too readily. The symptoms, if any, caused by a slightly deflected septum, or a moderate enlargement of turbinate bones, are very unimportant, often non-existent. The risks of operation are large, much larger than the operators are inclined to recognise, and I am firmly of the opinion that intra-nasal operations are absolutely unjustifiable unless definite and marked symptoms are caused by the condition of the nose. The case recorded above supports this opinion, and in addition I have just seen a girl of 13 who nearly bled to death after the removal of turbinate bones by a well-known London specialist, the operation being performed under ideal conditions in a nursing home. I know this view is held by men of considerable experience in this town, who have come across many cases in which the patient has been very ill and run considerable danger to life after intra-nasal operations. One of the risks which it would be well for operators to recognise more fully is that run by allowing patients to be up and out travelling directly the operation is performed. The danger of sepsis is great. There is a raw surface in the nose over which air laden with micro-organisms is continually being drawn, and in cabs, railway carriages, &c., there must be great probability of pathogenic germs being present and infecting the wound.

Hove, Brighton.

SOME CLINICAL OBSERVATIONS UPON

SEPTIC INFECTIONS OF THE HANDS AND FINGERS.

BY C. AUBREY PANNETT, M.D., B.S. LOND., F.R.C.S.,
CASUALTY OFFICER TO ST. MARY'S HOSPITAL.

THE hand is probably as commonly infected by pyogenic organisms as any other part of the body. The result of septic infection may prove so disastrous to its mechanism that the ability of its possessor to follow his avocation may be very seriously impaired and in some cases absolutely denied to him. The realisation of these facts has prompted the recording of some personal observations made upon 511 consecutive cases of septic infections of the hand and fingers which applied for treatment, and were operated upon at St. Mary's Hospital. No exhaustive study has been made of the different methods of treatment which have been advocated, nor of the modes of spread of infection in the hand. This has been very thoroughly done in the papers published by Kanavel.[1] Some conception has been gained, however, of the frequency of infection of the different structures in the hand and of the commoner results of it, whilst certain ideas have been formulated as to the best methods of applying well-established surgical principles.

For clinical purposes it is convenient to separate the infections into: A, Those which involve the fingers or thumb distal to their webs, and B, those which affect the hand between the level of the wrist-joint and the level of the webs of the fingers.

A. *Affections of the Fingers.*

The pus which results may be (1) subcuticular or subungual; (2) subcutaneous; (3) thecal; and (4) subperiosteal.

Subcuticular whitlows present no difficulties in treatment, and have only been included in this series if they were accompanied by infection of deeper parts. In the treatment of subungual panaritia it has been found best to remove the whole of the nail as soon as there is any pus at all between the nail and its bed. It is only by such immediate measures that we can be certain of avoiding marked deformity of the nail which subsequently grows. Removal of a portion of the nail when the pus is limited to one lateral half is unsatisfactory. Granulations grow up from the nail bed along the cut edge of the segment of nail which has been left, and help to look up pus under this portion, with the result that frequently in the end the remnant of nail has to be removed, whilst a certain preventable destruction of the nail-bed may have occurred in the interval.

Subcutaneous whitlows are the commonest whitlows met with in the fingers—much commoner than thecal whitlows. The tendon sheaths have been observed to become infected by extension from the subcutaneous tissue of the finger where resort to the knife was refrained from. It appears probable that primary infection of synovial sheaths is uncommon, and the pain of the inflammation in the more superficial structures drives the patient to the surgeon before extension to the tendon sheaths has taken place. Incision in such cases, if sufficiently free, almost invariably prevents them becoming involved, provided the patient can get plenty of nourishing food and can live under hygienic conditions. No one can for long treat such suppurative conditions as are met with in hospital clinics without being profoundly impressed by the powerful influence which proper feeding exerts upon the defensive mechanisms of the body. A large percentage of the cases which get worse in spite of treatment, hesitate in the course to recovery, or relapse, are found, on investigation, to be unable to obtain a sufficient supply of good food, and to live under conditions of overcrowding or other unfavourable hygienic circumstances. Their rapid march to recovery on a "feeding up" diet in hospital amply testifies to the same fact. Other of these cases are the subjects of some constitutional disease. Diabetes is well known to

[1] Allen B. Kanavel: Surgery, Gynæcology, and Obstetrics, September, 1905, November, 1907, January and February, 1909.

predispose to septic infection, but chronic Bright's disease also interferes with defensive and reparative work.

Infection of the tendon sheaths can usually be easily diagnosed before incision. In the case of the subcutaneous whitlow flexion and extension, to some extent at least, are usually possible without great pain. In a thecal panaritium there are extreme tenderness and pain, often localised to one point, and any attempt at extension or flexion of the finger markedly aggravates the suffering. The finger is held rigidly flexed. The synovial sheaths in connexion with the tendons of the little finger and the thumb extend upwards and are continuous with the great anterior carpal synovial sac. Yet involvement of this sac in a thecal panaritium of the thumb or little finger is not common. It only occurred once in this series, and in that case it was of a mild type. When extension takes place to the synovial sheath of a finger the infection is at first confined to one part of the membrane. Round this focus fibrinous adhesions form between the synovial sheath and the tendon, which tend to limit the infection in much the same way as inflammation in the peritoneal cavity becomes circumscribed. This accounts for the *localised* tenderness in a thecal panaritium. If incision is made early extension to the rest of the sheath is prevented. It is not safe, however, to make only a local incision, for with the relief of tension the tendon may be moved in its sheath, and by this means spread the infection to its hitherto unaffected parts. In two cases in this series a stiff finger followed an attempt by limited incisions to preserve the fibrous sheaths where they are opposite the joints of the fingers, a procedure recommended by Kanavel. The infection spread, and in each the flexor tendons sloughed. After a free incision the results are good, and in most cases a moveable finger is obtained. There need be no hesitation in making the incision long and in making it deep.

The subperiosteal whitlow is most commonly seen in the case of the terminal phalanges. Necrosis in the terminal phalanx is common; necrosis in the case of the other bones, unless it occurs as a complication of septic arthritis, when it involves the ends of the bones, is quite rare. If a portion of the terminal phalanx is necrosed a persistent sinus remains, until the sequestrum separates off, and is removed or spontaneously extruded. If the sequestrum has not come away in eight weeks from the time of infection it is advisable to operate. Unless there is a large sinus on the anterior aspect of the terminal phalanx, the sensitive and useful pulp of the finger should be preserved by making antero-posterior flaps, so as to thoroughly lay bare either the anterior or posterior aspect of the terminal bone. A scar in the pulp of the finger is thus avoided. The sequestrum may then be easily separated, or if the whole phalanx be discovered dead it must be removed. This is a very satisfactory procedure, although the pulp subsequently shrinks, and the nail comes to grow over the end of the finger somewhat. In one case, a pianist, the whole of the terminal phalanx, except the extreme base and the articular cartilage, was found to be dead and separated. It was removed. Some movement was retained in the end of the finger, and she was able to play with some skill. Usually, however, the end of the finger is stiff, though it becomes sclerosed and feels almost bony. In such cases it seems that the periosteum of the phalanx on the side opposite the seat of infection has escaped. The operation should always be done with an elastic ligature around the base of the finger. A local anæsthetic has not been definitely proved to delay healing, but general narcosis is preferred.

Another result of deep infections of the finger is a septic arthritis of one of the joints. Very frequently, because the joint involvement in not recognised, the capsule is allowed to perforate spontaneously, instead of being surgically opened. By this time, too, the articular cartilage has usually been irreparably destroyed. The finger, however, frequently heals up, and there is left an abnormally mobile grating joint. With the lapse of time the joint in most cases becomes absolutely stiff. Excision of such joints often leads to no better results, for fibrous ankylosis and adhesion of the tendons produce a stiff finger. In one case such a joint (the metacarpo-phalangeal joint of the little finger) after complete healing of the wound for three weeks, became inflamed again, and an abscess formed round it. An incision was made along the ulnar margin of the joint towards the dorsal surface. The tendons were displaced. The proximal end of the basal phalanx was found to be necrotic and was sawn off, leaving a surface of healthy bone. The cartilage of the head of the metacarpal was almost completely eroded away. The necrotic area was thoroughly scraped. Sterilised vaseline was then interposed between the ends of the bones and the tissues sewn around them. The wound was closed without drainage. A small sinus formed, but soon healed, and a moveable joint resulted.

B. *Affections of the Hand.*

In the 511 cases operated upon there were 60 cases in which the infection was situated in the hand between the level of the wrist-joint and the webs of the fingers. Only four of these were primarily infected on the dorsum. Of the 56 cases infected on the palmar surface, in 20—i.e., 36 per cent.—the infection was localised in the first interosseous interval or the thenar eminence. This can be explained by the fact, as Sappey[2] has shown, that the lymph from a large area of the central part of the palm is conveyed by a collecting vessel across the first interosseous space, where it passes on to the back of the hand and runs upwards on the dorsum. These thenar abscesses are very common. The pus has little tendency to spread inwards to the central compartment of the palm, but spreads with great ease downwards under the lower border of the adductor transversus pollicis, and between the first and second metacarpal bones, to reach the dorsal aspect of the first interosseous space. A simple incision which runs parallel to the direction of the second metacarpal bone, but nearer the thumb than the index finger, so as to avoid the superficialis volæ, is usually sufficient to cure these thenar abscesses. The incision may often be prolonged with advantage on to the dorsum.

Abscess in the central compartment of the palm is uncommon (only four cases in the above series), and this, perhaps, is to be attributed to the fact that the strong central portion of the palmar fascia offers great resistance to the passage of the pus backwards. In the lower part of the palm, however, between the digitations of the palmar fascia which go to the fingers infection can easily pass backwards between the heads of the metacarpals and along the lumbrical muscles to the back of the hand. This is the usual manner in which infection spreads to the dorsum of the hand. When the central compartment of the palm is infected the interossei and the fascia covering them seem to offer much resistance to the backward passage of pus.

In making incisions into the palm the positions of the palmar arches and digital arteries must be borne in mind. General anæsthesia is employed and a tourniquet applied to the upper arm. This is very important, for with a bloodless field one can cut through the palmar fascia and expose important structures, a much freer opening into the abscess cavity by this means becoming possible. One cannot mark out with absolute precision on the surface sites for incision so that no damage may be done to palmar vessels or nerves. It is never necessary, bearing in mind the path of spread to the dorsum, to insert a tube between the metacarpals providing through drainage. The primary incision should be carried downwards towards the web, and a separate dorsal incision made if necessary. The operation should be done speedily. It seems unwise to deprive already infected and damaged tissues of their blood-supply for more than a short time.

The complications, axillary adenitis or lymphangitis, severe enough to necessitate incisions, are rare if the primary infections are adequately treated in an early stage. In only two of the 511 cases did axillary adenitis proceed as far as pus formation. There were two cases of abscesses in the forearm. They occurred in weakly children in a neglected condition. Amputation of a finger was never resorted to.

St. Mary's Hospital, W.

DONATIONS AND BEQUESTS.—Under the will of the late Mr. Edward Snape Grigson King Edward VII. Hospital Fund will receive £2000.—The late Mr. A. Hogg Nasmyth bequeathed £1000 each to the Edinburgh Royal Infirmary and the Dunfermline and West Fife Hospital; £500 each to the Edinburgh Royal Blind Asylum, the Edinburgh Deaf and Dumb Benevolent Society, the Royal Edinburgh Hospital for Sick Children, the Royal Edinburgh Hospital for Incurables (the Longmore Hospital), and the National Society for the Prevention of Cruelty to Children.

A CASE OF CONGENITAL ATRESIA OF THE DUODENUM.

BY W. FRANCIS ROE, L.R.C.S.I., L.M., L.R.C.P.I., L.M.,

AND

ERNEST H. SHAW, M.R.C.P. LOND., M.R.C.S. ENG.,

DIRECTOR OF CLINICAL PATHOLOGY, GREAT NORTHERN CENTRAL HOSPITAL; CONSULTING PATHOLOGIST, HORNSEY COTTAGE HOSPITAL.

Clinical History (W. F. R.).—On Wednesday night, Nov. 4th, 1908, I was sent for to attend a married woman, aged 36 years, in her third confinement. On my arrival I found that she had given birth to an apparently healthy and well-formed male child. She had had an easy labour, and did not trouble to send for the nurse till about an hour before the baby was born. On the occasion of my daily visits no complaint was made to me, either by the mother or the nurse, as to anything abnormal about the baby, except that he did not seem very keen on taking the breast. On Sunday (the 8th) the mother told me that the baby brought up his milk and some "brown stuff" The boy looked quite happy, and I did not take much notice of the fact that he had brought up his milk, nor did I see any of the "brown stuff" which was alleged to have been vomited. The father came to me on Monday morning at 9 20, and told me that the child had suddedly died half an hour before. During the previous day, after my visit, and through the night the child had vomited a considerable quantity of brown material, and continued to pass black motions from the bowel. On going to the house I found the child dead, and its face and clothes stained with a brown fluid which had apparently come from the mouth. The napkin contained meconium. As I was at a loss to know what to certify as the cause of death I obtained permission to perform a necropsy.

The child was well developed and showed no external signs of disease except that the abdomen was rather distended and hard. The lungs and heart were normal. Upon opening the abdomen a distended stomach was found to be filling up that cavity; it had apparently an hour-glass constriction towards the pyloric end. The stomach contents consisted of a quantity of "brownish black" fluid material. The intestines had not been distended. The other organs were normal.

Specimen (E. H. S.).—The specimen consists of the stomach and duodenum of an infant; it was stuffed with cotton wool, and hardened in as near the natural shape of the viscus as could be made out. At first sight there appears to be a large stomach with a deep constriction at about the junction of the proximal two-thirds with the distal third, the œsophagus entering the organ in its natural position and at the other end a narrow tube leaving the middle of a blind and bulbous extremity. On further examination, however, the constricted portion is seen to be the pylorus, a well-marked muscular ring about half an inch wide representing the pyloric sphincter. The dilated part distal to the pylorus is the duodenum, which gradually expands to a tube 1½ in. in diameter and then rather abruptly terminates. The lumen of the duodenum is completely lost at this point, and no dimple or pit can be made out in the mucous membrane. Projecting from the outside of this blind end is a narrow tube with a thin wall, and a lumen about ¼ in. in diameter. The mucous membrane of the tube is irregularly folded. There is a very slight constriction externally at the junction of the two parts. The appearance presented by the narrow tube projecting from the dilated proximal part of the duodenum somewhat resembles that of a vermiform appendix arising from the cæcum. The dilated duodenum is covered with peritoneum near the pylorus only. The lining membrane is quite smooth; this is in marked contrast with the lining membrane of the stomach, which is thick and thrown into well-marked folds. A narrow bile-stained duct enters the wall of the duodenum behind just at the commencement of the narrow part. A bristle can be inserted into the tube, but cannot be made to enter the lumen of the bowel. This is evidently the common bile-duct. A passage must have existed during life, because meconium was present in the intestines, but owing to shrinkage it has become difficult to demonstrate. A second minute tube by the side of the first one apparently represents the pancreatic duct. A bristle can only just be inserted into this opening and cannot be passed into the duodenum.

Just inside the pylorus there is a narrow, deep, and slit-like pit about 5/16 in. long by 2/16 in. deep; it is placed at right angles to the long axis of the pylorus, and separated from the beginning of the duodenum by a bridge of mucous membrane about 1/8 in. wide. A piece has been cut out, and the mucous membrane can be seen dipping down into the pit and covering its depth. The sectional view of the depression reminds one of a similar section through the laryngeal ventricle. The pyloric sphincter is about 1/8 in. thick; it ends abruptly at the duodenal junction, but fades off gradually towards the cardiac end of the stomach. The stomach is much enlarged and its walls hypertrophied. Measurements along the curvatures work out as follows: lesser curvature, 2½ in. from œsophagus to pylorus; greater curvature, 7 in.; depth from lesser to greater curvature, 1¾ in. The measurements of the dilated duodenum are: 2 in. along the upper border from pylorus to the constriction, and 3½ in. along the lower border between the same points.

Microscopic examination—(*a*) *Pylorus and adjoining duodenum*—Well-marked bundles of unstriped muscle with a lining of ordinary mucous membrane. There are numerous scattered large glands beneath the muscularis mucosa of the duodenum (Brunner's glands). The cells of the glands are tall and columnar in shape.

(*b*) *Pouch in pylorus.*—The mucous membrane on either side of the depression is thick and well formed. At the bottom of the pit the orifice of a large branched duct is seen lined by columnar cells. Around this duct there are large irregular collections of gland tissue; some of the groups are well defined and are oval and round in outline; on either side isolated glands are seen penetrating the muscular coat. The cells are columnar in shape, rather short, and contain large nuclei. They are shorter than the cells of the glands seen in the first section. Large numbers of small round cells are present in and around the groups of glands. The mass of glands appears to have penetrated the whole thickness of the muscular wall.

An interesting problem is presented by these glands. Are they Brunner's glands or an accessory pancreas? In favour of the first is the position of the glands; in favour of the second are the fact that they form a definite collection of lobules around a central duct and the gland cells are smaller than those seen in the first specimen, which are undoubtedly Brunner's glands.

The above are the facts; any opinion one may feel inclined to form one way or the other is purely speculative. Developmentally they are both offshoots from the intestinal glands. Brunner's glands stop short and scatter themselves beneath the muscularis mucosa. The pancreatic glands go right through and form a mass outside the wall of the intestine. The above collection may represent an exaggerated collection of Brunner's glands or a minute pancreas.

The specimen is a most interesting one and is rare. Professor Arthur Keith has investigated the literature of this malformation, and has succeeded in finding seven other specimens. He quotes Bland-Sutton's opinion that the occlusion is probably associated with the outgrowth of the embryonal cells of the liver and the pancreas. It occurs at the junction of the two morphological parts of the alimentary canal—the fore and mid gut. Forssner finds that the Vaterian segment of the duodenum is occluded by the proliferation of its epithelial lining during the greater part of the second month of development. The epithelial plug, failing to break down as development proceeds, leads to an occlusion of the bowel at that point. The specimen is now preserved in the museum of the Royal College of Surgeons of England.

THE "I.K." TREATMENT FOR TUBERCULOSIS.—In an annotation published in THE LANCET of Sept 16th, dealing with this subject, we omitted to mention that Dr. Carl Spengler's book is published by the Verlag von H Erfurt, Davos Switzerland, at the price of 12 marks. Its full title is, "Carl Spengler Tuberkulose- und Syphilis-Arbeiten (1890–1911). Herausgegeben von seinen Schülern und Freunden." Pp. 505.

Reviews and Notices of Books.

In and Out of Parliament: Reminiscences of a Varied Life. By the Right Hon. ROBERT FARQUHARSON, P.C., M.D., LL.D. London: Williams and Norgate. 1911. Pp. 338. Price 12*s.* 6*d.* net.

Dr. Farquharson has had a sufficiently varied career to afford ample opportunities for a many-sided view of life. This book discloses a sense of happiness bubbling over, an almost juvenile naïveté, and considerable sense of humour; moreover, it is written with, at times, unconventional frankness as to people and things, while treating the cherished convictions and opinions of many in a manner which, were it not for the obvious ingenuousness of the writer, would run perilously near arousing resentment.

The book is divided into two parts, in the first of which Dr. Farquharson describes his childhood and early education, and gives charming glimpses of Edinburgh life, especially university life, in the middle of the last century, with recollections of Goodsir, "Johnnie" Struthers, Gregory, Wilkinson, "Woody fibre" Balfour, Edward Forbes, Sir J. Y. Simpson, Bennett, John Brown, Syme, "Dismal Jimmy" Spence, Ghiene, Matthews Duncan, and others on the medical side; and Blackie, Aytoun, Chalmers, Lord Cockburn, Alexander Smith, and others on the academic side. "The physiology of those days," says Dr. Farquharson, "was not, as it has now become, a kind of blend of mathematical chemistry and mechanical engineering." The author tried his hand in art. To a description of his "hopeless struggle in pencil, chalk, and water colours" he adds a few sane reflections as follows: "But at the same time, I would advise everyone to learn to draw even a very little; for it steadies the hand and clears the vision, and enables us to look at nature with more pleasure, and with an observant and appreciative eye—and best of all, it helps us to enjoy pictures intelligently, because we can understand what artists are trying to do, what their aims are, and what their difficulties." Dr. Farquharson's life as an army surgeon, first in the Royal Artillery, and subsequently in the Coldstream Guards, and his career in civil practice, as medical officer to Rugby School under Dr. Temple, and subsequently as a London physician and lecturer at St. Mary's, afford ample opportunities for the introduction of piquant incidents and shrewd reflections. For instance, he relates how at Rugby, finding the well-known cricketer, Yardley, seedy, he was unable offhand to give a dogmatic opinion as to the nature of the illness. "On which," he says, "I was summoned to Jove's awful presence, and the head master, in his most abrupt and grating tones, snapped out: 'You damage yourself by want of decision.'" This represents only too well the mental attitude of a certain portion of the public, particularly of those who are, or at some time have been, men in authority, an attitude which puts an unfortunate premium upon ignorant dogmatism. Concerning this period of his life the work abounds in reminiscences of Sir William Gull, Sir William Fergusson, Sir William Jenner, Sir Andrew Clark, Sir Spencer Wells, Mr. Ernest Hart, and other well-known personages in medicine, not to mention many dramatic, musical, and other celebrities. In the course of his army career Dr. Farquharson was stationed in Dublin, and he speaks of the wonderful amount of very high-class work turned out of the Dublin hospitals and medical schools.

In 1878 Dr. Farquharson succeeded his father as the Laird of Finzean, Aberdeenshire. "The succession to a property in the north," he says, "is rather a serious matter. To begin with, the executors grab the first year's income, so that during that period the heir, perhaps to a large income, has practically to live on nothing. Then the younger children, under the law of entail, are officially provided for, by intercepting, according to numbers, two or three years of gross rental; and finally comes the succession duty, which, though then mild compared to Harcourt's death duties, meant a considerable money payment at a most inconvenient time." The later chapters of the first part are occupied with shrewd observations of men and things as they appeared to the author at Rugby, abroad, and in London, to which are added some interesting notes on Aberdeenshire people and the Free Church.

Part II. is concerned with Dr. Farquharson's Parliamentary career as Liberal M.P. for West Aberdeenshire, which covered the period between 1880 and his retirement in 1906. He was a keen admirer and a loyal follower of Gladstone, whom, nevertheless, he seems to have regarded with some awe, for he contrasts the latter's lofty and abstracted demeanour with "the gracious smile and pleasant words of friendship" of Disraeli. He describes with considerable humour the process of electioneering and the details of life about the House; but in a chapter on Parliamentary scenes the curtain is lifted on certain phases of what may be called the business of politics that hardly tend to inspire respect for the political career or politicians generally. It is only too evident that the quest and retention of power bulks altogether too large among politicians of all kinds in proportion to the conscientious sense of responsibility for the welfare of the country as a whole. There are many interesting anecdotes and character impressions in the chapter on the author's political contemporaries. There is little of medical interest in this part of the book, and we look in vain for any review of the measures of medical concern that engaged the attention of Parliament while the author sat there to lend the weight of professional opinion to the debate, which, we believe, it is generally conceded that he did in a creditable manner. In the chapter on health and teetotalism he refers to golf as follows: "I envy those who have fallen a victim to its fascination, for to me it is the most irritating and even exasperating of all sports; and I was very glad when THE LANCET uttered some words of much needed warning to over-tired and worried people who tire and worry themselves a great deal more in vain efforts to acquire even a moderate proficiency in a game of such elusive and uncertain quality. ..." He has a few words on over-dining, over-smoking, the "jaded Londoner," and the use of alcoholic beverages.

Dr. Farquharson is no devotee of intemperate temperance. Speaking of those who tell us "that every drop of drink is a slow poison" he says: "If any of these well-intentioned but mischievous folk—for whom I cannot withhold a kind of sneaking respect—ask my reasons for taking a cheerful glass my answer always is the same: 'I drink because I like it'; and then there is not another word to be said" It is to be feared that this would only change the field of debate to "a hundred and one reasons why you ought not to like it." There are several excellent photographs in the book, most of them portraits of the author; but here his sense of humour precludes the appearance of egotism, in that five of them are reproductions of clever caricatures by Harry Furniss, Leslie Ward, and E. T. Reed, all equally redolent of kindly raillery.

Those readers who do not know Dr. Farquharson will surely find much to interest and amuse them in this book; while those who do know him will find the fount of their affectionate regard well up.

Klinische Pathologie des Blutes nebst einer Methodik der Blutuntersuchungen und Spezieller Pathologie und Therapie der Blutkrankheiten. Von Dr. ERNST GRAWITZ, Professor an der Universität zu Berlin. Mit 45 Figuren im Text, 6 Tafeln in Farbendruck und einer Tafel mit mikrophotogrammen. Vierte vollständig neu bearbeitete und vermehrte Auflage. Leipzig: Georg Thieme. 1911. Pp. 1011.

IN reviewing this truly colossal work on a subject of which but a few years ago all that was known could have been put into a few pages, we may well start by expressing our regret at the death of its author, an extraordinary professor of medicine in the University of Berlin and director of the medical department of the Charlottenburg Hospital (as chronicled in THE LANCET of August 5th). The book is dedicated to the author's brother, Professor Paul Grawitz, the pathologist of Greifswald.

In the whole story of the doctrine of the origin of the blood cells, the author thinks the most important point is that their origin is not confined exclusively to red marrow, spleen, and the lymphatic system, but that the white cells especially have a nearly ubiquitous origin in all tissues of the body under different forms of stimuli, so that, as far as leucopoesis is concerned, we have returned to views enunciated independently by Paul Grawitz and Stricker from 20 to 30 years ago.

Part I. deals with the methods of investigating the blood—how to obtain blood for histological and bacteriological purposes; and a full account is also given of physico-chemical methods. The whole occupies 79 pages.

Part II., on the physiology of the blood (pp. 79–304), deals successively with physiological changes due to age, sex, pregnancy, period of day and year. Individual differences, the total quantity of blood and its viscosity, changes produced by vaso-motor influences, blood coagulation and its relation to hæmophilia are all considered. Then follows a description of the formation of red blood corpuscles during fœtal and extra-uterine life, with a very full account of the red cells of human blood, under such heads as their form, functions, structure, pathology, and hæmoglobin content. Megalocytes, microcytes, and poikilocytes, the different relations to staining reagents, and how long they live and how they disappear in the circulation, come in next for notice. To the leucocytes, apart from their sources, about 50 pages are devoted, while leucocytosis occupies about 30 pages, and is dealt with in its physiological forms—e.g., the digestive and myogenic—as well as those forms occurring during and after pregnancy, and in the new-born and at death. The pathological forms are classified as post-hæmorrhagic, inflammatory, cachectic, and toxic. A short chapter on the blood platelets follows. These, the author asserts, arise chiefly, but not exclusively, from the nuclei both of the red and the white corpuscles.

Part III. (pp. 305–696) deals with anæmic conditions, under such headings as anæmias in general, transfusion of blood, pernicious anæmia, chlorosis, leukæmia, and pseudo-leukæmia. This is a most comprehensive and detailed survey.

Part IV. occupies about 300 pages and deals with clinical serology (part of this is written by Dr. Werner Schultz), precipitins, hæmolysins, agglutinins, the side-chain theory, opsonins, anaphylaxy, anti-ferments, and kindred subjects. A very interesting chapter on blood poisons follows. The blood in constitutional diseases, and diseases of the digestive, circulatory, respiratory, nervous, and renal systems, is successively dealt with. Infectious diseases and animal parasites come next, and the end is reached with a short discourse on carcinoma and other malignant new formations.

We have contented ourselves with giving the scope of the author's work, which is truly comprehensive. It is at once a quarry and a treasury, and when we add that there is an abundance of references to the literature of the subject the work cannot fail to prove to be of great utility to, and a comprehensive source of reference for, the physiologist, pathologist, and clinician.

Methodik der Klinischen Blutuntersuchungen. Von Professor Dr. ERNST GRAWITZ zu Berlin. Mit 35 Figuren im Text und 6 Tafeln in Farbendruck. Fourth edition. Leipzig: Georg Thieme. 1911. Pp. 79.

THIS is a reprint of the first 79 pages of the author's large work, and the plates are the same. On p. 77, when speaking of iodophil substances in leucocytes, a reference is made to the chapter on leucocytes, but the larger work itself is not mentioned by name. The book is an excellent epitome of the subjects with which it deals.

The Grouse in Health and Disease; being the Final Report of the Committee of Inquiry on Grouse Disease. Two volumes, pp. 512, 151, xxiii. London: Smith, Elder, and Co. 1911. Price £2 2*s.* net.

THE Final Report of the Committee of Inquiry on Grouse Disease, which has been lately issued, will be found not only of great interest to sportsmen, but also a most valuable book of reference to all scientific men; for while it deals with questions relating to grouse preservation and the management of moors, it also shows the vast amount of scientific research that has been employed in working out the pathology of the diseases to which grouse are most subject, and in ascertaining the pathogenic properties of the numerous parasites which infest them both externally and internally, as well as the life-history of these parasites.

In the second part of the first volume, which has for its sub-title "The Grouse in Disease," the objects of the committee are set forth by Lord Lovat, the chairman of the committee, under six headings, and these define the task which the committee set itself to accomplish. Lord Lovat's headings, or questions of reference, may be briefly summarised as follows: (1) Whether the sickness described universally as "grouse disease" is a single disease with individual characters peculiar to it alone; (2) whether a distinction can be discovered between recorded outbreaks to justify the opinion that two distinct forms of disease are confused under one term; (3) in the event of finding in favour of the belief in two or more distinct epidemic diseases, what are their causes and effects, and by what titles and characteristics are they to be known; (4) in the other event of finding in favour of the belief that only one form of epidemic disease exists, is Professor Klein's view right, that the only serious disorder among grouse is caused by a bacillus of the B. coli group producing lesions of an acute pneumonia in the lungs, with the characters of an acute infectious epidemic disease, or (5) is Dr. Cobbold's view right, that the outbreaks of disease among grouse have been caused by a nematode worm, Trichostrongylus pergracilis, causing certain lesions in the cæca leading to extreme emaciation? (6) is there any other form of "grouse disease" that has been hitherto overlooked?

All these questions are carefully discussed in the light of research work carried out on the moor, in the laboratory, and on the experimental area in Surrey, and each one is unhesitatingly answered by the committee. After remarking that, with the exceptions of Dr. Cobbold and Professor Klein, none of the older writers had made a careful study of "grouse disease," but had simply given their opinions, "hopelessly mixing up observed facts with unsound theories, and primary with predisposing causes," the committee gives the conclusions at which it has arrived in the shape of the answers to the six questions formulated above. The answers may be briefly summed up as follows: (1) The

sickness which in the past has caused "grouse disease" among adult birds is a single disease with clearly defined characteristics of its own; (2) and (3) it follows that if the two forms of "grouse disease" hitherto described as distinct diseases are one and the same there is no need to differentiate between them; (4) that "grouse disease" is not due to Klein's bacillus; (5) that adult "grouse disease" is due to Dr. Cobbold's Trichostrongylus in large numbers in the cæca; and (6) that another form of "grouse disease" exists which has hitherto escaped notice; this is caused by the presence of Eimeria (coccidium) avium in the alimentary tract and is called in the report coccidiosis, but it is fatal only to chicks, whereas the records of "grouse disease" refer only to mortality among adult grouse. Here we have the finding of the committee that grouse disease is caused by Cobbold's strongyle, and the remainder of this part of the report shows how this was scientifically proved.

An introduction by Lord Lovat shows how the committee originated, and it should be remembered that though the committee is described as a Departmental Committee of the Board of Agriculture, all the expenses have been met by private subscription, and no grant of public money has been made towards this valuable work. The life-history of the grouse is dealt with by Mr. A. S. Leslie, who has acted in an indefatigable manner as secretary to the committee. Dr. Wilson, at present with Captain Scott on the Antarctic Expedition, describes the plumage changes of the red grouse, also giving beautiful coloured illustrations of these changes. The food of the grouse is next considered, with tables showing the nature of the food taken and the weight of food in the crop at different hours of the day; the insect food of the grouse is described by Mr. P. H. Grimshaw, who in Appendix F of the second volume gives a full account of all the insects found in the crops of grouse examined by him. Mr. Leslie deals with the water-supply. The very important subject of grit is considered by Mr. H. Hammond Smith and Mr. R. H. Rastall, who worked out their conclusions by making a collection of grits found in the gizzards of all game birds, when it was seen that all birds do better on quartz grit, and that it was essential to grouse from the very earliest age; it was found in the gizzard of a chick not 48 hours old. The physiology and anatomy of the grouse are well dealt with by Dr. Wilson, and here again the coloured illustrations are remarkably good.

The chapter on grouse disease discusses the divergent views obtaining on the subject before the work of this committee. The work done by Dr. Seligmann in the early days of the committee enabled them to decide not to proceed further with Professor Klein's theory, but to work at the parasites of the grouse as potential disease carriers or producers; for, as Dr. Wilson points out, during the whole period of the inquiry no birds have been found dead without loss of weight. In this part of the report we have most interesting accounts of the nematode and cestode worms found in grouse, by Dr. E. A. Shipley, while Dr. Leiper describes the development of the Trichostrongylus pergracilis and the manner in which it obtains entrance into the alimentary tract of the grouse, a chapter that deserves careful study. The work by Dr. H. B. Fantham on the Eimeria (coccidium) avium is exceedingly interesting; the development of this micro-organism, its life-history and methods of reproduction, are minutely described, and the chapter is well illustrated, constituting a fine piece of original work. Another most interesting chapter is by Dr. L. Cobbett and Dr. Graham Smith, on the pathology of grouse disease, giving an account of their experiments and investigations.

The remainder of the report is chiefly concerned with the management of moors, such as careful scientific burning and draining, by Lord Lovat, and the important question of stock. Mr. Hammond Smith gives an account of grouse in captivity, and describes the experimental area at Frimley in Surrey, where grouse were kept for five years, and though at first there were many failures, yet in 1910 41 grouse chicks were hatched from 46 eggs. Mr. Grimshaw in this part of the work has an excellent paper on the heather beetle and its ravages.

The report is a model of what such work should be, and is a good example of the way in which scientific medicine is now bound up with every phase of social life.

Treatment of the Diseases of Children. By CHARLES GILMORE KERLEY, M.D., Professor of Diseases of Children in the New York Polyclinic Medical School. Second edition, revised. London and Philadelphia: W. B. Saunders Company. Pp. 629. Price 21*s*.

THIS volume is dedicated to the author's pupils at the New York Polyclinic Medical School and Hospital, and as such it is not intended as a text-book for unqualified students or as a work of reference for specialists in pædiatrics; this is Dr. Kerley's apology for the particular form which his useful book takes. The work is strongly impressed with the personal element, a feature which will make it all the more acceptable to those who have benefited by the author's oral teaching.

There is very little to criticise, for the author seldom leaves the beaten tract of pædiatrics except in matters of treatment, and as regards therapeusis generally it may be said that each man must be a law unto himself, and he must be guided by his own experience. If we do not agree with many of the methods recommended by Dr. Kerley, it by no means follows that, under different climatic conditions and in different hands, the procedures he recommends may not be followed by the best possible results.

His advice in cases of pyloric stenosis to resort to early operative interference seems to us, however, to strain somewhat severely the charitable view that we are disposed to take of his departures from recognised practice. We are also inclined to dispute the statement that boiled milk is less digestible than unboiled milk, owing to precipitation of lime salts; under ordinary conditions this is one of the pre-stages of gastric digestion. His views on the capacity of the young infant to digest starch are somewhat circumscribed, and his experiments to elucidate the capacity are faulty. Boiled starch may undergo fermentation in the alimentary tract, and leave no residuum to react to the von Jaksch iodine test. Moreover, we know, on general principles, that young infants very soon learn to digest any particular variety of food, provided the probationary experiences are adequately graduated. But the general statement that young infants are capable of digesting starch without qualification is distinctly misleading.

Of mucous colitis the author says (p. 218) that this is a rare disease in children. This may be so in America, but in England it is certainly one of the commonest, in both its chronic and its acute forms. For treatment he recommends olive oil injection at bedtime, and if no stool results in the morning he advises a glycerine suppository. He altogether discountenances the use of the irrigator under such conditions. The Plombières method of using the rectal douche does not seem to be known to Dr. Kerley, or at any rate he does not avail himself of its conspicuous advantages in describing the procedure of intestinal lavage. The hypodermic injection of normal saline in urgent cases of collapse does not commend itself to him. He says in cases in which hypodermoclysis—an ugly term, but we use the author's own expression—is most required "the fluid will not be absorbed owing to the lowered vitality of the patient. Those whose

tissues are able to take up the water appear to do well without it."

Taking it all in all, this is a good book for general practitioners; but it is neither inspiring nor altogether convincing. The arrangement of the contents is clear and the printing excellent. Dr. Kerley is undoubtedly at his best when he deals with the general aspects of disease and the hygiene of infancy and early childhood.

La Neurasthénie Rurale. Fréquence, Causes Sociales et Individuelles. Études Psychologiques et Cliniques de la Neurasthénie chez le Paysan Contemporain. By Dr. RAYMOND BELBÈZE. Paris: Vigot Frères. 1911. Pp. 222. Price 3 50 fr.

Dr. Belbèze, practising in a purely rural district in France, finds that no less than 30 per cent. of his patients belong to the neurasthenic class, and has written an interesting little volume on the type of case commonly met with, based on a record of 200 observations. He attributes the great frequency of neurasthenia partly to local circumstances—unsatisfactory conditions of life, depopulation, &c.—and partly also to the "neurasthéniculture" of the day. Consanguinity, inadequacy of nutrition, and intoxications of one kind or another are all stated as factors of considerable importance. Among the symptoms which Dr. Belbèze's patients show he is struck by the constancy of the occurrence of aboulia, of fear, of desire to avoid any sort of responsibility. No one who has had any experience of medical work in remote country districts can have failed to notice how great is the tendency to "rumination" among certain individuals; with little or nothing to interest them beyond the daily round, the common task, they become introspective and almost inevitably hypochondriac. Dr. Belbèze designates this characteristic symptom "phrontidophilia," and considers it of much significance. Bearing, as it does, on problems which meet the country practitioner of to-day in all countries, this little volume will well repay perusal.

Meat and its Inspection: a Practical Guide for Meat Inspectors, Students and Medical Officers of Health. By A. R. LITTLEJOHN, M.R.C.S. Eng., L.R.C.P. Lond., M.R.C.V.S., D.P.H. R.C.P.S. Lond. London: Baillière, Tindall, and Cox. 1911. Pp. 399. Price 10*s.* 6*d.* net.

THE writer of this volume is entitled to speak with authority, as he is both a medical man and a veterinary surgeon; he is also engaged in public health work and bacteriology. The work does not profess to be a text-book of the subject, but is intended as an aid to those who have to deal practically with meat inspection, such as meat inspectors and students for a public health diploma. After an introductory chapter on the methods of slaughtering and dressing carcasses, with a brief *résumé* of the statutory powers of the medical officer and his inspectors, a full description is given of the appearances of the carcasses of healthy animals. The third chapter, on preserved meat, is rather slight, considering the enormous quantity of such food that is consumed at the present day; a fuller description of the different methods of preservation by heat (only one is mentioned) and of the points to be considered in examining tins would have been useful. The various physiological and pathological conditions which make meat unsound are reviewed clearly and fully. Then follows a good account of the parasitic affections of animals used for food; but we do not find any reference to the recent researches of MacFadden and Leiper on onchocerciasis, the condition known as "worm kernels" that has been extensively found in cattle in Australia, the United States, and elsewhere, due to thread-like worms, transmitted through the medium of some biting insect (see THE LANCET, Feb. 4th, 1911, p. 317). The last chapter, from p. 241 to the end of the book, more than a third of the whole, consists of a verbatim transcript of portions of various Public Health Acts, by-laws, and regulations, which are usefully brought together, but can hardly be credited to the author. The illustrations of pathological conditions are excellent; most of them are drawn by the author himself, and they have been very well reproduced.

Nephrocoloptosis: a Description of the Nephrocolic Ligament and its Action in the Causation of Nephroptosis, with the Technic of the Operation of Nephrocolopexy, in which the Nephrocolic Ligament is used to Immobilise both Kidney and Bowel. By H. W. LONGYEAR, M.D., Professor of Gynæcology and Abdominal Surgery, Detroit Post-Graduate Medical School. With 88 special illustrations and a coloured frontispiece. London: George Keener and Co. Pp. 251. Price 12*s.* 6*d.* net.

THE title of this work is so full that it goes far to explain the contents of the book. The author holds that nephroptosis cannot occur without a coloptosis—that is, a settling down of the colon. The kidney and the colon are, he claims, linked firmly together by the nephrocolic ligament, which he describes as an irregularly shaped aggregation of fasciculi, passing from the perirenal fascia, or Gerota's capsule, to the posterior wall of the ascending or descending colon. This band is called by some Longyear's ligament. The factors necessary for nephroptosis are, in the opinion of the author, (1) a weak or absent hepatocolic ligament; (2) a loose attachment of the kidney at its hilum and to Gerota's capsule; (3) a strong and short nephrocolic ligament; and (4) prolapse of the cæcum and of the ascending colon or of the descending colon. Dr. Longyear's method of operating consists in anchoring the nephrocolic ligament to the perinephric fascia and to the transversalis aponeurosis. Notes of 56 cases are given in which this operation has been performed; there have been no deaths; 35 cases were entirely relieved; 16 were partially relieved, and in 5 cases no report was obtained. In the book the reader will find a not immoderate claim for the benefits likely to follow the operation which the author has devised.

Clinical Lectures on the Acute Abdomen. By WILLIAM HENRY BATTLE, F.R.C.S. Eng., Surgeon to St. Thomas's Hospital and Joint Lecturer on Systematic Surgery in the Medical School, &c. London: Constable and Co., Limited. 1911. Pp. 107. Price 4*s* net.

THE importance of the early recognition of acute abdominal conditions is equalled only by the difficulty which is often encountered in their diagnosis. With regard to treatment, at one time all the surgeon could do was to follow acute abdominal cases to the necropsy room, but now the results are very different. Still, the medical practitioner, called suddenly to a patient with a distended and painful abdomen, often feels entirely at a loss how to deal with the case. How can he tell what is going on within the abdomen? Does it need immediate operation or may delay be justifiable? It is only by studying the subject carefully beforehand that he will be in a position to deal with such an emergency.

Mr. Battle recently delivered some clinical lectures at St. Thomas's Hospital on what he termed "the acute abdomen." We published these lectures in our columns[1] and are glad to see them in book form. They deal with the following subjects: The influence of the appendix vermiformis and its diseases on the production of the acute abdomen; the treatment of acute appendicitis with peritonitis; pathological perforations of the digestive tract; acute intestinal obstruction; the rarer causes of the acute abdomen; the acute abdomen due

[1] THE LANCET, Jan. 27th (p. 201), Feb. 3rd (p. 273), and Feb. 17th (p. 429), 1906.

to disease of the uterus and its appendages; and, lastly, some neuroses which may cause symptoms of urgency. Mr. Battle is emphatic in speaking of the need for immediate operation in most of the cases of acute abdomen, and he cites individual instances which show the benefits resulting from timely operative interference and the harm that may follow delay. It is interesting to note that he employs silk for all abdominal sutures and ligatures, and holds that catgut should not be used in acute abdominal cases, as it is apt to soften and to yield too quickly should any strain be placed on it.

The style of the book is very readable and the lessons eminently practical.

LIBRARY TABLE.

Modern Surgery, General and Operative. By JOHN CHALMERS DA COSTA, M.D., Professor of Surgery and Clinical Surgery in Jefferson Medical College, Philadelphia. Sixth edition, thoroughly revised and enlarged, with 966 illustrations, some of them in colours. London and Philadelphia: W. B. Saunders Company. 1910. Pp. 1502. Price 24*s.* net.—The incessant progress of surgery makes it imperative that every new edition of a text-book should be thoroughly revised, and the author of this trustworthy treatise on surgery has done his best to make his work represent modern surgery. To mention only some of the additions, we have Crile's arterio-venous anastomosis for transfusion of blood, the operative treatment of recent fractures, the use of positive and negative air pressure in intra-thoracic surgery, Murphy's method of treating general peritonitis, and Bier's treatment and Wassermann's test. The work is written simply, in a style suited for the learner, and the numerous illustrations should prove useful. A few points suggest themselves for criticism, such as the advice that a rodent ulcer "requires scraping and cauterisation," but it is inevitable that in so extensive a work there should be some small blemishes. These, however, hardly detract from the general high character of the work. It can confidently be recommended to students as a trustworthy text-book, and a very complete index renders the work easy of reference.

The Essentials of Food. By DONALD STEWART, M.D. London: John Bale, Sons, and Danielsson. 1911. Pp. 182. Price 3*s.* 6*d.* net.—This is a handy volume designed for popular reading, written by a medical man of experience, who does not appear, however, himself to have made any special study or research in dietetics. He quotes largely from Chittenden and seems to adopt his protein standard (pp. 77 and 155) without reserve; but on p. 33 he gives 120 grammes protein as the amount in a "standard" diet. The phraseology used is vague—e.g., "the words nitrogenous, albumen, and proteid signify some obscure modifications of the same thing" (p. 46); sometimes it is erroneous—e.g., "of course there are no carbohydrates or starches in animal foods" (p. 19); milk sugar is an animal carbohydrate. One hesitates to question the author's instructions for making porridge, but does he really take (p. 94) only "one to three *teaspoonfuls* of oatmeal to every pint of water"? Even in a popular work on a small scale it is not commendable to write: "The fuel values are termed calories. The word means heat." The word has a perfectly definite meaning which can be stated shortly and without difficulty. On p. 134 we are told that "food is therefore fire," and lower down that "food is fuel." In explanation of the formula H_2O we read (p. 13) that the figure 2 in the symbol "means not two 'atoms' of the hydrogen, but two elements have to be taken with one of oxygen to form water." We are unable to divine the conception present in the author's mind. Eccentricities of spelling, such as "arson" for argon, phinol, and lypolytic, occur frequently. There is, however, in the book a good deal of information of a practical character expressed in popular language and in a readable form. Possibly the author did not revise his work carefully.

The Prevention of Dental Caries. By STANLEY W. R. COLYER. Pp. 23. Price 6*d.*—*The Prevention of Dental Caries.* By J. SIM WALLACE. Pp. 45. Price 1*s.* 6*d.* London: The Dental Manufacturing Co. 1911.—These are two very interesting essays, and would well repay careful perusal. Dr. Colyer holds the view that the destruction of the enamel in the early stages is brought about principally by the food in a fluid state, the fluid being held in contact with the teeth by capillary attraction, a view supported by a consideration of the usual sites of caries. The prevalence of caries in modern times he attributes to the more easily fermentable character of the carbohydrate food and the increasing number of articles of food in a partly acidly fermented state, which constantly introduce, not only acid, but also acid-producing organisms. Dr. Sim Wallace's thoughtful essay contains much that is useful and suggestive. He considers, and with good reasons, that caries may be easily prevented by careful attention to the dietary. The diet, he considers, should be of a kind to stimulate mastication, and the last food taken should leave the mouth clean, or, at least, free from carbohydrates. The dissemination of knowledge necessary for the prevention of dental caries must, he thinks, come mainly through the medical profession, and therefore no efforts should be relaxed in bringing before their notice the reasons for considering the hygiene of the mouth a most important part of preventive medicine.

Crime and Insanity. By C. A. MERCIER, M.D. Lond. London: Williams and Norgate. 1911. Pp. 255. Price 1*s.* net.—The task of compressing the treatment of a large subject into a small space is never an easy one, and of this the little book before us is an apt illustration. Dr. Mercier has done his best, but even his faculty for marshalling ideas and his powers of verbal expression leave an impression of sketchiness in the work. The nature of insanity and of crime, and the relations between the two, form the subject-matter of the book. Most readers, whether legal or medical, will turn with interest to a perusal of the opinions enunciated upon the vexed question of responsibility. While recognising that crime may be, and often is, the result of insanity, and that some persons are so completely insane that we are not warranted in punishing them for any offence they may commit, the author is yet of opinion that when an insane person commits a crime that is not the consequence of his insanity, it is no more just or proper to excuse him from punishment than to excuse a sane person. The mitigated responsibility here outlined has perhaps a larger number of supporters on the continent than in this country, but we have little doubt that the opinions on this subject advanced by Dr. Mercier will, with the aid of his persuasive pen, ultimately prevail. On the whole this little book is most interesting, and must serve to stimulate thought on the subject it treats.

Radiumnormalmasse und deren Verwendung bei Radioaktiven Messungen. By E. RUTHERFORD. Leipsic: Akademische Verlag-gesellschaft. 1911. Pp. 50. Price 1.50 marks.—This brochure discusses the new standard of pure radium which was adopted at the Brussels Radiological Congress and which is in course of preparation by Madame Curie. The work also contains chapters on the measurement of radium emanation, and on the newly discovered thorium products which bid fair to take, at least in part, the rôle of radium in radio-therapeutics. Anyone who desires to learn all that is to be known about radium dosage at first hand, and from the pen of a real authority, cannot do better than consult this short and yet complete work.

Johns Hopkins Hospital Reports. Vol. XVI. Baltimore: The Johns Hopkins Press. 1911. Pp. 670.—The studies of Dr. George Walker on the experimental production of tuberculosis in the genito-urinary organs occupy (including the bibliography) 222 pages. He mentions the following conclusions as points of surgical significance: Tuberculosis in the genito-urinary organs has only two initial points that need be taken into consideration as regards practical surgery—namely, the glomeruli of the kidneys and the tubules of the epididymis. Primary tuberculosis of the bladder never occurs, and primary tuberculosis of the prostate or vesicles is so rare that it may be disregarded. Descent of the disease process from the kidney to the bladder is common, while, though the reverse process may occur, it does so very rarely and only when there is a special involvement around the orifice of the ureter. Tuberculosis may descend from the vesicles and prostate to the epididymis, but ascent from the epididymis to these organs is much more common and is practically the only condition of surgical importance. In another study Dr. Walker investigates the effect on the breeding of rats consequent on the removal of the prostate or the vesiculæ seminales, or both. He finds that excision of both prostate and seminal vesicles renders the male sterile, but neither excision of the vesicles or prostate alone, nor of the vesicles and the prostate, appears to have any effect on capacity for the sexual act or on the structure or function of the testes. Excision of the prostate has no effect on the structure or function of the seminal vesicles. Dr. John Staige Davis writes on scalping accidents. He considers the historical data and anatomic considerations, gives case reports of various groups of scalping accidents, and discusses the symptoms, complications, prognosis, and treatment. He considers that Thiersch grafts give quicker and more lasting results than the small epidermic grafts of Reverdin. He also describes a series of animal experiments. Dr. J. Hall Pleasants deals with obstruction of the inferior vena cava, and reports 18 cases; he also tabulates from the literature 314 cases. The concluding paper is by Dr. Percival Douglas Cameron on Studies of Cardiac Tonicity in Animals.

Talks with Sanatorium Patients. By GILBERT HEATHCOTE, L.R.C.P. & S. Edin., L.F.P.S. Glasg., Medical Officer, Crossley Sanatorium. Manchester: J. E. Cornish, Limited. 1911. Pp. 47. Price 1*s.* 6*d.*—The advantages to patients suffering from pulmonary tuberculosis of residence in a sanatorium are in the main twofold—therapeutical and educational. During the period of treatment the patients are instructed in the mode of life they should adopt after they leave the sanatorium, for certain precautions will have to be taken for a long time after they lose the superintendence of the sanatorium physicians. In the volume now before us Mr. Heathcote explains in popular language the many points which have to be observed so that the benefit initiated by the sanatorium methods may be continued—the diet, clothing, the necessary amount of exercise and rest, and the preventive measures which should be adopted, are all duly discussed, and the remarks should prove useful to those for whom they are intended.

A Monograph of the Anopheline Mosquitoes of India. By S. P. JAMES, M.D. Lond., and W. GLEN LISTON, M.D. Glasg. Second edition, with 15 coloured plates. Calcutta: Thacker, Spink, and Co. 1911. Pp. 128. Price Rs. 16, or 25*s.*—Although this is described as the second edition of a work which we have already noticed in these columns, it has some claims to be regarded as a new work, if only on the technical grounds that the title has been altered from "Anopheles" to "Anopheline." There are also some more and some less important alterations. A few new illustrations have been added in, and interleaved with, the text, while the coloured plates, which are bound at the end of the volume, have been placed in a different order and their legends revised. The authors tell us in the preface that the descriptions of the species have been rewritten. In matters pertaining to science second thoughts are almost always best. And particularly is that the case in relation to a subject which is at the moment in course of extremely active growth. The authors are therefore well advised in giving to us the fruits of their further investigations upon the natural history of these important insects.

Our Baby: For Mothers and Nurses. By Mrs. J. LANGTON-HEWER. Thirteenth edition. Bristol: John Wright and Sons, Limited. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1911. Pp. 176. Price, paper, 1*s.* 6*d.*; leather, 2*s.* 6*d.*—This little book is already so well known to the public, and so few alterations have been introduced into this edition, that words are hardly necessary in commendation of its many merits or in censure of its few delinquencies. As a rule, when individuals who are not medically qualified attempt to deal with strictly medical questions they venture far beyond their depths and become submerged in a sea of difficulties. Mrs. Langton-Hewer, however, has not exposed herself to this reproach. She has not discussed medical matters beyond that point to which as an experienced nurse she is entitled to discuss them, nor would she abrogate to mothers or to the nurse the duties which should be confined to medical men. Her advice on all points of infant management is generally sound, though her attitude towards patent foods is not discriminating, while she shares the common belief of all nurses and all mothers that teething plays a most important part in the minor tragedies of the nursery.

JOURNALS AND MAGAZINES.

Æsculape. Vol. I., No. 8, August, 1911. Paris: A. Rouzaud. Subscription, yearly, 25 francs; single copies, 2 francs.—Among the contents of this number is an interesting article on the pathology of the Aztecs as seen in their votive offerings. Some of the offerings illustrated are distinctly suggestive of the maladies from which their donors had suffered. Another interesting article is that on the Institute of Serum-therapy for Snake-bite at Butamtan, near St. Paul, by Professor S. Pozzi. Dr. G. Encausse gives a brief account of the Aïssaouahs, or followers of Sidi-Ben Aïssa, a species of modern magicians, and of some of their demonstrations. Dr. Paul Rabier-Labiche furnishes an illustrated account of the art work of Dr. P. E. Colin, the physician-engraver. The art museum of Dr. Lannelongue at Castéra-Verduzan is described by Dr. Laurent Poncet. Dr. Auguste Marie, in an article entitled "Some Risks Run by the Medical Profession in Contemporary Society," gives a list of the injuries inflicted on medical men by the mentally unsound. The list begins with the shooting of M. Delpech in 1852, and ends with the wound in the head sustained by Dr. Ameline de Chezal while endeavouring to put down a mutiny in his asylum. Mr. Herbert Ward, Stanley's former companion, contributes a paper on cannibalism.

Man.—The September issue of this journal contains an elaborate article on the characteristics of nine human crania obtained from peat deposits in England and now in the University of Cambridge. Dr. W. L. H. Duckworth and Mr. L. R. Shore, by whom it has been written, have endeavoured to compare these crania with some of the classical palæolithic specimens, and for this purpose have employed four numerical tests—namely, the calvarial height index, the bregmatic angle, the lambda angle, and the breadth indices; the results are shown in a tabular form, and the paper is also illustrated by contour tracings of four of the skulls.

New Inventions.

A SIMPLE APPARATUS FOR THE INTRAVENOUS (OR INTRAMUSCULAR) INJECTION OF SALVARSAN.

THE intravenous method of injection of salvarsan is the best and least painful of all the methods employed, but the forms of apparatus provided for the injection leave much to be desired. The attachment of a long needle direct to the glass nozzle of the syringe introduces a degree of rigidity which is a great disadvantage, if not an actual danger. In introducing a quantity of 200 to 300 c.c. into the vein the syringe requires to be filled many times, and it is practically impossible to prevent considerable movement, with the risk of displacing the point of the needle from the lumen of the vein and the infiltration of the salvarsan solution into the surrounding tissues. The liability of the thin glass nozzle of the syringe to snap off short is a further point of disadvantage. I wish to describe a simple apparatus which is easy to use and free from the foregoing objections. It consists of an all-glass syringe connected to a nickel-plated three-way cock by a short length of 2 to 3 inches of stout indiarubber tubing of medium bore. To the second valve of the stop-cock is fixed about 15 inches of stout indiarubber tubing fitted with a metal attachment sufficient to reach to the bottom of the vessel containing the physiological salt solution or the salvarsan solution. To the third valve of the stop-cock a length of about 12 to 15 inches of rubber tubing is attached. An intravenous needle having a square butt-end which can be clamped flat to the arm by means of an indiarubber band is securely fastened to this tube. A small piece of glass tubing, about an inch in length, is inserted close to its end, so that it can be at once seen, by allowing the blood to

Reproduction of photograph showing method of injection.

flow back, whether the vein is properly entered, or whether, when the injection is being made, the physiological saline solution and the Ehrlich-Hata solution are flowing regularly into the vein The security of the attachment at the various points is ensured by cutting off small bands from the tubing and attaching these over the joint. In this way the connexion between the rubber tubing and the nozzle of the syringe (which is that most likely to become disconnected) is efficiently secured. In using the apparatus the patient should lie with his arm resting close to the edge of the bed, with the solutions, previously warmed by standing in a basin of hot water, placed on a table close to and slightly higher than the couch on which the patient reclines. A tourniquet having been applied, the part is painted with iodine, and a short elastic band, such as is used for holding papers together, is slipped over the arm just above where it is intended to introduce the needle. The syringe and all its parts having been sterilised, the salt solution is drawn up into the syringe and all air expelled from it and from the tubes. With the saline running from the needle, the latter is introduced into the vein, when the blood immediately appears at the glass window; the elastic band is now drawn over the needle, which it holds securely in its place. A little saline is now injected, and the tubing is transferred to the salvarsan solution and the injection is completed. The extra length of tubing attached to the needle enables the operation to be carried out with ease and comfort and without any assistance whatever, and also permits a considerable amount of movement, by either the patient or the surgeon, without the risk of displacing the point of the needle.

Messrs. Squire and Sons, of 413, Oxford-street, London, W., have made me an apparatus of this kind, and they also supply the solution of salvarsan for immediate use.

Brook-street, W. G. W. DAWSON, F.R.C.S. Irel.

A NEW STOMACH CLAMP FOR PYLORECTOMY.

THE essential feature of a stomach clamp for use in the operation of pylorectomy is that it can be relied upon not to slip. Kocher's clamp does not fulfil this requirement, for while the portion of stomach nearest to the hinge—i.e., the greater curvature—is effectively crushed and firmly held, the gastric wall near the lesser curvature is but lightly gripped and tends to slip out of the grasp of the instrument. Messrs. A. Young and Son, Edinburgh, have made for me a clamp which possesses the following advantages:—The blades are slightly curved and very strong, with hog-back to ensure rigidity. The handles are of light construction, being merely for the purpose of applying the clamp and not for crushing. They are connected with the blades in such a manner that the latter always meet parallel (see illustration). The

crushing force is applied by two screws, one at either end of the blades, the one at the distal end being so constructed as to swing up into position after the clamp is applied. When the screws are tightened the stomach is gripped as by a vice, and slipping is not possible.

Edinburgh. D. P. D. WILKIE, M.Ch., F.R.C.S. Edin.

GRESHAM LECTURES, 1911.—Four lectures, on "Flies as Carriers of Disease," will be delivered by Dr. F. M. Sandwith, Gresham Professor of Physic, on Tuesday, Oct. 10th, Wednesday, Oct. 11th, Thursday, Oct. 12th, and Friday, Oct. 13th, at 6 P.M., at the City of London School, Victoria Embankment, E.C. The lectures are free to the public.

INFANTILE MORTALITY AT PORT SAID.—Dr. W. F. C. MacCarthy Morrogh, of the Egyptian Public Health Department, has furnished Mr. Vice-Consul Dunlop with the following report: "There was an increase in the death-rate at Port Said from 27·6 per 1000 in 1909 to 32·4 in 1910. This very considerable rise is due to the terrible infantile mortality. Out of 1444 deaths amongst natives 1068 were of children under five years. This may be accounted for by the ignorance of the parents of the first principles of hygiene, the want of proper care and attention during the early months of life, and improper food; the latter, besides being unfit for children, is often in a state of fermentation, if not putrefaction. There was an epidemic of diphtheria, 82 cases being reported. Here, again, the insanitary habits of the natives, the refusal to accept any preventive measures, and the failure to report cases caused the disease to spread. Most of the houses in the native quarter are built of wood, and it is impossible to keep out the rats which carry the infection. Twenty-eight cases of plague were reported, of which 13 proved fatal. About 17,000 rats were destroyed by the Public Health Department during 1910.'

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 30, 1911.

The National Insurance Bill.

THE autumn session approaches and there are signs already that further debates in the House of Commons upon the provisions of the National Insurance Bill will be keen. Indeed, so widespread in origin and so multifarious in detail has become criticism of the measure that our readers will hardly be considered over-cautious if they begin to take stock of the position in case no legislation follows at once upon Mr. LLOYD GEORGE'S far-reaching proposals. It appears that a good many members of the medical profession share the opinion of a good many members of the public that the Bill, even if it continues to be modified to the same generous extent that has already marked its course during the Committee stage in the House of Commons, cannot prove a well-thought-out measure. Another section of our readers appears to approve of the Bill, though in no very enthusiastic manner, congratulating themselves upon some of the necessary concessions to the medical profession, but viewing other provisions with apprehension; while actual advocates of the Bill among our readers seem to be a very small body. At the same time all enlightened feeling is on the side of a measure which promises so much for the happiness of the existing generation of workers and for the improvement of the health of the next generation. It is in matters of detail and in matters of administration that differences of opinion have manifested themselves to such an extent as possibly to imperil the future of the Bill. As the provisions are more closely looked at by different classes of the population the more do they appear in many directions to want definition. Although at each stage of the debate more or less clearness has been obtained by amendments great and small, there is no doubt that the fact that the measure has shown itself to be so plastic has in itself produced an impression of some distrust. This is well seen in an important letter appealing for the formation of a State service from the pen of Mr. ALBERT BENTHALL, which we print on p. 965 of this issue of THE LANCET. Mr. BENTHALL, whose experience in all matters connected with insurance against sickness and accident is extremely large, finds that the medical profession is taking on trust with far too much readiness the good working of the Local Health Committees, evidently holding that the medical representation on them will not be effective. The dispensing of medical benefits, as far as he can see, need be no better under these committees than it is at present, nor must the position of the medical men of necessity be improved. Mr. BENTHALL'S communication should be read with the attention that it deserves, but we think that his attack on the principle of a free choice of doctor shows an unnecessary distrust of his fellow-men.

Those who believe that the Bill, as far as the clauses which have been debated are concerned, is satisfactory point to two great things—the passing without a dissentient voice of an amendment by the Chancellor of the Exchequer providing for a free choice of doctor by the patient, and the great majority of 387 to 15 by which statutory control of the administration of medical benefits was taken away from the Friendly Societies and placed in the hands of Local Health Committees. The resentment which has been expressed by the Friendly Societies at this logical, and indeed necessary, alteration of the Bill, if the Bill were to be accepted by medical men at all, is, we understand, to have an outcome in a conference between the Chancellor, selected members of the medical profession, and the Friendly Societies. It is an admirable trait in the Chancellor's public policy that he is thus willing to listen to contending views and personally attempt to arrive at just conclusions therefrom; but although there are many points still to be considered in the Bill where such coöperative counsel as is foreshadowed might be valuable, we cannot admit that there is any necessity for debating again the freeing of the medical profession from the control of the Friendly Societies. In proof of this we need only suggest that any of our readers, if there are such, who have any doubt about the advisability of the distribution of medical benefits being removed from the Friendly Societies, should read the proceedings at the meeting of the delegates of the Ancient Order of Foresters at Burton-on-Trent at the beginning of August. An important officer of that association, in protesting against the right of the House of Commons to deprive the Order of the dispensation of medical benefits, described members of the medical profession as sweaters, supporting his words by errors of statement with regard to medical assistants, declaring also that the opposition to the control of the medical benefits remaining in the hands of the Friendly Societies came from men who were envious of those who possessed club practices. This gentleman appeared to think that the old days of the unqualified assistant still existed, and for him the "Battle of the Clubs" has never been fought. Another speaker practically gave it as his opinion that the control of medical benefits was essential to the continuation of the work of the societies, which is going further than anything we have ourselves asserted as to the importance of medical coöperation to these organisations. But we have always believed, and said, that the great inducement which Friendly Societies possess for intending members has been the supply of medical service. From this it would seem to follow that the funds which the Friendly Societies possess, and which command necessarily a good deal of reverence, have had their origin mainly in medical effort. This is the fact which has made the parsimonious treatment by the Friendly Societies of their medical officers particularly ungrateful. A third speaker at the meeting prophesied the formation of Local Health Committees which would be "swamped with doctors," and as a result of these and other lucubrations the Ancient Order formally protested against that amendment of Clause 13 against which in Parliament only 15 dissentient votes were given. From all this it is quite clear that great attempts will

be made to restore Clause 13 to its original wording, but the Chancellor of the Exchequer knows well that if this were done he would run the risk of providing a National Insurance Bill with no medical men to carry on its insurance work.

It supports the idea that the National Insurance Bill has been introduced to some extent at a venture to find that while Mr. BENTHALL sees that the action of the Local Health Committees will be detrimental to the interests of medicine, which profession he feels will be improperly represented upon them, a Friendly Society, representing over a million persons, concludes that these committees will be largely composed of practitioners, or the creatures of practitioners. The cynical might say here that it looked rather as if the Local Health Committees were likely to hit off the happy medium, and form a proper interchange of scientific and public spirit, but men of affairs will consider that they have been given a very strong hint to look closely into the constitution of the Local Health Committees. Similarly, the wide difference of opinion that exists as to how far the German model has been adequately followed leads us to suppose that the Chancellor, despite the anxious pains that he is known to have taken, has not been well-informed as to the position in Germany. Those who have supported the Bill because it was understood that similar legislation has worked extremely well in Germany are beginning to falter in their support of the measure since they have had time to compare the British scheme with the German scheme of insurance. There can be no doubt, as Dr. ERNEST J. SCHUSTER has recently pointed out in a pamphlet,[1] that, while, the German workmen's insurance as a whole may have worked satisfactorily, there is one branch in the conduct of which there has been a good deal of friction; and that is the insurance of temporary sickness. Our readers know well that Dr. SCHUSTER'S words are true. Dr. SCHUSTER suggests that the proposed British system and its uniform rate of contribution for benefits, not even depending upon the wages of the insured persons, is so entirely different from the German system that the success or non-success of the one can hardly be taken to furnish any guidance as to the probabilities of the success or non-success of the other. And now we have before us the remarkable evidence as to the influence upon German industries exercised by the various German insurance schemes, which is contained in the just published report of Sir FRANCIS OPPENHEIMER upon the Trade of Germany in 1910. The position of our National Insurance Bill is certainly an anxious one.

Digitalis in Heart Disease.

WRITING of the use of digitalis in 1778 WITHERING remarked: "It is much easier to write upon a disease than upon a remedy. The former is in the hands of nature, and a faithful observer, with an eye of tolerable judgment, cannot fail to delineate a likeness. The latter will ever be subject to the whims, the inaccuracies, and the blunders of mankind." Few have been better equipped by nature in his own day or since than WILLIAM WITHERING to undertake the task, and his "rules and cautions" for the employment of the drug may be perused with benefit to-day. "Let it be continued until it either acts on the kidneys, the stomach, the pulse, or the bowels; let it be stopped on the first appearance of any of these effects, and I will maintain that the patient will not suffer from its exhibition, nor the practitioner be disappointed in any reasonable expectation." And his last conclusion, "that it has a power over the motion of the heart to a degree yet unobserved in any other medicine, and that this power may be converted to salutary ends," is as true now as when he wrote. He had, moreover, the acumen to add that "If inadvertently the doses of the foxglove should be presented too largely, exhibited too rapidly, or urged to too great a length, the knowledge of a remedy to counteract its effects would be a desirable thing." Such a remedy, he finally remarks, may perhaps in time be discovered, an expectation which has not been disappointed, for atropine largely fulfils these conditions.

Every generation since WITHERING lived has added its quota to our knowledge of the use of digitalis in heart disease, "whimsical," "inaccurate," or "blundering" at times, to use WITHERING'S words, or nearer the truth in other instances and expressed in terms of the current physiology of the period. That, however, which is once true, is always so, although interpretations of the truth, or inferences from it, may vary and be correct or otherwise. It continues true, as WITHERING maintained, that digitalis has "a power over the motion of the heart," which the observation and skill of many have "converted to salutary ends." Opinion has, however, naturally varied with experience as to the circumstances and manner in which this powerful agent has proved most beneficial, and even after the lapse of more than a century our ideas lack precision in the matter. In the conclusions reached *individual* experience often proves to have played too large a part and to have obscured rational generalisation. It is recognised, however, that digitalis is impotent to influence heart-rate in the presence of febrile stimulation, and we now know the importance of determining the presence or absence of an infective endocarditis in the case of old disturbed lesions, even when the febrile movement is mild and intermittent. Extrinsic conditions, such as thyroidism and pericardial tethering, we also know may render futile the potential power for good of the drug. Authorities, again, in all probability have differed through attaching too great importance to personal experience, as to the value of the drug in the case of particular lesions. Thus the agent decried by CORRIGAN in aortic cases was extolled by BALFOUR as powerful for good when the same defect was present, while BROADBENT split the difference and indicated its utility in such cases when "mitral symptoms" supervened. This, however, was little more than to acknowledge that an aortic case had broken down, and the majority of observers still attach more importance to cardiac failure in such than in purely mitral cases, because experience has shown the former to be more difficult of remedy. Sir WILLIAM

[1] The Parliamentary Bill Examined and Compared with the German Scheme (reprinted from the Journal of Comparative Legislation), by Ernest J. Schuster, LL.D. London: John Murray and Co. 1911. Price 6d.

BROADBENT also maintained that while mitral regurgitant cases "almost always" benefited from the use of cardiac tonics, this was by no means equally so in mitral stenosis.

It seems, however, to have been generally agreed in the past that digitalis has found its most striking successes in uncomplicated mitral regurgitation associated with the general evidence of cardiac failure, on whatever lines it has been sought to explain this fact. In these circumstances of still existent uncertainty on many important points, every carefully considered record of experience in the use of the drug is worthy of note, and such a contribution appears in the last issue of *Heart*, which is wholly occupied by an article on digitalis from the pen of Dr. JAMES MACKENZIE. After an introductory generalisation as to the efficacy, or want of efficacy, of the drug in certain circumstances, he gives a detailed account of 40 cases in which the dosage and effects of the drug were carefully noted, and certain conclusions or impressions are finally expressed. Of his 40 cases no less than 20 had mitral stenosis or were diagnosed as such, one is described as "mitral," ten as "mitral and aortic disease," two as "aortic," and the remaining seven constituted a miscellaneous group containing cases of paroxysmal tachycardia, bradycardia, and emphysema. Of the mitral stenotic cases ten responded well to digitalis and eight apparently did not; of the mitral and aortic, only one seems to have answered definitely to the remedy. One of the stenotic cases could scarcely have been expected to show definite results, as it was evidently one of infective endocarditis, although the fact is not mentioned in the record, and had, of course, a fatal issue. Of the two aortic cases neither was notably affected by the drug, while in the miscellaneous group four improved under digitalis and three did not. It is not the amount of material here set forth, but the care with which the investigation was carried out which renders it worthy of consideration. The language employed by Dr. MACKENZIE is largely that of the new cardiology in which the auriculo-ventricular bundle and the various possible starting places for cardiac contraction and fibrillation of the auricle play a part, although he does not fail to ascribe a considerable rôle to the action of digitalis upon the vagus in modifying the action of the heart.

The general conclusions arrived at are, that "Cases of auricular fibrillation are more readily and markedly affected than cases with the normal rhythm." In other words, that the irregular heart, and particularly that explosively and often temporarily irregular heart which is usually associated with mitral disease, especially in younger subjects who have suffered from rheumatic fever and in whom the cardiac muscle is fairly sound, respond most easily to the drug. It is admitted that in persistent irregularities and in older people it is less successful. Dr. MACKENZIE suggests that the fibrillating auricle may render the auriculo-ventricular bundle more susceptible to the action of digitalis, which, by impeding the shower of auricular impulses regarded as falling upon the ventricle, may induce calm. Digitalis, however, it is contended, at times tends to *produce* auricular fibrillation. Some evidence is adduced that the diuretic effects of digitalis may be observed without any perceptible change in the heart, and two cases of tachycardia "arising from an abnormal source" are mentioned in which a more normal rate was established after the occurrence of fibrillation of the auricle.

The preparation of digitalis chiefly used was the tincture, and it was given in doses of 15 or 20 minims three or four times a day "until some definite reaction was obtained" of the kind indicated by WITHERING. The principle of pushing the drug, as experience has taught many, is frequently necessary to attaining success, but, while not averse from a guarded boldness in the use of digitalis, we own to a conviction that slow increase in dosage is usually quite effectual when remedy is possible by this means, and that the comparatively rapid induction of nausea or vomiting is rarely necessary and not always safe. Incidentally, Dr. MACKENZIE mentions some interesting observations on the inefficacy of some and the efficacy of other agents which have been employed in the treatment of heart disease. Thus he found aconite, long regarded as a retardant of cardiac action, to be quite inert in medicinal doses. Although he found strophanthus acted well in regulating irregular hearts, he never observed it to succeed where digitalis had failed. Atropine, he convinced himself, was potent in accelerating some hearts retarded by the action of digitalis. It will thus be noted that Dr. MACKENZIE'S experience of the use of digitalis in heart disease differs little from that of many others who have recorded their observations. Yet we fully recognise his painstaking endeavour to secure trustworthy data for the formation of more precise and scientific opinion on the use of a drug which is still used by many empirically, and which, like most agents capable of effecting good, requires to be employed with all the circumspection possible.

Annotations.

"Ne quid nimis."

CERTIFICATE OF PROFICIENCY IN VACCINATION.

THE Local Government Board has issued a circular dated Sept. 21st, 1911, with reference to the certificate of proficiency in vaccination which is required to be produced by a medical practitioner to a board of guardians before he can enter into a contract with them for public vaccination. A certificate of proficiency in vaccination can in general only be obtained from a teacher authorised by the Board after due instruction and examination. The Order of 1905, however, permitted certificates of proficiency to be given to certain classes of medical men after examination only and without a previous course of instruction. The present Order extends the exemption from the course of instruction prior to examination to any person already holding a medical diploma or degree granted in a British possession or foreign country who is a candidate for examination by an examining body in the United Kingdom for a diploma, licence, or degree conferring the right of registration under the Medical Acts. The new Order supersedes the Order of 1905 and incorporates its provisions. The following teachers and examiners are entitled to give such certificates of proficiency

in vaccination (to the special classes of medical men defined in the Order) after examination only, and without a preliminary course of instruction:—

STATION.	NAME OF VACCINATOR WITH ADDRESS.
London—Tolmers Square Institute, Drummond-street, N.W.	Mr. Joseph Loane, 13, Great Alie-street, E.
Bristol—St. Peter's Hospital, Bristol...	Mr. George Shepley Page, 78, Old Market-street, Bristol.
Liverpool—17, Mulgrave-street ...	Mr. Nathaniel Edward Roberts, 17, Mulgrave-street, Liverpool.
Newcastle-upon-Tyne—The Dispensary, Nelson-street...	Dr. Frank Hawthorn, 6, Regent-terrace, Newcastle-upon-Tyne.
Edinburgh—The Western Dispensary, St. Cuthbert's Hall, Riego-street, Tollcross	Dr. John Brown Buist, 1, Clifton-terrace, Edinburgh.
Dublin—45, Upper Sackville-street	Dr. Alexander Nixon Montgomery, 45, Upper Sackville-street, Dublin.

A practitioner who has obtained a certificate of proficiency in vaccination granted by a teacher authorised for the purpose by the Board as a condition of obtaining a diploma, licence, or degree is not required to produce it before entering into a contract with a board of guardians for public vaccination. The Order will be placed on sale, so that further copies may be obtained from Messrs. Wyman and Sons, Limited, Fetter-lane, E.C., either directly or through any bookseller.

COW-DUNG FLOORS AND PLAGUE PREVENTION.

FROM a medical correspondent possessing an intimate knowledge of the social and religious life of the natives of India, and a close acquaintance with their habits and customs, we have received an interesting communication in which he endeavours to prove that the comparative immunity from plague experienced by Madras and Eastern Bengal is due to their methods of practising domestic hygiene, and particularly to their carrying out the very ancient custom of frequent spreading or washing of floors with cow-dung. He points out that, on the other hand, in the Punjab and other northern and north-western provinces which have been, and still are, suffering severely from the ravages of plague, and which are, as he expresses it, "too highly Mahomedanised," this spreading of cow-dung on the floors has been neglected, the people having abandoned largely this old Hindu practice handed down to them by their forefathers. There is no doubt a religious side to this question, and for that reason we hesitate to express ourselves as freely as we otherwise might have done. But our remarks are made strictly from the sanitary point of view. We understand our correspondent's view to be that this dung treatment of floors acts in two ways:—firstly, there is a slight chemical action upon organisms which may be present on the floor; secondly and mainly, the mechanical effect is to entangle in the semi-liquid dung and thus destroy any fleas or flea-eggs. We think, however, that sprinkling the floor with a weak solution of some disinfectant, accompanied with frequent vigorous sweeping, would effect more benefit, especially if the floor were made smooth and impervious by cement or in other ways. There is also another consideration to be kept in mind—namely, that tubercle bacilli may be present in the cow-dung, and that these might in one or another way infect the inmates of the dwelling. Our correspondent argues that the ancient method of "cleansing" floors is well known to all classes of the inhabitants of India, and that its adoption could be more easily enforced than could any other procedures suggested by sanitarians. We are, however, of opinion that as a plague-preventive measure this use of cow-dung has nothing to commend it. The first Indian Commission showed by experiments that B. pestis can live in sterilised cow-dung for several weeks, or even months, though in unsterilised dung the microbe did not survive longer than six days. That cow-dung has little effect in preventing the multiplication of fleas has been proved by the Advisory Committee for the Investigation of Plague in India, one of whose prominent members, Dr. C. J. Martin, director of the Lister Institute, has made the following statement in one of his reports: "The Indian hut, with its floors of cow-dung and its indescribable litter, in addition to providing cover for rats to nest, affords good breeding ground for fleas of all sorts. The amount of vermin infestation of these houses may be gathered from the fact that in one room in which dead rats had been found and plague cases had occurred the Commission for the Investigation of Plague in India secured 263 fleas." Cleanliness of persons and of house interiors, with admission of sunlight and fresh air, will do more to prevent plague in Hindu huts than the spreading of cow-dung on the floors. It is well known that the vitality of B. pestis is quickly acted upon by exposure to the rays of the sun or to the effects of drying, as, for example, by a current of air.

INJURY OF THE SPINE DUE TO MUSCULAR EFFORT.

IT does not appear to be generally known that serious, and even fatal, injury of the spine may be a result of muscular effort. In the *Glasgow Medical Journal* for July Dr. George S. Middleton and Dr. John H. Teacher have reported a remarkable case of rupture of an intervertebral disc. An engineer's labourer, aged 38 years, was admitted into the Glasgow Royal Infirmary on Feb. 12th, 1910. At 6.30 A.M. on the 8th, while lifting with another man a heavy plate from the floor to a bench 3 ft. high he "felt something crack in his back." He could not stand up straight, but had to remain bent on account of pain and a feeling of weakness in the back. For a quarter of an hour he tried "to straighten himself" and then walked home—a distance of two or three minutes—in a bent position. He said that he had often lifted heavier weights before without injury, and the man who assisted him did not suffer in any way. When he reached home he sat in a chair fairly comfortable, but movement caused intense pain, radiating from the back round both sides. He was seen about 1 P.M. by his medical attendant, who ordered him to bed. He was able to walk to the bed, but could not stand, his legs giving way. He attributed the difficulty to excruciating pain in the back. In bed he was most uncomfortable, turning and twisting to find a comfortable position and suffering much pain in the attempts. He felt sick, but did not vomit. On that night he micturated for the last time. Between 2 and 3 A.M. he felt an agonising pain shoot down from his chest to his feet with peculiar sensations as if his limbs were "sleeping." This soon passed away, and he found that he could not move either leg. The bladder and bowels became paralysed and on Feb. 12th he was sent to hospital as a case of intestinal obstruction. In the ambulance van his bowels acted without his knowledge. On admission there was great distension of the intestines and bladder and complete flaccid paralysis of both legs with anæsthesia as high as Poupart's ligaments. The cremasteric and all the reflexes of the lower limbs were absent. Both legs became atrophied in their whole length, including the glutei. At the upper part of the buttocks two acute decubital sores formed. He grew steadily weaker, the urinary sepsis increased, the temperature rose, rigors occurred, and he died on Feb. 24th. At the necropsy no irregularity of the spine could be made out either externally or after opening the canal. There was no clot outside the dura mater. There was marked softening of the lumbar enlargement of the cord with brown staining indicative of hæmorrhage, but there were no clots. There were also early hypostatic pneumonia at the left base, septic cystitis, pyelitis, and

abscesses in the kidneys. After hardening in formalin the cord showed much blood in streaks through several segments of the lumbar enlargement. A segment about a quarter of an inch long was thinner than the rest and appeared to have been crushed. Opposite this, entangled in the loose fibrous tissues outside the dura mater, was an irregular circular flat mass of firm white tissue which looked like the pulp of the centre of an intervertebral disc. Microscopic examination showed the characteristic structure of this pulp. The mass was 15 millimetres in diameter and 5 thick. Its margins were ragged; a few red blood corpuscles adhered to them entangled in the shreds. Microscopic examination of the cord showed advanced softening amounting almost to necrosis in the central parts and much diffuse blood infiltration extending above and below the crushed segment. There was early secondary degeneration of the various tracts. Unfortunately, the portion of the intervertebral disc was not noticed until the day after the necropsy, when further examination of the spine was impossible. But injury or displacement of the vertebræ of the common types had been searched for and could be excluded. From the position of the injury of the cord it seemed that the disc which gave way was that between the twelfth dorsal and first lumbar vertebræ. When the injury took place the back must have been bent with the lumbar and abdominal muscles in full action. This would powerfully compress the intervertebral discs with the anterior margins of the vertebræ approximated—a favourable position for displacement of the pulp of the intervertebral disc backwards. A case presenting some similarity in respect to injury of an intervertebral disc has been recorded by Kocher. A man fell 100 feet and sustained various injuries, including rupture of the bowel, from which he died in some hours. The disc between first and second lumbar vertebræ was smashed and squeezed out from between the bodies, which appeared to be undamaged. Both cases show the possibility of injury to the intervertebral disc without visible injury to the vertebræ.

THE PREVENTION OF MALARIA IN ATHENS.

THE name of the Athenian Ilissus awakens in many of us ideas of beautiful scenery. Images are evoked by its name such as succeed in our minds at the mention of the streams of Yarrow, Thames, or Liris. Consequently it is a shock to find the Ilissus accused of causing the malaria which has long hung about Athens. That is the charge brought against it by Professor Cardamatis of Athens, who has explained in the *Archiv für Schiffs- und Tropen-Hygiene* for August how he has freed the Ilissus from this disgrace. As he says, there are two conditions required for the spread of malaria: patients there must be, infected and infective, as well as mosquitoes to carry the infection; remove one or other of these factors and the malaria ceases. Either, that is, cure the patients by the administration of quinine, or get rid of the breeding places of the anopheles, or combine both methods. Professor Cardamatis reports that New Anchialos was freed from malaria by quinine, while at Marathon he and a colleague got rid of it by quinine and improved drainage. In Athens the controlled treatment of all individuals by quinine was impossible, so he attacked the state of the Ilissus, a sluggish stream which spreads itself into many wide shallow semi-stagnant pools, the very places for mosquito larvæ, further sheltered as these are by the weeds which grow in the slow-moving water. He cleaned the river bed, by embankments and deepenings narrowed its course and expedited its flow, and he has the new bed swept out every week to get rid of anopheles' eggs which may have become deposited. These works were begun in 1906. In the years 1901–1905 inclusive the children of the neighbouring schools found to be infected with malaria had averaged 80 per cent. The number at once began to fall, and in 1906 and subsequently the proportions found infected were successively, per cent., 60, 21, 2⅔, ⅔, and none. Thus the course of the Ilissus has been freed from malaria, and Professor Cardamatis deserves credit from every lover of Ancient or Modern Greece and from every sanitarian for the striking improvement he has secured by measures so simple and so sagacious.

BEER AS A CONDIMENT.

ALTHOUGH beer does not contain a large amount of nutrient material there appears to be little doubt that in the healthy individual it favours the assimilation of food in a manner akin to such condimental substances as meat extract, pepper, salt, vinegar, mustard, and so forth. Recent investigations on this point at all events show that malt extractives contained in beer, added to a dietary almost devoid of organic condiments, increase the assimilation of non-nitrogenous food-stuffs, particularly fats. In addition 86 per cent. of the extractives of beer themselves are assimilated and yield about 81 per cent. of their thermal energy to the system. Beer supplies, however, a negligible amount of proteins, but the stimulus of its alcohol increases protein absorption from nitrogenous foods. In these scientific terms, therefore, the practical observation that beer, bread, and cheese make an appetising nutritious whole receives definite endorsement. Physiologists have put forward from time to time various explanations of the fulness and plethora which often succeed the habitual and excessive drinking of beer—it is strikingly exemplified in the brewer's man—and it now appears that this effect is not due to the nutritives of the beer, but to the tonic or condimental action of the malt extractives, which increase the assimilation of the foodstuffs partaken with it. Some valuable scientific contributions upon this and related subjects appear from time to time in the *Journal of the Institute of Brewing*, in which will be found the reports of the International Physiological Research Institute founded for the purpose of carrying out investigations on the physiological effects of beer and other alcoholic beverages. These researches will be welcomed as calculated to throw light upon the hygienic aspects of the national beverage.

SCARLET RED AS A STIMULANT TO THE EPITHELIATION OF GRANULATING SURFACES.

IN 1906 B. Fischer drew attention to the remarkable growth of epithelium produced by the subcutaneous injection of a saturated solution of the dye known as scarlet red in olive oil into the rabbit's ear, and suggested therapeutic possibilities. His experiments have been confirmed and extended by a number of investigators. Schmieden first adopted his suggestion and in 1908 reported rapid healing of sluggish ulcers. He used an 8 per cent. ointment and alternated it every 24 hours with some bland ointment on account of the irritating properties of the scarlet red. He insisted that the granulations must be perfectly clean and flat, and that it was useless to apply the ointment to an unclean ulcer. Kaehler modified Schmieden's technique and obtained good results in unhealthy granulating wounds. Krajea then used scarlet red in conjunction with partial Thiersch grafts and found that their edges, as well as those of the wound, were stimulated. In the *Johns Hopkins Hospital Bulletin* for June, 1909, Dr. John Staige Davis reported 60 cases in which he had used scarlet red with satisfactory results, and in the number for June, 1911, he has returned to the subject. Carrel, the well-known American surgeon, states that when at the end of the period of "granulous retraction" of a large wound the edges of

the old epidermis are still at a distance of 20 to 25 millimetres the new epidermis cannot spread on the granulations and cicatrisation comes to a standstill. In almost all the wounds treated by Dr. Davis "granulous retraction" had long ceased, epidermisation had come to a standstill, and the areas were for the most part very large. Nevertheless, marked epitheliation took place from the once sluggish edges, and subsequent rapid healing. Several chemically different dyes are sold under the name of scarlet red, of which Dr. Davis has used three. He has obtained the best results from toluene-azotoluene-β naphthol. He obtained marked epithelial stimulation even when the wounds were unhealthy and the discharge profuse, but the most rapid results were obtained in flat healthy granulating surfaces. His technique is as follows. Cleanse the wound thoroughly with boric or salice solution and dry. Peroxide of hydrogen may be used before the boric solution if the granulations are unhealthy. Nitrate of silver stick is freely used to keep down exuberant granulations. Tincture of iodine (U.S.P.) may follow the silver or be used on alternate days and is a powerful and rapid cleanser of granulations. The scarlet red ointment is usually of 8 per cent. strength, and it is alternated every 24 or 48 hours with some bland ointment. The ointment is applied as follows. Anoint the skin around the defect with some bland ointment to within 1 centimetre of the wound, to prevent irritation. Spread the scarlet red ointment on a thin layer of perforated old linen and apply to the wound either along the edges or over the whole surface. A light dressing of sterile gauze completes the procedure. A 4 per cent. ointment may be used on partial skin grafts of all kinds and causes rapid growth of epithelium from the wound edges and the grafts. Dr. Davis has also used with equally good results amido-azotoluol, a component of scarlet red. Some writers have gone so far as to claim that by the use of these substances skin-grafting can be abolished. Dr. Davis thinks that this is claiming too much, but he has no doubt that wounds can be healed which otherwise could be closed only by grafting. The skin produced is stable and resistant, and of normal appearance macro- and microscopically. There is no tendency to subsequent contraction, and the skin becomes moveable on the underlying tissues.

THE DANGERS OF BRIQUETTE MANUFACTURE.

LAST year the Secretary of State certified the manufacture of patent fuel (briquettes) with addition of pitch to be dangerous, and draft regulations were issued which it was proposed to apply to this industry in pursuance of Section 79 of the Factory and Workshop Act, 1901. Objections were subsequently received by the Secretary of State, who thereupon directed an inquiry to be made. For this purpose Mr. Alfred Herbert Lush, barrister-at-law, was appointed, and his report has just been issued. On the whole, he concludes that the industry is not an unhealthy one—in many respects, indeed, it is said to be exceptionally healthy. But there are two elements of danger, he adds, due to the action of pitch fragments or dust on the eyes and of pitch dust on the skin. The dust induces chronic changes in the corneal and sclerotic coats of the eye, and wounds are sometimes inflicted by flying fragments during digging or breaking pitch which are difficult to heal, and impaired sight or even blindness frequently follows. The so-called pitch warts form on the body after a considerable period of working in the briquette factory. Usually these warts are not malignant in character, save when they occur in particular parts of the body—the lips or genital organs, and more especially the scrotum—producing that scrotal epithelioma which, though a rare disease amongst the general population, is frequent amongst chimney-sweeps who are exposed to soot in the same way as are fuel-workers to pitch dust. Remedies are proposed in the draft regulations which include the prevention of dust, the wearing of overalls and goggles, and frequent washing. It has been agreed to institute trials in order to find out the practicability of applying the suggested regulations. Meantime it seems desirable to attack the question as to what is the harmful substance in pitch with the view of eliminating it.

HOSPITAL FINANCE IN LONDON.

THE statistical report on the ordinary expenditure of London hospitals for the year 1910, which has recently been issued by King Edward's Hospital Fund for London, is a very interesting document. Statistics relating to 106 institutions are dealt with in the report, the first section of which consists of an alphabetical series of tables giving general statistical particulars, total expenditure, cost per bed occupied, and per out-patient attendance. The other sections of the report analyse in detail the expenditure of such of the hospitals as can be conveniently grouped together. As pointed out in a prefatory note, it can hardly be expected that the hospitals, whose expenditure has now been analysed for several years, should show further reductions in cost on the same scale as those which followed the issue of the first report. The fact, however, that the report for 1910 shows a saving of £2000 over the previous year's economies, in spite of the development of new methods of treatment and the sustained rise in prices, speaks well for the way in which the hospitals of the metropolis are managed. In 1905 economical methods effected a saving of £21,000 in the case of 16 hospitals; and in 1906 48 hospitals showed an additional saving of £18,000. In the following period a change was made in the keeping of hospital accounts, and comparisons were impossible till 1908–09, when a further saving of £6000 was shown by 55 hospitals. The document, which can be obtained from Messrs. Spottiswoode and Co., Limited, 5, New Street-square, London, E.C., is published at 1s. net, or 1s. 3d. post free.

THE DANGERS OF INTRAVENOUS INJECTION OF ALKALINE SOLUTIONS.

THE use of large doses of carbonate of soda and other alkalies in the treatment of various forms of acidosis, and especially that of diabetic coma, is a well-established practice; but it appears from the experiences of Dr. Léon Blum, published in *Semaine Médicale* of Sept. 13th, that there is a limit to the safety of this measure, especially when the intravenous method of administration is used. One of the cases described by him will serve as an illustration of certain untoward effects, which are apparently to be ascribed to the toxic action of sodium. The patient, a woman, 34 years of age, was in an early stage of diabetic coma, and it was decided to administer sodium carbonate intravenously. A 5 per cent. solution was used, and a vein on the bend of the left arm was exposed and the cannula introduced. After a few drops of the solution had been poured into this vein it swelled up for a distance of six centimetres, and no further fluid could be induced to run in. The injection seemed to be painful. A further attempt was made with another vein of the same arm, but with an equally unsatisfactory result, and the skin and subcutaneous tissues in immediate relation with both veins became discoloured by infiltration with blood. The cephalic vein of the right arm was next used; here, however, the same phenomena were repeated, the vein swelling to the size of the little finger as far as the axilla. By means of massage of this vein it was possible to introduce 750 cubic centimetres of the solution, though with difficulty and at the cost of giving the patient evident pain. Almost immediately after the injection was

completed the state of somnolence which had served as the chief indication for its use deepened into coma, and both pulse and respiration became feeble. Between this and death, which followed about four hours later, there were several severe attacks of clonic convulsions. A post-mortem examination disclosed no gross injury of the central nervous system; the veins of the left arm were normal, while that in the right arm was filled with clot, though there was apparently no phlebitis. Blum produces various experimental and clinical facts which are in accord with this experience, and go to prove that alkaline solutions, if of too great a strength, are capable of producing venous spasm and various evidences of central nervous poisoning. Convulsions, which have been described as occurring with the very greatest rarity in diabetic coma, are especially related to the injection of these solutions, so that there is little room for doubt as to their causation. Blum believes that it is the sodium of the salt that is toxic, for various ill-effects have been noted after the injection of so innocuous a compound as the chloride. Unhappily, as he points out, it is not so easy to balance the effect of sodium in alkaline injections as in those designed for the introduction of the neutral chloride; in the latter potassium and calcium chlorides are added to the sodium salt, but in the former the use of calcium, at least, is precluded by the formation of insoluble calcium carbonate. In default of such a plan Blum recommends the use of bicarbonate of soda in a 6 per cent. solution. This should be boiled for a quarter of an hour, not only to sterilise the solution, but also to render it less toxic by converting the bicarbonate into the carbonate of soda.

THE BACILLUS COLI AND PLANT DISEASES.

AN interesting inquiry has been undertaken by Mr. John R. Johnston, for the Laboratory of Plant Pathology, United States Department of Agriculture, as to the relation between bacillus coli and certain plant diseases. The inquiry arose in this way. In August, 1909, two different cocoanut trees in Cuba were found to be very seriously affected with bud-rot. Certain bacterial organisms were isolated therefrom and seven apparently healthy trees were inoculated with the cultures. In about three weeks a soft white rot, typical of bud-rot disease, was found in each case. Isolations made from these artificially diseased trees were then sent to Washington for study. Four of these, from different trees, were inoculated into four cocoanut seedlings, and typical soft rots resulted. Isolations were again made from these rotted tissues and further inoculations were practised, with similar results, the organisms recovered being the same as those found in the first artificially infected trees. It thus seemed as though at least one organism capable of causing the bud-rot of the cocoanut palm had been identified. Examination of this organism showed that its cultural characters corresponded to those of the bacillus coli, so that the principal means of identifying the bacillus coli were applied to the cocoanut organism, and the two organisms were subjected to a close comparison in great detail, with the result that "it was found impossible to ascertain any characters by which the cocoanut organism could be distinguished from the bacillus coli received from the animal pathological laboratories.' The converse experiment was then made, and it is this that forms the subject of Mr. Johnston's paper.[1] Cultures of bacillus coli of animal origin, obtained from different laboratory sources, were inoculated on different occasions into the heart tissues of 11 cocoanut seedlings about 1 metre high in a greenhouse in Washington, three other seedlings receiving a plain inoculation as checks. In every instance the result was a water-soaked area about the inoculation hole, and in three cases also a soft-rotted area. The checks, however, showed neither water-soaked nor rotted area. Inoculations of bacillus coli were next made into three cocoanut trees in Cuba and infected the trees, producing brown, wet-rotted areas. Ten subsequent inoculations into seedlings in a greenhouse showed browning of tissues in six cases, two showed good brown rots, one a typical soft wet rot and a brown stain, and one a wet rot. Bacillus coli was recovered from six of the first batch of seedlings inoculated, and from each of the three trees; no platings were made from the second batch of seedling inoculations. The identification of the bacillus coli was in each case made by all the usual methods. Mr. Johnston concludes that the finding of very closely allied forms in the many cultures made, together with the presence of a form indistinguishable from bacillus coli, indicates a probable greater importance of this organism in relation to the vegetable world than has heretofore been recognised. Comparative pathology, even among different members of the animal kingdom, is a science of comparatively recent growth. Its extension to the correlation of animal and vegetable pathology may open up unsuspected factors in etiology

[1] Is Bacillus Coli a Plant Parasite? By John R. Johnston. Phytopathology, vol. i., No. 3. June, 1911.

AN ALLEGED MURDEROUS ASSAULT EXPLAINED AWAY.

MEDICAL evidence and the fact that corroboration of her story was not forthcoming proved fairly conclusively, at a recent inquest held at Chelsea, that an account given of certain injuries by a lady residing in a flat in Park Walk, S.W., was the outcome of delusions on her part. Miss Ada Solly Flood, 54 years of age, was found by her servant, who had been out from 3.30 to 11.30 P.M., to be suffering from cuts on her head, and to her, as well as in a letter to her medical attendant, Miss Flood told a story of two men wearing motoring caps who came to the door of her flat, which she opened. According to her, one of them then struck her on the head with a weapon, and when she came to her senses she found that a purse containing money had been stolen from her flat. The police made inquiries, but could not find any trace of the flat having been invaded as described, and the manager of the establishment gave evidence at the inquest to the effect that he believed it was impossible that the alleged incident could have taken place. It was stated, however, by the servant that a purse had in fact disappeared. Miss Flood after the evening in question became very ill and was medically attended, dying three days after the supposed attack upon her. A cousin deposed at the inquest that she suffered from hallucinations, and the evidence of her servant left no doubt that she was an alcoholic subject. The medical evidence was to the effect that the injuries of the deceased might have been due to a fall, and that death was from heart failure and had been accelerated by alcoholic excess. The jury gave a verdict accordingly, saying nothing as to the alleged assault. Such cases as these are not uncommon in the records of forensic medicine, and sometimes put the equipment of the medical practitioners consulted to a severe test. It is not difficult to see that in analogous circumstances there might be considerable risk of a miscarriage of justice.

INCORPORATED ASSOCIATION OF MEDICAL OFFICERS.—The following are the principal papers announced to be read during the ensuing session of the Association of Medical Officers which opens on Friday, Oct. 20th: Mr. H. C. Barker, superintendent of the out-patient department of the London Hospital, on "Medical Treatment of London County Council School Children"; Mr. Godfrey Hamilton, secretary of the National Hospital for the Paralysed and Epileptic, on "Hospital Appeals"; and Mr. L. H. Glenton Kerr, secretary of the Great Northern Hospital, on "Paying Hospitals of the Future."

ASYLUM REPORTS.

Down District Lunatic Asylum, Downpatrick (Annual Report for the Year 1910).—At this asylum the daily average number resident was 753. The admissions numbered 133, being 14 less than the number admitted the previous year. Of these, 103 were first admissions and 30 readmissions. The discharges numbered 70, and of this number 65 were recovered; the recovery-rate on the admissions stands at 48·9 per cent. Deaths numbered 54, being a rate of 7·2 of the daily average number resident. The deaths are registered as due to heart lesions in 20 cases, to phthisis and other tuberculous affections in 17 cases, to pneumonia in five cases, and to general paralysis, organic brain disease, and liver disease in two cases each. Mr. M. J. Nolan, medical superintendent, remarks that the Inspectors of Lunatics in their fifty-ninth report lament that the county councils have failed to avail themselves of statutory provisions "by which a common laboratory might be provided and a pathologist appointed." He fears that the subject is one which is so removed from the trend of county affairs that it will remain a dead-letter so long as the provisions are optional. He points out that though special rates are levied for a variety of purposes of questionable utility, some at least of which are either sentimental or intangible, yet that in Ireland no organised effort scientifically to investigate the causes of the burden of insanity is made.

Joint Counties Asylum, Carmarthen (Annual Report for the Year 1910).—The average daily number resident was 680. There were admitted during the year 109 patients. Of the admissions the attack occurred for the first time in 64 cases, and of these 35 were admitted within three months of the onset of the mental disorder, and therefore constituted the most favourable group for treatment; 38 cases showed symptoms of mental disorder, about which little or no hope of recovery could be entertained from the first. In 16·7 per cent. of the admissions (excluding statutory readmissions) there was ascertained a history of hereditary insanity or allied disorders. Mental stress, sudden or prolonged, was attributed as an etiological factor in 43 cases; while alcoholism was assigned either as an exciting or a predisposing cause in 13 cases, or 12 per cent. of the total admissions. There were 43 discharges, and of these 27 were recovered. Of the cases discharged recovered 10 were in residence from one to three months; 9 from three to six months; 3 from six to nine months; 1 from nine to 12 months; 2 from one year to two years; and 2 from two to three years, the average duration of residence being seven months, and the average age of the patients 39 years. The deaths numbered 54, and necropsies were performed in 41 cases. Tuberculosis still figures highly as a cause of death, but it is satisfactory to know that the proportion per cent. of tuberculosis deaths in all cases, namely 18·5, in the past year is the lowest recorded for 12 years, and that it has shown a steady decline since 1906, when the rate at this asylum was 38·9. One male patient died from senile decay at the advanced age of 106. An interesting point in his case was the fact that he had not lost a single tooth during life.

Kent County Lunatic Asylum at Barming Heath (Annual Report for the Year 1910).—The average daily number on the registers was 1627. There were admitted 405 patients; 15·3 per cent. of the direct admissions were over 60 years of age. 66·6 per cent. of the patients had been ill for more than a month previous to admission. Of the direct admissions, 27·5 per cent. had previously been discharged recovered, this being rather a lower percentage than usual. Dr. H. Wolseley-Lewis, medical superintendent, points out that this high rate means that there are a number of unstable people who, under the ordinary stress of life, break down mentally, and that, unfortunately, this mental instability is a quality likely to be transmitted to their offspring should they have any. In 50·9 per cent. of the admissions hereditary defect was ascertained. The discharges numbered 183, of whom 132 were recovered. 65·1 per cent. of the recoveries took place within a year from the commencement of the attack; 50 per cent. of those discharged recovered had a neurasthenic history, and in 65·1 per cent. the form of disease from which recovery took place was either recent melancholia or recent mania. There died 207 patients, being a percentage of 12·7 on the average daily number on the registers. In 85 per cent. of the deaths necropsies were performed. The chief causes of death were phthisis, 17·3 per cent.; morbus cordis, 16·4 per cent.; general paralysis, 13·5 per cent.; senile decay, 11·1 per cent.; and dysentery, 5·3 per cent. Of the 1629 patients who remained in the asylum on Dec. 31st, 1483 were considered quite incurable.

Kent County Lunatic Asylum, Chartham Downs, Canterbury (Annual Report for the Year 1910).—At this asylum the average daily number on the registers was 1014. There were admitted during the year 224 patients. There were discharged 99 patients, of whom 72 were recovered, being a rate of 32 per cent. on the total number of admissions. The deaths numbered 135, being 17 less than the previous year.

Public Health.

REPORTS OF SCHOOL MEDICAL OFFICERS.

County of Rutland.—Dr. Christopher Rolleston in his report details the method of medical inspection and the steps taken to ensure the coöperation of the parents; the routine is somewhat elaborate. As a rule, not more than 24 children are examined in any one day, and ten minutes are taken for each case, weighing, measuring, and vision-testing being done by the medical officer. A letter of notification is sent to the parent by post from the education office, and the exact time at which the child will be inspected is stated on a gum slip affixed to the letter. The time of the parent is thus saved and also the inconvenience caused by a crowd of waiting parents. The ordinary schedule of the Board of Education is followed, but in addition the method of feeding and upbringing in infancy and early youth is inquired into, and also the age at which the child began to talk and walk. The name of the family medical man is ascertained, and any defects revealed are notified to him by letter at the close of the examination. At the expiration of three months the school medical officer pays a return visit and re-inspects the children found defective at the previous examination; if the children have not been treated a second letter is then written to the parents urging them to get advice, and asking them if they have any difficulty in obtaining treatment to write to the superintendent medical officer and inclosing a stamped addressed envelope. Despite these methods, the result is not encouraging—of 344 cases referred to medical men only 58 sought advice, a percentage of 16·8. Dr. Rolleston suggests that if local committees could be formed (presumably care committees) better results would be obtained, but the difficulties of treatment in Rutland are considerable; for instance, there is no X ray apparatus in the county, and the parents usually obtain some expensive quack remedy for the treatment of ringworm from the grocer or chemist. "This," says Dr. Rolleston, "is dabbed on the victim's head from time to time when the parent has nothing else to do." The statistics of nutrition have a special interest because of the facts collected with regard to the method of feeding in infancy. In the group "Entrants and Leavers" 2·8 per cent. of boys and 1·8 per cent. of girls are returned as having very poor nutrition; in the group "Specials," 10·4 per cent. boys and 2·1 girls. Of the "Special" cases information as to the infantile feeding was obtained in 74, and of these 51 were entirely breast-fed and 23 artificially reared. Of the 51 cases 13 were puny, and of the 23 artificially fed 9 showed signs of imperfect nutrition. Among the children in the "Entrants and Leavers" classes, information was obtained about 503, of whom 350 were reared entirely on the breast; of these 350, 58 were badly nourished or showed signs of rickets; of the 153 who were artificially fed, 31 showed similar disabilities. Dr. Rolleston says: "Personally, I should have expected a higher difference between breast and bottle feeding, but it must be remembered that breast feeding is extraordinarily mismanaged." In many cases breast feeding is continued for two years, and in a few for three or four years. It is further noted that the percentage of perfectly nourished children decreases with age, as is also, by the way, the case with the percentage of perfectly clean children. In discussing the question of mental deficiency Dr. Rolleston reports, with regard to the after-employment of such children, that the best results are obtained in agriculture, and that

they are in some parts of the country much sought after by farmers on account of their docility and the absence of any desire to change their employment or to ask for higher wages. The review of the hygienic conditions of the schools is not very encouraging; three of the schools are stated to be good, but methods of cleansing, water-supply, and lavatory accommodation are in some cases seriously objectionable.

Royal Leamington Spa.—Dr. Edward Burnet's report deals with ten schools and 3320 children, and shows in a striking way the superior administrative efficiency of the small as compared with the large educational areas. Dr. Burnet is also medical officer of health, and therefore able to maintain the closest personal and official relations with all agencies which affect school life. The small number of the schools makes it possible for every department of every school to be visited at frequent intervals, "usually once a week," and also to see cases needing medical certificates or information and advice of various kinds at the public health office between 9 and 10 in the morning. "Twelve months' experience," says Dr. Burnet, "of this early morning's work has convinced me of its very great value. As a result of this the relations between the children, the parents, and myself are most intimate and cordial." No doubt it is due to the establishment of these relations that the report is able to state that "in every instance where remediable abnormal conditions had been pointed out, successful treatment had been adopted." Dr. Burnet also considers that as a direct result of medical inspection, and the direction of parents' attention to classes of defect noticed in school work, the improvement in remediable conditions "has been extended to many who were not at that time [that of medical inspection] of school-attending age." It is to be hoped that due notice will be taken of the sentences which say that "the school should make up for the deficiencies of the home. In none of the schools have I seen the marked presence of soap and clean towels." Facilities for treatment of vision defects, of dental caries, of otorrhœa, and of skin diseases are seriously lacking, and in view of the optimistic report on treatment quoted above one is forced to conclude that these ailments are, in the absence of such facilities, classed as non-remediable. Dr. Burnet recommends that the education authority should arrange for vision defects to be treated by special arrangement with the only resident ophthalmic surgeon.

County of Kent.—The question of mental deficiency is discussed at some length in Dr. W. J. Howarth's report, and a valuable map supplied of the distribution of these children over the county. It is pointed out that mentally defective children are a serious difficulty in county areas, being so few in number that no convenient centre can be arranged for a special day school, the only alternative being a residential institution. As facilities for such special treatment do not yet exist in Kent, exclusion from ordinary schools is not advised unless the cases are of such a nature as to distinctly interfere with efficient administration. There are in the county 338 cases, and 61 others are under observation with special reference to their mental condition; there are some 80,000 children altogether on the rolls, the mental defectives contributing, therefore, about 4·2 per 1000 of the school population. A table of the schools at which such children attend is also given, from which it appears that as a rule not more than one or two children attend in any one department. But in a few cases there are three children, in two cases six, in two cases seven, and in one case 15. Dr. Howarth suggests that so far as counties are concerned State provision of the necessary accommodation is the way out of the difficulty. There were, further, 76 cases of epilepsy, in not a single case of which was it possible to obtain special treatment. Here, again, is a strong case for State provision, as practically nothing is done for this class of case anywhere. Statistics are given of the total number of defects requiring treatment in 1909 and 1910, and the total number which obtained it, but inasmuch as these include treatment at home and by druggists, and are not checked as to whether the treatment was effective, they have not much weight. Also defects are mentioned, not children, and therefore one is unable to estimate the influence of social circumstances and social groupings so easily as would otherwise be the case.

Lindsey County.—Dr. R. Ashleigh Glegg reports that in the case of 1649 children showing 2079 defects no advice was sought for in over 79 per cent. It must, however, be noted that no special facilities for treatment exist in the area. Reporting on nutrition, 2·6 per cent. boys and 3·14 per cent. girls are returned as "bad nutrition," but out of 6749 children 7 per cent. were markedly anæmic and 14 per cent. anæmic in a lesser degree. These two sets of figures appear contradictory. Dr. Glegg urges the necessity of definite education on the subject of choice of food and cookery. In an appendix codes of instructions and regulations for the guidance of the assistant medical inspector are given, as well as the forms used in connexion with medical inspection and for giving information in regard to infectious diseases.

County of Essex.—Dr. H. W. Sinclair presents an interesting report very fully supplied with useful statistical tables. In certain schools children with ringworm are allowed to attend if (1) the whole of the hair is cut very short; (2) the affected portion of the head is daily covered with ointment; and (3) a clean cotton cap is worn, covering the whole head and securely fastened. At Loughton, Buckhurst Hill, and Woodford experimental dental clinics have been started.

County of Hertfordshire.—A useful analysis is given in table form of the differences in defects found in rural and urban children. Some are very marked. The proportion of eye defects (rural to urban) is, for instance, 84 to 52 for all children, for boys 109 to 61, and for girls 137 to 103. The defects in girls' vision are worse than the boys' at each age both in urban and rural areas. Open-air classes are held throughout the county in summer. Mr. F. E. Fremantle hopes to extend their use.

Dunfermline.—An interesting account, with photographs, is given of the school clinic started in February, 1910. Two rooms have been set apart for this in the institutions of the Carnegie Dunfermline Trust, and the sending of cases to the clinic is in the hands of private practitioners, who send what they consider suitable cases after they have been medically inspected and referred to them, in the first instance, by the inspector. Mr. J. C. Bridge urges the establishment of an open-air recovery school.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns, having an estimated population of 16,157,797 persons in the middle of this year, 7781 births and 5266 deaths were registered during the week ending Sept. 23rd. The annual rate of mortality in these towns, which had steadily decreased from 21·2 to 17·1 in the four preceding weeks, further declined to 17·0 per 1000 in the week under notice. During the first twelve weeks of the current quarter the annual death-rate in these towns averaged 16·7 per 1000, while in London during the same period the mean annual death-rate did not exceed 15·5 per 1000. The recorded annual death-rates in the 77 towns last week ranged from 5·3 in Handsworth (Staffs), 6·1 in Hornsey, 8·3 in King's Norton, and 10·2 in Tottenham, to 24·5 in Gateshead, 25·7 in Liverpool, 26·9 in Burnley, and 30·0 in Stockton-on-Tees. The 5266 deaths from all causes in the 77 towns last week were 24 fewer than the number returned in the previous week, and included 1559 which were referred to the principal epidemic diseases, against numbers decreasing from 2900 to 1701 in the four preceding weeks. Of these 1559 deaths from the principal epidemic diseases, 1377 resulted from infantile diarrhœa, 61 from whooping-cough, 42 from diphtheria, 40 from enteric fever, 26 from measles, and 13 from scarlet fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases last week was equal to 5·0 per 1000, against 6·7 and 5·5 in the two preceding weeks. The deaths of infants under 2 years of age attributed to diarrhœal diseases in the 77 towns, which had steadily decreased from 2714 to 1540 in the four preceding weeks, further declined to 1377 last week, and caused the highest annual death-rates of 9·3 in Northampton, 9·9 in Hull, 10·0 in Stockton-on-Tees, 10·3 in Burnley, 10·4 in Swansea, and 11·4 in Middlesbrough. The deaths referred to whooping-cough, which had been 58, 58, and 55 in the three preceding weeks, rose last week to 61, and included 15 in London, 4 in Sunderland, and 3 each in Birmingham, Bury, Manchester, Leeds, and Hull. The fatal cases of diphtheria, which had been 35, 40, and 27 in the

three preceding weeks, rose to 42 last week; 13 deaths were recorded in London, 5 in Liverpool, 3 in Bristol, and 3 in Stoke-on-Trent. The deaths attributed to enteric fever, which had steadily increased from 11 to 41 in the five preceding weeks, were 40 last week, and of these 12 were registered in London, 3 in Liverpool, and 3 in St. Helens. The deaths referred to measles, which had declined from 59 to 25 in the five preceding weeks, numbered 26 last week, and included 7 in London and its suburban districts, 3 in Liverpool, and 3 in Salford. The 13 fatal cases of scarlet fever were equal to the number returned in the previous week; 4 deaths were registered in London, 2 in Bristol, and 2 in Stoke-on-Trent. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had been 1327, 1349, and 1454 at the end of the three preceding weeks, had further increased to 1532 on Saturday last; 240 new cases of this disease were admitted to these hospitals during the week, against 168, 217, and 264 in the three previous weeks. These hospitals also contained on Saturday last 853 cases of diphtheria, 225 of whooping-cough, 142 of enteric fever, and 86 of measles, but not one of small-pox. The 1356 deaths from all causes in London last week were 33 in excess of the number in the previous week, and included 113 which were referred to diseases of the respiratory system, against 95 and 97 in the two previous weeks. The deaths attributed to different forms of violence in the 77 towns, which had been 171 and 169 in the two preceding weeks, further declined last week to 160, and 326 inquest cases were registered. The causes of 32, or 0·6 per cent., of the deaths registered in the 77 towns during the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death last week were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, Portsmouth, and in 47 other smaller towns. The 32 uncertified causes of death in the 77 towns last week included 4 in Birmingham and 2 each in London, Liverpool, St. Helens, Manchester, Salford, and Preston.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of this year, 835 births and 547 deaths were registered during the week ending Sept. 23rd. The annual rate of mortality in these towns, which had been 17·2, 16·4, and 15·7 in the three preceding weeks, rose to 16·7 per 1000 during the week under notice. During the first 12 weeks of the current quarter the annual death-rate in these Scotch towns averaged 15·2 per 1000, and was 1·5 per 1000 below the mean rate during the same period in the 77 large English towns. The annual death-rates in the Scotch towns last week ranged from 13·0 and 14·6 in Paisley and Greenock to 19·0 in Dundee and 20·3 in Perth. The 547 deaths in the eight towns last week were 31 in excess of the number in the previous week, and included 95 which were referred to the principal epidemic diseases, against 105 in each of the two preceding weeks; of these 95 deaths, 65 resulted from diarrhœa, 12 from whooping-cough, 5 from measles, 5 from scarlet fever, 5 from diphtheria, and 3 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 2·9 per 1000, and was 2·1 below the death-rate from the same diseases in the 77 large English towns. The deaths attributed to diarrhœal diseases, which had been 113, 78, and 80 in the three preceding weeks, declined to 65 last week, and included 59 of infants under two years of age; 36 deaths were recorded in Glasgow, 11 in Dundee, 10 in Edinburgh, and 4 in Aberdeen. The deaths referred to whooping-cough, which had been 10, 12, and 8 in the three preceding weeks, rose to 12 last week, and included 5 in Aberdeen, 3 in Glasgow, and 3 in Dundee. The 5 fatal cases of measles, which were slightly in excess of recent weekly numbers, were all recorded in Glasgow. The deaths from scarlet fever, which had been 2 in each of the two preceding weeks, rose to 5 last week, of which 3 occurred in Glasgow. The deaths attributed to diphtheria, which had been 5, 8, and 10 in the three previous weeks, fell last week to 5, and included 2 in Glasgow. The 3 fatal cases of enteric fever were all registered in Glasgow. The deaths referred to diseases of the respiratory system, which had been 24, 53, and 41 in the three preceding weeks, rose to 57 last week, but were 7 below the number returned in the corresponding week of last year. Of the 547 deaths from all causes in the eight towns last week, 166, or 30 per cent., were recorded in public institutions, and 22 deaths were attributed to different forms of violence. The causes of 21, or 3·8 per cent., of the deaths in the eight towns last week were not specified or not certified; in the 77 English towns the proportion of uncertified causes last week did not exceed 0·6 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 514 births and 444 deaths were registered during the week ending Sept. 23rd. The annual rate of mortality in these towns, which had been 22·1 and 19·4 in the two preceding weeks, rose to 20·4 per 1000 in the week under notice. During the first 12 weeks of the current quarter the annual death-rate in these Irish towns averaged 18·3 per 1000; in the 77 English towns during the same period the mean annual death-rate was equal to 16·7, whilst in the eight Scotch towns it did not exceed 15·2 per 1000. The annual death-rate last week was equal to 22·6 in Dublin (against 15·6 in London), 20·2 in Belfast, 19·7 in Cork, 12·8 in Londonderry, 23·1 in Limerick, and 24·7 in Waterford; whilst in the 16 smallest of these Irish towns the mean annual death-rate did not exceed 14·8 per 1000. The 444 deaths from all causes in the 22 Irish towns were 16 in excess of the number returned in the previous week, and included 122 which were referred to the principal epidemic diseases, against 130 and 134 in the two previous weeks; of these 122 deaths, 111 resulted from diarrhœal diseases, 5 from whooping-cough, 3 from scarlet fever, and 3 from enteric fever, but not one from small-pox, measles, or diphtheria. These 122 deaths from the principal epidemic diseases were equal to an annual death-rate of 5·5 per 1000. The mean rate from the same diseases in the 77 English towns was equal to 5·0, while in the eight Scotch towns it did not exceed 2·9 per 1000. The deaths attributed to diarrhœal diseases, which had been 141, 117, and 121 in the three preceding weeks, declined last week to 111, and included 106 of infants under two years of age; 48 deaths occurred in Belfast, 46 in Dublin, and 5 in Cork. The 5 fatal cases of whooping-cough were equal to the number in the previous week; 3 deaths were registered in Dublin and 2 in Belfast. The 3 deaths from scarlet fever were also equal to the number in the preceding week and were all recorded in Dublin. The 3 fatal cases of enteric fever, all of which occurred in Dublin, were slightly in excess of recent weekly numbers. The deaths referred to diseases of the respiratory system, which had been 31, 44, and 42 in the three preceding weeks, were 43 last week. Of the 444 deaths from all causes in the Irish towns last week, 104, or 23 per cent., were recorded in public institutions, and 6 deaths were attributed to different forms of violence. The causes of 16, or 3·6 per cent., of the deaths registered in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes of death in the week under notice did not exceed 0·6 per cent. in the 77 large English towns, but was equal to 3·8 per cent. in the eight Scotch towns.

THE SERVICES.

1ST LIFE GUARDS.

Surgeon Lieutenant-Colonel Benjamin W. C. Deeble retires on retired pay (dated Sept. 27th, 1911).—Surgeon Captain Robert M. Cowie from the 2nd Life Guards to be Surgeon-Major (dated Sept. 27th, 1911).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel J. Meek, at present holding medical charge of the military hospital at Cosham, has been selected for the higher rate of pay under Article 317 of the Royal Warrant. An exchange of positions on the roster for service abroad has been sanctioned by the War Office between Lieutenant-Colonel J. H. Daly, serving at Limerick, and

Lieutenant-Colonel F. W. G. Gordon-Hall, holding medical charge of the military hospital at Glasgow. Major F. J. Brakenridge has been appointed a Specialist in State Medicine by the Army Council. Major L. P. More, on return from a tour of service in the Northern Army, India, has been detailed for duty in the Southern Command. Major G. T. K. Maurice has been transferred from the military hospital, Bulford, to Tidworth Park, Salisbury Plain. Major T. H. J. C. Goodwin, D.S.O., has arrived home on leave of absence from the military hospital, Quetta. Major C. R. Evans has been detailed for a tour of service in the Maltese Command during the coming trooping season, in succession to Major J. A. Hartigan, who has been ordered to proceed to North China. Major J. F. Burke has been selected for appointment as Medical Officer in Charge at Penally. Captain J. H. Brunskill has been appointed Specialist in Bacteriology by the Army Council. Captain A. J. Hull, on completion of a course of instruction for promotion to the rank of Major, has been appointed for duty in the London District. Captain F. W. W. Dawson has been transferred from Ticknock Camp to Dublin. Captain C. G. Thomson, on return to duty from leave of absence, has been posted to the Military Hospital at Edinburgh. Captain R. L. V. Foster has taken up duty in the Devonport District. Captain F. A. McCammon has arrived home on leave of absence. Captain H. H. J. Fawcett has been selected for appointment as Adjutant of the Home Counties Division School of Instruction, Royal Army Medical Corps. Captain T. W. Browne has been granted an extension of leave. Captain S. M. W. Meadows has been appointed to the Tidworth District, Salisbury Plain. Captain R. H. Bridges has taken up duty at the Royal Victoria Hospital, Netley. Lieutenant C. G. Sherlock has been transferred from Rawal Pindi to the Station Hospital at Lahore. Lieutenant P. S. Tomlinson from the Military Hospital at Tidworth Park, Salisbury Plain, has taken up duty at Wedgenock Park.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel W. Vost has been appointed to officiate as a Civil Surgeon of the first class during the absence on leave of Lieutenant-Colonel J. Morwood. Lieutenant-Colonel B. B. Grayfoot has relinquished charge of the duties of Deputy Sanitary Commissioner, Sind Registration District. Major E. S. Peck has been granted six months' leave of absence home from India. Major G. H. Stewart has taken up duty as Deputy Sanitary Commissioner in Burma in succession to Major N. P. O'Gorman Lalor. Major A. Fenton, on transfer to Rangoon, has been succeeded as Civil Surgeon of the Mandalay District by Major P. Dee on return from leave. Major F. A. L. Hammond has been appointed Civil Surgeon at Bassein in succession to Captain E. A. Walker. Captain E. Owen Thurston, on return from furlough, has been appointed to officiate as Professor of Surgery in the Medical College, Calcutta, during the absence on leave of Major C. Stevens. The services of Captain E. Bisset have been placed temporarily at the disposal of the Government of the United Provinces for plague prevention duties. Captain S. B. Mehta has been granted privilege leave of absence for 30 days. Captain F. P. Mackie has been appointed to officiate as Civil Surgeon of Farrukhabad. Captain S. C. Pal, at present holding medical charge of the depôts at Fatehgarh, has been appointed to officiate as Civil Surgeon to the Fatehgarh District in succession to Captain H. R. Nutt, transferred to Ayamgarh. The services of Captain J. Morison have been replaced at the disposal of the Government of India. Captain F. W. Sumner has been transferred from Bijnor to Shahjahanpur to officiate as Civil Surgeon in succession to Lieutenant-Colonel J. Morwood, who has been granted leave of absence.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant John R. R. Trist is confirmed in his rank.

FRENCH NAVAL DISASTER.

The sympathy of England, in common with that of every other civilised country, was spontaneously offered to the French nation when the terrible disaster which occurred to the battleship *Liberté* became known. The vessel caught fire in Toulon Harbour in the early morning of Sept. 25th, and after a series of explosions broke in two and sank.

Correspondence.

"Audi alteram partem."

THE NATIONAL INSURANCE BILL.

To the Editor of THE LANCET.

SIR,—Before the profession pledges itself to any particular course in regard to the above, I think a great deal more consideration should be given to the various points than there has been up to now, and it appears to me that the interests of medical men at present holding club appointments have not been safeguarded or even considered. These appointments have in some cases been held for generations in the same family, in other cases they have been bought by the payment of substantial sums. The appointments are now it seems to end without compensation, and the work and its emolument are to be thrown open to every practitioner in the district, and even out of it, and every one assured to have the "free choice of a doctor."

The Chancellor offered to relieve the profession acting under the Bill of the expense of drugs and to grant a very much higher scale than that at present in force in contract practice. His offers have been declined, and there has been no stipulation for an enhanced, reasonable, but adequate minimum scale. It is almost past belief that it has been seriously proposed that the whole matter of the payment for medical services shall be left an open question, to be arranged by medical men in each district with the Local Health Committee. The control of Friendly Societies has been bitterly opposed, yet at the same time the control by the Local Health Committee is accepted.

I can only point out that the printed Bill has apparently never been read, for the Health Committees are to be constituted as follows: one-third by members of local sanitary authorities, one-third elected by Friendly Societies, one-third elected by the assured workmen. Health Committees thus constituted would naturally have no sympathy for the interests of medical men, and would be more difficult to deal with even than with the great Friendly Societies. Medical men, knowing the methods of local sanitary authorities in the past, will agree to this. Again, it is inconceivable that medical men in each district are to be left to bargain with committees of laymen, two-thirds of whom are working men wishful to do the best for their society. What would it mean? Different scales in different districts; the present club practices would be split up among many practitioners, each appointment being worth next to nothing, the most capable and better qualified medical men, of course, declining to have anything to do with the working of the Act.

The "free choice of a doctor" is in the opinion of everyone who has had experience certain to lead to an immense amount of malingering, and the doctor who gives certificates freely will get the practice, and the honest, conscientious practitioner will lose it. There will be temptations which should not be put before struggling professional men. The attitude taken up in some quarters is, I think, a mistake, as the suggestion of a strike is an insult to the profession and also impracticable; the non-safeguarding the interests of club doctors who have faithfully carried out work under extreme disabilities is unfair, and there will be humiliation brought to every medical man who is reduced to squalid bargaining with laymen as to his remuneration.

With an intimate knowledge of all ranks of the profession, and looking at the matter from an unbiased and outside point of view, I can only urge that the "free choice of a doctor," the splitting up of the work of the clubs among many, with the question of remuneration not settled by the Bill but left to irresponsible bodies of laymen, to be fixed upon after consultation with keenly competing practitioners, will destroy the profession in the eyes of the public, and in the interests of the State and the well-being of the people would be absolute madness.

It may be asked, Is there an alternative? Is it possible to secure the best medical service to the people without undue expense to the State, and with honour, and sufficient emoluments to medical men? I say "Yes," in one way, and in one way only, by a "State Medical Service," every

man appointed to have the right to the title of State Medical Officer. That in itself would be a valuable asset. The members of the profession holding club appointments, being otherwise properly qualified, should in the first instance be appointed in country districts, and where suitable; but gradually in large towns there should be established clinics, with whole-time medical officers, admitted to the Service by examination, with good expectations of promotion, and in old age a pension.

The control of Friendly Societies has been objected to. I have shown that the control of a Health Committee would be practically the same thing, or worse, yet it is perfectly certain that there must be control, and I venture to say that such control should only be in the hands of a Secretary of State, responsible to Parliament. Friendly Societies and Health Committees will be certain to be interested, and their advice will in many cases be valuable, but I think it will be agreed that they should have no power over medical officers of the State, who should be called upon to do their duty without fear or favour.

It must be remembered that under the Bill the State will be very largely interested, as also every class of employer and employed, and it must be essential to the financial success of the Act that only those assured persons who are really disabled by ill-health are allowed to obtain benefit. On the Friendly Societies and Health Committees will be cast the duty of dispensing the weekly payments, and they will have to depend, in the first instance, on the certificates of the medical officers attending the assured.

I yield to no one in my belief in the honesty of the great mass of the working classes. I have seen in numberless cases the greatest anxiety to get back to work, but I have also been obliged to come in contact with many cases of exaggerated claims or absolute malingering. Seeing that the Act will apply to a much greater number of persons than ever were dealt with under the Workmen's Compensation Act, it is impossible to ignore the fact, that there must be a large amount of malingering under the National Insurance Act, unless provision is made for dealing with it from the very beginning. Medical officers with every desire to do right will have, in any case, a delicate duty to perform in discriminating between just and unjust claims, and they should be subjected to no outside influence which might by any stretch of imagination be supposed to bias their judgment.

Again, the profession is not only interested in medical officers attending the employed. There must be medical men appointed as referees to act when the condition of an insured person is in dispute, and these referees, if they are to retain the confidence of the public, must be absolutely unbiased and above any sort of influence, exerted by either Friendly Societies desirous of reducing claims on their funds, or by assured persons exaggerating their disability or inventing it.

I feel sure that medical officers can only obtain a position, unsubjected to outside influence, by appointment by the State, and controlled only by a State department, the head of which is responsible to Parliament.

I am, Sir, yours faithfully,

South Hampstead, Sept. 25th, 1911. ALBERT BENTHALL.

CONDENSED MILKS IN THE INFANT DIETARY.

To the Editor of THE LANCET.

SIR,—Whilst agreeing with your very timely and wholesome condemnation of the low grade machine-skimmed condensed milks as foods for children, I fear the casual reader will mistake your remarks for an attack on condensed milk in general. Milk, to be a desirable food, must contain all its natural fat, but that is not all; it must also be clean. The commodity sold by the itinerant milkmen is never very clean and often revoltingly dirty, as was shown by the late Mr. Ernest Hart.[1]

Some of the pasteurised milk sold is unfit for food by the time it reaches the consumer. In January of last year a sample of pasteurised milk was seized by the authorities of St. Marylebone and found to contain 22,415,000 germs per cubic centimetre, with other etceteras, including pus. The high-grade condensed milks sold in every grocer's shop throughout the country are clean, and in this lies their value when compared with the fresh milk ordinarily sold. Many more children have been killed by filthy fresh milk than ever contracted rickets from being fed on Swiss or other good brand of full-cream condensed milk. It is one thing to diagnose rickets in a child fed on condensed milk, but quite another to prove that the condensed milk caused the rickets.

The late Dr. H. Ashby wrote[2]—

> I do not doubt that a good condensed milk is better and more wholesome for the infant than much of the so-called fresh milk which is retailed to the poorer classes in our large cities; and it is a useful substitute for fresh milk when, as often happens in the summer, the milk-supply is swarming with micro-organisms.

In a properly managed condensery all the milk employed is obtained from carefully selected and regularly inspected farms; after the addition of the sugar it is condensed in a vacuum pan at a temperature of 120° F. Surely this is far less likely to injure milk than the rough and ready sterilisation to which fresh milk is subjected in the domestic saucepan. My own five children began to take Swiss milk when only a few days old, and none of them have shown any signs of rickets. I have seen hundreds of other people's children similarly fed, and equally healthy. By all means let us order fresh milk whenever we can do so with confidence, but not unless we can truthfully say that fresh milk is clean milk.

I am, Sir, yours faithfully,

London, S.E., Sept. 23rd, 1911. JOHN ROUND.

To the Editor of THE LANCET.

SIR,—At a general meeting of the Condensed Milk Clearing House and Defence Association held this day, at which all the principal manufacturers and importers of skimmed milk (representing 95 per cent. of that trade) were present, the recent report of Dr. Coutts to the Local Government Board was considered, also the article which appeared in your issue of Sept. 16th.

The manufacturers and dealers in skimmed condensed milk have no desire to represent the article as other than it is. They label it "machine skimmed milk" in accordance with the requirements of the legislature, and they do not desire to represent that it is in ordinary cases a suitable food for young infants; but they strongly resent the suggestion that it should be labelled "unfit for infants' food," as they consider that this would convey a false impression that it is unwholesome, and it would unnecessarily injure the sale of a useful and cheap article of food, which is a great boon to the working classes.

The meeting considered the wording proposed by the writer of your leading article and they desired me to express their thanks for the suggestion, not only because it conveys in an unobjectionable form all the Local Government Board report proposes, but it defines very happily the period during which condensed milk should be avoided in infant feeding. The following resolution was unanimously passed and will immediately be carried into effect:—

> Resolved that all labels on tins of machine-skimmed condensed milk in addition to the words "machine skimmed" as required by the legislature shall bear in clear type the words "not a substitute for mothers' milk" in accordance with the suggestion made by THE LANCET.

I am, Sir yours faithfully,

U. A. CLEEVE, Chairman.

69, Mark-lane, London, E.C., Sept. 26th, 1911.

To the Editor of THE LANCET.

SIR,—I have read with considerable interest Dr. F. J. H. Coutts's report to the Local Government Board on condensed milk and your leading article thereon. I take it that this represents the medical view of condensed milk, but I think the commercial side of the question is also worthy of your consideration.

The condensing of machine-skimmed milk is the utilisation of the otherwise waste product of butter-making. Skimmed milk can only be used for the feeding of pigs, preparation of skimmed cheese, making of milk-powder or machine-skimmed milk, and of these the latter is probably

[1] Brit. Med. Jour., vol. i., 1897, p. 1167.
For details of the bacteriological and chemical examination of various brands of condensed milk see "Condensed Milk," by H. Dold and E. Garrett, *Journal of Royal Institute of Public Health*, 1910, vol. xviii., p. 294.

[2] Ashby, Health in the Nursery, p. 101.

the most valuable and the most easily assimilated form. All the manufacturers of condensed skimmed milk are butter manufacturers, and derive the bulk of their profits from the butter part of the undertaking.

Dr. Coutts states that he finds there is a considerable consumption of machine-skimmed milk for infant feeding, but he gives no figures whatever to prove his contention; in fact, the only figures given show that the total amount of infants fed on condensed milk is only 3·1 per cent. in Brighton (all kinds), 8 4 per cent. in Derby (all kinds), and in Salford 0·4 per cent. (skimmed only).

The manufacturers of machine-skimmed milk are convinced that only a very small part—probably only 1 per cent.—of their condensed milk is used as a sole food for infants, and every indirect test (since a direct test is impossible) tends to confirm this view. The other 99 per cent. are used for ordinary household purposes where the absence of fat is either unimportant or even desirable. It is nearly always used undiluted, and in a form which Dr. Coutts admits to be an unfavourable medium for the development of many bacteria. If it were correct, as stated by the Select Committee on Food Adulteration, that machine-skimmed milk was largely used for infant feeding, the effect of the notification on the label that the milk was machine skimmed should have lessened the consumption, but, on the contrary, it increased. It increased still more when a few years ago all the manufacturers who are members of the Condensed Milk Clearing House Association voluntarily decided they would henceforth put on their labels an indication that machine-skimmed milk was not suitable as sole food for infants, and such increase would not have taken place had any large proportion been used for this purpose.

The manufacturers of this article would probably have no objection whatever to stating on their labels that the milk is "not a substitute for mothers' milk," as suggested by you, since they have never sold it for that purpose; but the words which are often suggested, viz., "unfit for infants," are objected to, as it is felt that nine-tenths of the persons who use this milk would assume that what was unfit for infants was also unfit for children and adults, and they would not be able to understand that the unfitness lies merely in the absence of fat, and that the age of the infant is a governing factor. This same article which is nutritively insufficient for a child of 3 months becomes, for a child of 3 years, an excellent food if spread on bread and butter, and, in the case of the poorer classes where cheapness is a leading consideration, it is in this way almost an ideal food. It is certainly better than jam or golden syrup, and cheaper than meat; it contains more proteids than bacon and nearly as much as fat mutton or other meats. The superiority of machine-skimmed condensed milk, used as suggested, over potted "delicacies" is so evident that it is remarkable that medical men have not more often advised it as an item in the dietary of poorer households.

I think it is scarcely fair to conclude your article with the words "the State should step in ..... to render more difficult the commercial game of making things appear what they are not," thus suggesting that the manufacturers of machine-skimmed milk are endeavouring to foster its sale by misleading the public. I believe I am right in saying that they are the only manufacturers who describe as fully the article sold by them, and who point out the uses to which it should *not* be put. Your righteous condemnation of certain commercial methods would apply better to many of the patent foods which are advertised "for infants and invalids," and which are even less suitable than machine-skimmed condensed milk for the feeding of infants, at any rate so far as proportion of fat is concerned. I would refer you to Dr. R. Hutchison's book on "Food and the Principles of Dietetics," and many of your readers who condemn machine-skimmed milk would be surprised to find that patent foods they have recommended are even more incomplete.

I venture to say that no action should be taken with regard to the very limited sale of machine-skimmed condensed milk for infant feeding unless the same tests be applied to all patent or infant foods—whether sold under a fancy or proprietor's name or otherwise—and if a percentage of only ½ per cent. or 1 per cent. of butter fat be a reason for labelling 100 tins of this milk "unfit for infant food" (of which only one is likely to be used for that purpose) that any other so-called "infants' food" which contains too low a percentage of fat shall be labelled in the same way.

I am, Sir, yours faithfully,

CHAS. LEHMANN,
Director, R. Lehmann and Co., Limited.

Monument-street, E.C., Sept. 20th, 1911.

*** We publish this letter with pleasure. The policy of the members of the Condensed Milk Clearing House Association is obviously an upright one, and no praise is needed from us for the honest label which they agreed to adopt. The manufacturers do not object to the use of machine-skimmed milk being discouraged as a substitute for mothers' milk and put words to that effect upon the label. We have already agreed that machine-skimmed condensed milk, apart from its fat, is a valuable food, and our correspondent rightly draws attention to its useful applications in this direction. We agree, also, that there are several preparations upon the market masquerading as foods suitable for the suckling, which are totally unfit for the purpose, not only because they show a deficiency of fat, but because in several of them raw starch is present. On the other hand, some at least of these foods are clearly intended to be used as adjuvants to the milk diet, the directions on the label clearly stating that milk is to be added to the food before it is ready for the infants' use. Such a direction would, of course, appear superfluous in the case of a machine-skimmed product called milk. As a rule, however, the price asked for such foods is a good deal more than that commonly demanded for a tin of machine-skimmed milk. The great cheapness of skimmed condensed milk, which after all, as our correspondent points out, is a by-product in butter-making, is a strong reason for protecting the very poor from ignorantly using it to fulfil cheaply an object which it never can fulfil. The whole question of the sale of infant foods for rich and poor alike calls for a controlling measure to protect the public from acting upon statements which misrepresent physiological facts.—ED. L.

DESICCATED ANTIVARIOLOUS VACCINE.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Sept. 24th, 1910, there is an annotation, "The Influence of Age and Temperature on the Potency of Diphtheria Antitoxin." This may not have interested the most of your readers, who are within easy reach of manufactories of sera, but for a few thousands who are not so situated it is extremely interesting. In a previous number (May 21st) you had already published "A Note on Desiccated Culture Media," which was, I am sure, welcomed by many of us outsiders. With the same object in view—i.e., to be of service to practitioners abroad—I would call attention to an article published in the *Bulletin de la Société de Pathologie Exotique*, séance du 21 Juillet 1909, tome 2de, No. 7, par Pierre Achalme et Marie Phisalix, entitled "Contribution to the Study of the Preservation of Vaccine in Tropical Countries." The production (manufacture) of this desiccated vaccine appears to be simple, and its activity is guaranteed for one year at least, a future communication being promised as to longer duration. I am surprised that some institute has not taken up its manufacture. It would be a boon to many doctors and others.

In THE LANCET of Nov. 26th, 1910, in an article on "Sanitation in India," attention is called to the difficulty in preserving lymph, even with the use of thermos flasks. In the *Medical Record*, N.Y., May 14th, Dr. Heiser, director of health, at a meeting of the Far Eastern Association of Tropical Medicine, says that glycerinised lymph loses its efficacy in ten days. Previously, in the same periodical, another practitioner made a similar observation. Even in Peru, where there has been a vaccine institute for more than 12 years, there is an extensive field for the use of desiccated vaccine. Some portions of the Republic are more than a month's journey from the capital; many others have no doctor, and even if

tubes of glycerinised lymph are sent the tubes are not used at once, or they may be opened and kept open, and so used for days. In fact, if I were asked, Has small-pox diminished since the establishment of the vaccine institute? I should hesitate in giving an answer. Reliable statistics for years before or after the foundation of the institute are not obtainable. This is perhaps not much to be regretted, as there is a tendency to look askance at statistics, as if one were trying to prove what is untrue.

Here we have not yet arrived at that ultra stage of civilisation which produces antivaccinationists. What we have to contend with are carelessness, curious ideas, and inefficient vaccination. As to curious ideas—immunity to small-pox is conferred by being born in a year of a solar eclipse or a leap year, or being a seventh child, or other equally mysterious "secret of nature"—quite unknown to doctors, but an open book to *sages femmes*. There is another obstacle in the way of vaccination. A rumour gets about that the vaccine is "infested." The people then refuse to have their children vaccinated. I tried to find out what was meant by "infested," but could get no proper explanation. The word had been heard and the people were terrorised. At first I thought it meant that the vaccine was contaminated with syphilis. Against this was the fact that I had never seen a case of vaccine syphilis, and that, 40 or 50 years ago, syphilis might be said to be non-existent here. Within the last 30 years or so this is being remedied (?)—civilisation and its apparently almost necessary accompaniment, syphilisation, have made considerable advances. After puzzling over the "infested" vaccine for some time I came to the conclusion that it meant that the vaccine would cause small-pox. I came to this conclusion as I observed that this rumour got about particularly when there was already an epidemic of variola and one was advising the people to get their children vaccinated. As the children had been visiting or playing with other children convalescent from the disease, it was not strange that they got the disease; if they had been vaccinated two or three days previously, naturally the vaccination was blamed as being "infested."

With reference to inefficient vaccination:—Is it to be expected, especially amongst the poor, that they will take the time or trouble to have their children vaccinated three or four times, seeing that it has not taken? No, they will naturally ascribe the accident to one or other of the above-mentioned "secrets of nature." Many of these evils would disappear if one had a thoroughly reliable vaccine such as this "desiccated" seems to be. As it would be easily carried and would not require constant renewal it might be constantly taken in ocean-going passenger steamers, so, perhaps, saving some lives and shortening quarantines. Explorers might also find it useful for vaccinating their baggage carriers before entering suspected country.

I am, Sir, yours faithfully,

Arequipa, Peru. J. DICKSON HUNTER, M.D. Edin.

INDIGESTION AND CATARRH OF THE THROAT AND NOSE.

To the Editor of THE LANCET.

SIR,—Some years ago I had occasion to point out in your columns that not all coughs and colds were related to disorders of the lungs; indeed, I showed conclusively that cough as a symptom was more often not associated with lung trouble. I pointed out that taking the respiratory tract as a whole and dividing this into the upper respiratory tract and the lower respiratory tract, or all that portion above and below the cricoid cartilage, a very large percentage of cases of coughs were due to affections of the upper respiratory tract, a very few in reality due to affection of the trachea and lung proper. It followed from this that every physician who is called upon to diagnose and treat coughs should be an expert rhinologist and laryngologist.

The amount of medicine that is annually swallowed by patients attending the out-patient departments of our hospitals, who apply for the relief of coughs, is appalling and regrettable. Most of these cases are due to affections of the upper respiratory tract requiring some local application of an astringent or soothing nature. It is unreasonable to conceive that nature would expose a vital organ such as the lung to all the petty troubles and grievances due to the ever-changing conditions of the atmospheric environments. The same argument applies with equal force to the stomach. Indigestion is one of the commonest of troubles, yet in but few cases is the stomach itself at fault.

The alimentary tract extends from the lips downwards, yet the possible causes of indigestion existing in the mouth, nose, and pharynx are mostly ignored. As one who is interested in diseases of the upper respiratory and alimentary tracts one is struck with the quite common associations of catarrh of the upper respiratory tract and indigestion. The relation of these two functions is close and intimate. The respiratory tract crosses the alimentary tract at a point in the pharynx, and both the lungs and stomach are open and liable to be infected and disturbed by abnormal conditions of either the mouth or nose. Septic conditions of the mouth, teeth, tonsils, and other glands, and catarrhal conditions of the nose and post-nasal space are quite common affections in these temperate latitudes.

In post-nasal catarrh and catarrh of the pharynx large quantities of unhealthy germ-laden mucus find their way into the stomach and are a common associate of indigestion of the fermentative or flatulent type. A careful examination of the upper respiratory tract and upper alimentary tract in all cases of coughs and indigestion is thus imperatively necessary if a proper diagnosis is to be arrived at.

I am, Sir, yours faithfully,

Harley-street, W., Sept. 25th, 1911. MAYO COLLIER.

A QUESTION IN EUGENICS.

To the Editor of THE LANCET.

SIR,—I have read the correspondence under the above heading, and should like to make a few observations on certain points which it raises.

In the first place it is not easy in these days to sympathise with the writer who thinks that morality is threatened by the campaign against the propagation of degenerates. One understands that society is bound to take care of its "undesirables," but surely there is something morbid in the idea that in this matter "cure" is better than prevention, or that the abolition of some few of the more conspicuous hereditary ailments will leave the philanthropist without a sufficient field for the exercise of his benevolent instincts. Like the parallel argument that to destroy poverty would be to abolish the Christian religion because paupers are required to incite to charity in this world, and to populate the Kingdom of Heaven in the next, the theory may be suspected to be one of those familiar devices under which those who have a vested interest in error are wont to disguise their resistance to salutary change. In saying so I do not, of course, question the sincerity of the writer, who is inclined to look upon eugenists as subverters of morals. Many bad theories have been recommended with the most praiseworthy motives. Many good men have "done harm with the best intentions."

Still more amazing is the opinion favoured by another of your correspondents, which upholds the unrestricted multiplication of the feeble-minded on the ground that the individual, not the race, is the proper subject of moral solicitude. We have hitherto been under the impression that highest reverence is due to the unseen benefactors whose disinterested labours have prepared a happier future for mankind. But this, it seems, is a mistake. Duty is owed only to contemporaries, whose comfort is to be promoted however much it may conflict with the well-being of future generations. The latter may perhaps be entitled to some measure of consideration when to give it would not entail the smallest sacrifice on the part of actually existing people. Thus viewed "in the dry light of intelligence," and apart from sentiment, the doctrine appears so preposterous that it would have been unnecessary to refer to it were it not that the attitude of a good many sociologists towards this question of degeneracy seems to lend it a measure of countenance. Like the fear for morality it is, however, rather a pretext than a creed, and will not, it may be hoped, seriously affect the judgment of the future upon the philanthropy of our age.

A third theory, referred to in your columns—the notion, viz., that in suppressing degeneracy we may be eliminating genius—though in the past supported by high authority, is now admitted to be based very largely upon error. The idea,

e.g., of a connexion between genius and epilepsy, never very widely favoured by physicians, may now be regarded as definitely disproved. Nor are the weak and diseased tendencies, of which genius has been actually convicted, of a kind which any sensible person would regard as prohibitive of marriage. In a quite different category, however, from these is the case in which an individual who possesses genius may have constitutional proclivities which make it likely that his children, if he had any, would be insane or tuberculous or epileptic. Under such circumstances the possibility that genius might be transmitted would be no excuse for the physician who should recommend marriage; nor, *a fortiori*, could the fact that genius has had a tendency to occur in a family which has produced many lunatics be considered to palliate the marriage of a member of such a family who was himself neither a genius nor quite sound mentally. It is significant in this connexion that none of the distinguished men who have advocated the degeneration theory have even hinted that it is wrong to discourage "philoprogenitiveness" in degenerates. It has remained for your correspondent to make the suggestion.

Not only are some of us living in an antediluvian world, in which contemporary tendencies play no part, but we often seem blind to facts of every-day experience. The facts which I have more especially in view are to be met with at any school-attendance committee meeting in our large cities. There, for their part not a little astonished at the special attention they receive, families present themselves, organised on a basis like this. A father who is a drunkard or epileptic, incapable of steady employment, occasionally picking up a few shillings in the lowest lines of casual labour; a wife supporting the family by her earnings; six or seven weak-minded children, who in the necessary absence or frequent confinements of the mother stay at home to do the work of the house. Is this, one is tempted to ask, a fair illustration of the working out of that latest discovery in the higher ethics, the precept, i.e., that we ought to care for the individual and leave the race and the future to look after themselves?

As regards the outlook, were we to judge by the views of some of your correspondents there would indeed be grounds for serious misgiving. For my part I have much confidence in the growth of a saner opinion, of which there are everywhere so many indications, and cannot doubt that, under the pressure of these new ideas, we shall have in the near future a large and wholly beneficent extension of sterilisation as a remedy for the terrible evils from which we at present suffer.

I am, Sir, yours faithfully,

Stoke Newington, Sept. 23rd, 1911. I. B. MUIRHEAD.

THE NOMENCLATURE OF SPINAL DEFORMITIES.

To the Editor of THE LANCET.

SIR,—In your issue of Sept. 2nd appears an article on Spinal Curvatures and their Treatment, &c. Will you allow me space to call attention to the confusing terminology adopted by the author of that article, and to urge upon him and others interested in these deformities the use of a more accurate nomenclature? He writes of several conditions which I will enumerate in turn. 1. In the title of his paper he uses the phrase "spinal curvatures" to include all deformities of the spine—e.g., Pott's angular kyphosis, scoliosis, kyphosis, lordosis, spondylitis, &c. 2. On p. 667, line 23, he uses "spinal curvature" to mean scoliosis. 3. On p. 668, line 9, he writes of "lateral deviation," and in the next line of a "more or less fixed scoliosis" (4) 5. On p. 668, line 47, he writes of "scoliosis." 6. On p. 669, line 23, of "simple lateral deviation." 7. On p. 669, line 24, of "'a curve in the second degree of severity'—that is, a 'true scoliosis,' but not yet fixed" (8). 9. On p. 669, line 40, he uses "fixed curvature" to mean the angular kyphosis of Pott's disease. And finally, (10) on p. 671, line 10, he writes of "lateral curvatures"

Now, Sir, these terms are so used throughout his article that it is very difficult to follow the author's line of thought. Yet by using the simple method I now suggest all confusion would disappear. 1. Omit the phrase "spinal curvatures" of his title altogether and substitute for it "spinal deformities" 2. Write of the deformity produced by Pott's disease as "spinal caries deformity" or "Pott's angular kyphosis." 3. Write of the lateral curvature of the spine in which there is as yet no bony deformity as "postural scoliosis," or "postural lateral curvature." 4. Write of the lateral curvature of the spine in which bony deformity is present as "osseous scoliosis," or "osseous lateral curvature."

Let future authors drop all such terms as "lateral deviation," "more or less fixed scoliosis," "true scoliosis," "fixed curvature," and "a curve in the second degree of severity"; then we shall know exactly what the authors mean.

I am, Sir, yours faithfully,

Harley-street, W., Sept. 25th, 1911. PAUL B. ROTH.

CHRONIC OBSTRUCTION OF THE BOWEL IN A HYDROCEPHALIC IMBECILE.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Sept. 16th, p. 820, a very interesting case is described under the above heading by Dr. A. L. E. F. Coleman and Dr. H. D. Everington. I should like to point out that this case is a typical example of so-called "congenital dilatation of the colon," better called "congenital hypertrophy and dilatation of the colon" (known in Germany as Hirschsprung's disease). The dilatation and thickening of the bowel were not due, as the authors supposed, to chronic constipation, but were the cause of it. I collected a number of these cases for the Jacksonian Essay of 1908, and they will be found in my book on "Diseases of the Colon."

I am, Sir, yours faithfully,

P. LOCKHART MUMMERY.

Cavendish-place, W., Sept. 20th, 1911.

BRITISH HEALTH RESORTS FOR FOREIGN INVALIDS.

To the Editor of THE LANCET.

SIR,—For the furtherance of a movement which may prove advantageous to two great and friendly countries may I ask you to be so very kind as to inform your readers that, taking cognisance of Dr. Neville Wood's paper "British Health Resorts for Foreign Invalids," read before the Royal Society of Medicine and published in THE LANCET of Jan. 7th, p. 12, the French Government has commissioned me to visit the principal health resorts of Great Britain and to issue a report on their suitability for various categories of French invalids, and at the same time to inquire into the practice and teaching of hydrology in the medical schools attached to universities.

I hope at an early date to arrive in London, where my postal address will be the Royal Society of Medicine, 15, Cavendish-square. Thanking you in anticipation,

I am, Sir, yours faithfully,

GUSTAVE MONOD, M.D. Paris, L.R.C.P. Lond., M.R.C.S. Eng.,

Sept. 23rd, 1911. Médecin Consultant à Vichy.

ANÆSTHETICS IN INTESTINAL OBSTRUCTION.

To the Editor of THE LANCET.

SIR,—Following the publication of my clinical notes (of a death under an anæsthetic) in your issue of May 20th last there were several interesting and valuable comments and suggestions in your correspondence columns. All the methods advised for the prevention of such "drowning fatalities" are quite adequate, but some of them have the defect of being complicated to a degree which must lessen the patient's chance of recovery. I refer more particularly to the operation of preliminary tracheotomy with packing the larynx.

In a recent case of complete obstruction, a very old woman, who had fæcal vomiting, a preliminary injection of morphine ¼ gr. and atropine $\frac{1}{150}$ gr. was given. This produced deep somnolence. After administering a very few drops of chloroform on a flannel mask the operation was begun, and at the same time the mouth was opened and sponged out; some dark matter being present, the œsophageal tube was passed and the stomach

washed out. The tube was retained until the end of the operation, when the stomach was again washed out, and the patient, who showed no evidence of shock, was returned to bed. This simple method of preliminary injection, by causing temporary paralysis of peristalsis, made any massive regurgitation impossible, while so little chloroform was required that the presence of the œsophageal tube was no obstacle to the anæsthetist. The essential detail in this method is to grade the dose of morphine according to the patient's age and general condition. One-sixth of a grain will generally be insufficient, except where the patient is emaciated and exhausted; one-third will be too much, unless the patient is big, robust, and alcoholic. If the first dose of morphine prove insufficient to produce somnolence and intestinal paralysis, any second injection must contain atropine, hyoscine, or scopolamine only.

I am, Sir, yours faithfully,

DONALD J. MUNRO.

Great Portland-street, W., Sept. 25th, 1911.

TOXIC EFFECT OF ASPIRIN.

To the Editor of THE LANCET.

SIR,—In answer to Mr. H. Ewan Waller's letter in your issue of Sept. 23rd, I cannot say that either person whose symptoms of aspirin poisoning I mentioned showed signs of minor thyroid inadequacy, but it is perhaps noteworthy that the male patient usually has a brachial blood pressure of only 65 mm. Hg. I am, Sir, yours faithfully,

ALEXANDER BROWN, M.B. Lond.

Bartholomew-road, N.W., Sept. 23rd, 1911.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Recommendations by the Bristol Health Committee.

A REPORT from the Bristol health committee to the city council contains certain very important recommendations. A decision in favour of compulsory general notification of phthisis is urged, as well as the adoption of the Notification of Births Act, 1907, and the transference of the administration of the Midwives Act, 1902, from the watch committee to the health committee. The committee further recommends the appointment of a qualified lady practitioner at a salary not exceeding £100 per annum, to act under the medical officer of health as supervisor of the midwives, the lady health visitors, and such helpers as may be provided by voluntary organisation with the approval of the committee; and it also asks to be authorised to appoint two lady health visitors at salaries not exceeding £80 per annum each, to visit the homes of the poorer classes and give advice as to the care and management of infants and of the homes generally, and to report to the lady practitioner such cases as may require medical advice and assistance. These recommendations prove that the committee and the medical officer of health are impressed with the value of the work done by the school for mothers (to which allusion has been made more than once in these columns), work which they are seeking to promote on a municipal basis by means of the steps recommended.

Bristol Eye Hospital.

Mr. Edmund King, chairman of committee to the Bristol Eye Hospital, has issued an appeal to the public in which he states that, Sept. 30th being the end of the hospital's financial year, the committee finds with regret that it is likely to end the year with a deficit of £700 on the current account, unless this sum is speedily made up by donations. This is partly due to the fact that there have been no large donations towards expenses during the past year.

Hydrophobia from a Fox-bite.

Mr. Richard Bower, master of the South and West Wilts Hunt, died at Sutton Veny, near Warminster, on Sept. 22nd, from a disease stated to be hydrophobia. He was ill only five days. His fatal illness is attributed to the fact that some months ago he was bitten by a fox.

The Gloucestershire Memorial to the late King.

The total amount subscribed to the Gloucestershire Memorial Fund to the late King is £2932. After deducting necessary expenses, the balance will be invested and the income applied towards the promotion of nursing in the county, including the city of Gloucester.

Proposed Memorial Hospital to the late Sir Charles Dilke.

At a large meeting held in Cinderford, Gloucestershire, it was decided to erect a general hospital in the Forest of Dean as a memorial for the political and other services rendered by the late Sir Charles Dilke during his 20 years' political connexion with the district. A committee composed of members of both political parties has been appointed to further the object, and Mr. H. Webb, M.P., stated that there were people in all parts of the world who would welcome the opportunity to aid such a scheme.

The Devon County Asylum.

At a meeting of the Devon county council, held on Sept. 21st, it was stated that Miss Enid Walters, M.B., B Sc. Lond., had been appointed fourth assistant medical officer and pathologist to the Devon County Asylum at a salary of £130 per annum, rising to £140. Lord Clifford said that the asylum committee had never had a lady medical officer appointed before, and the committee was divided about the appointment. Another speaker remarked "that they could not get a male medical officer because of the remuneration offered."

The Devon County Council and the Treatment of Tuberculosis.

At the last meeting of the Devon County Council it was decided to draw the attention of all sanitary authorities in the county to the extensive powers conferred upon them by the Public Health Acts, including the provision of dispensaries for the benefit of persons suffering from tuberculosis. It was also decided to expend £25 on the distribution of suitable pamphlets on the subject at the discretion of the county medical officer of health.

The Exeter Sanatorium.

The Exeter sanitary committee has recommended that permission should be obtained from the Local Government Board to borrow £15,500 for the purpose of enlarging the city sanatorium. It is proposed to enlarge the existing administrative block of buildings and to erect an observation and discharge block; scarlet fever block, with wards to accommodate 22 patients; nurses' rooms and bathrooms; block with wards for diphtheritic cases, to contain 14 beds; a block for enteric fever cases, with eight beds; a laundry, mortuary, stables, ambulance shed, and other necessary offices.

Infantile Cholera at Plymouth.

At the last meeting of the Plymouth borough council Mr. W. Paul Swain stated that 29 infants, aged from 2 to 3 months, who were suffering from "choleraic diarrhœa," had been treated at the corporation hospital from Sept. 2nd to 11th with sea-water injections. Of this number two had died, one from pneumonia (contracted before admission) and the other from diarrhœa. Mr. Swain considered the results eminently satisfactory, as all the children admitted were in a very serious condition. He added that the removal of the infants from unwholesome surroundings and the hospital treatment might have been important factors in their recovery.

A Health Visitor for Devonport.

Acting upon the recommendation of its medical officer of health (Mr. O. Hall), the Devonport borough council has appointed a health visitor and school nurse, with the object of reducing the infantile mortality in the town.

A Board of Guardians' Subscription to an Infirmary.

The Local Government Board has sanctioned the proposal of the Barnstaple (Devon) board of guardians to subscribe £78 to the funds of the North Devon Infirmary.

Proposed Public Abattoirs for Weston-super-Mare.

A Local Government Board inquiry was recently held at Weston-super-Mare (Somerset) into the application of the urban council for permission to borrow £3405 for the purchase of land for the purposes of public abattoirs.

A Workhouse Medical Officer and Anæsthetics.

At the last meeting of the Bridgwater (Somerset) board of guardians it was decided to allow Mr. Penrose Williams, the medical officer to the Workhouse Infirmary, the sum of

10 guineas for one year for the purpose of covering the expense of an anæsthetist in necessary cases.

Tuberculosis Shelters for Tiverton Isolation Hospital.

The Tiverton town council and the Tiverton rural council, the authorities controlling the Tiverton Isolation Hospital, have decided to place shelters for the treatment of consumptive patients in the grounds of the institution. The Tiverton Association for the Prevention and Cure of Consumption will provide the shelters. The patients will be charged for their treatment if they are in a position to pay, otherwise the expenses will be defrayed out of the rates. The Local Government Board has approved of the scheme provided proper precautions are taken.

Death of Surgeon-General C. K. Colston, I.M.S.

Surgeon-General C. K. Colston, of the Indian Medical Service (retired), died at his residence in Teignmouth (Devon) on Sept. 21st, aged 78 years. After his retirement he took up his residence at Teignmouth, where he soon became very popular. He took a great interest in all local matters connected with the town, and more especially in matters connected with education. He was for some years a member of the old Teignmouth School Board.

Death of Surgeon-Major John Raby, I.M.S.

Surgeon-Major John Raby, I.M.S. (retired), who accidentally poisoned himself with an overdose of a narcotic at Paignton recently, qualified as L.R.C.P. & S. Edin. and M.R.C.S. Eng. in 1865, and had been retired from the Indian army for many years. He saw active work in the Abyssinian expedition, and for his services received official recognition from the Government of India. Before going to Paignton he had resided for a long time at Taunton, where he was very popular. He was a great sportsman and very well known in the hunting field and took many prizes at horse shows. He was a successful competitor at various steeplechases in the West of England. Surgeon-Major Raby was highly esteemed at Paignton and much sympathy is felt there for his widow and family.

Sept. 25th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Death of Dr. James Andrew.

THE death of Dr. James Andrew, which took place on Sept. 19th at Edinburgh, has removed from the medical profession in Edinburgh one of its senior members and from the public a much-esteemed physician. Dr. Andrew, who was the son of the late Dr. James Andrew, a well-known physician of his day, received his medical education at the University of Edinburgh and afterwards studied in Vienna and Berlin. He graduated in the University of Edinburgh in 1866, when he took the M.B. and C.M. degrees, receiving the M.D. degree two years later. In 1869 he became a Member, and in the following year a Fellow, of the Royal College of Physicians of Edinburgh. He was President of the College from 1898 to 1900. For five years he was one of the managers of the Edinburgh Royal Infirmary, and was a member of the Scottish branch of the Queen Victoria Jubilee Institute for Nurses. Among the many medical appointments which he held were those of physician and physician-accoucheur to the Royal Dispensary, Edinburgh, examiner in medical jurisprudence to the Royal College of Physicians of Edinburgh, physician to the Royal Asylum for the Blind, physician to the Royal Hospital for Sick Children, Edinburgh, and lecturer on diseases of children at the University of Edinburgh. He was a Fellow of the Obstetrical Society of Edinburgh, a member of the Harveian Society and also of the Royal Medical Society of Edinburgh. For some years Dr. Andrew had been in failing health, and two years ago he retired from active practice. He had always taken the keenest interest in everything pertaining to his profession, and his death will be felt as a personal loss by a very large circle of friends, both medical and lay.

Sanitary Association of Scotland.

The annual congress of the Sanitary Association of Scotland was held at Oban last week, where a very pleasant and also profitable few days were spent. Dr. John Glaister, professor of public health at the University of Glasgow, read a paper on the Latest Aspects of the Problem of Tuberculosis. He said that it had now come to be recognised that the potent factors in the development of tubercular disease were not so much the condition of the soil or altitude of a place as the intimate home life of a people and the conditions of their employment, environment, and consanguinity. The country generally was beginning to recognise the importance of the adoption of reasonably uniform administrative measures for the repression of the disease. The sanatorium was of great service, but it was not suited for all kinds or degrees of cases, and he thought that too high hopes had been built on the sanatorium as a curative institution for phthisis. There was certainly a crying need for the isolation of phthisical patients in the expectorative stage, and also in the hopeless stage, but although sputum was one source of infection, he thought too little emphasis was laid upon the transmissibility of the disease by milk and fresh meat. In his opinion there should be systematic periodic inspection of milk cows by the tuberculin test, compulsory notification to a central authority of all affected animals, destruction of all animals so diseased as to be able to transmit the disease to other animals, and complete isolation of animals slightly affected, and the slaughter of these as the disease tended to develop. Local authorities, rural and urban, should jointly or severally appoint full-time veterinary officers to carry out these duties. Also the Government should by statute empower the Local Government Boards of the United Kingdom to issue regulations and to see that they were carried out, for a uniform system of meat inspection, so that the present conflicting practices should cease. He added that it was futile to expect much further reduction in the total number of cases of phthisis unless notification and provision of hospital and sanatorium treatment became general. Another paper was read on "The Milne Treatment of Scarlet Fever," and after discussion the following conclusions were arrived at: That the value of hospital isolation in the case of scarlet fever had been greatly over-estimated; that more discrimination should be exercised in the selection of cases for removal to hospital; that the Milne treatment of cases in hospital was not justified by the results (but it must be remembered that Dr. Milne's treatment was proposed for cases dealt with *in situ*, not for cases treated in a fever hospital); that the Milne treatment, with any modifications which might suggest themselves, should have a fair trial over the country in cases retained at home which would otherwise be removed to hospital, the particulars being precisely noted. But it was pointed out that it was generally only in towns, where a nurse or nurses could carry out or superintend the treatment of the patients, that the home treatment could be efficiently carried out. "The Difficulties of Sanitary Administration in the Highland Counties" formed the subject of another paper, which was highly interesting in relation to the recent melancholy exposure of sanitary conditions prevailing in Lewis. The difficulties were partly due to geographical conditions, and partly also to the impossibility of removing wholesale the houses which existed in so many Highland villages, which had been handed down from past generations who possessed very crude notions as to sanitation and general hygiene. The great need there was money, and the Government would have to realise that there were cases where the district or parish had not the funds to fulfil the requirements of the Public Health Acts. In these cases it was not only logical, but necessary, that the responsibility should fall back on higher powers—on the counties, and failing them on Parliament. If they got the powers of the Board of Agriculture enlarged and defined so that they could deal with these matters steps might be taken to remove the difficulties which at present existed, and to improve to some definite extent the sanitary condition of the Highlands. It was suggested that a small deputation should wait on the Secretary for Scotland, and after some discussion the suggestion was remitted to the executive committee.

Glasgow Tuberculosis Exhibition.

The Scottish Exhibition at Glasgow, like various other large modern exhibitions, has a section devoted to tuberculosis. This exhibit was opened on Friday, Sept. 22nd, by the Duchess of Hamilton, under the presidency of the Lord Provost of Glasgow, Sir A. McInnes Shaw. An address was given by Sir James Crichton-Browne.

Sept. 25th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Report of the Local Government Board for Ireland.

The annual report of the Local Government Board contains much interesting information concerning the work of the Poor-law Service in Ireland. The removal of the pauper disqualification in connexion with old age pensions had a marked effect on the statistics of poor relief. In one week at the beginning of the year the workhouse population diminished by 3512, and the number in receipt of outdoor relief by 15,391. It would seem, however, that many of those who left workhouses early in the year shortly returned, for at the end of March the number of aged infirm in workhouses was only 2187 less than in the previous year. The average pauperism for the year was 20·9 per 1000 as compared with 22·4 in the previous year. The number of children boarded out or in certified schools was 2623, being 58 less than in the previous year, while there were 5213 healthy children in workhouses. Both the Vice-Regal Commission and the Royal Commission have declared that maintenance in workhouses should no longer be recognised as a legitimate method of dealing with children. The number of mentally afflicted in workhouses has diminished by 90, but there are still 2230 other than those sick in hospital, confined in workhouses. The deaths in workhouses were 10,406 in number, of which 1548 were due to phthisis. The deaths of 15 centenarians were recorded 781 infants under one year old died and 408 from 1 to 5 years of age.

The total amount spent on poor relief in the year was £1,361,062. Of this amount a sum of £118,793 was spent in salaries to permanent and temporary dispensary medical officers. The total number of patients attended was 642,759, of whom 479,644 were seen at dispensaries, and 163,115 at their own homes. The number of vaccinations and revaccinations performed was 81,412. The Board notes continued niggardliness in the matter of the granting of pensions to medical officers. In one instance, in the year under review, a medical officer with an excellent record of over 40 years' service and eligible for a pension of £207 8*s* 2*d*. was awarded £80 a year by the guardians. As is pointed out, "pensions are a reward for past good services, and should be regarded as deferred pay and not as compassionate allowances."

Having recalled the case of a medical officer who was deprived of office on account of having been reported by an election court for bribery at a Parliamentary election, the Board make the following somewhat astonishing comment: "We consider that Poor-law medical officers, owing to the nature of their duties and responsibilities, should act with respect to the election of Members of Parliament with the same degree of reserve that members of the permanent Civil Service observe at such elections, and that they should refrain from interfering in such contests beyond exercising any statutory right to vote they may possess. A similar line of conduct should, we think, be followed by medical and other Poor-law officers in connexion with the local elections for Poor-law guardians and councillors."

Only one case of small-pox occurred during the year. There were several outbreaks of typhus fever in the counties Galway and Clare, and several cases occurred in the towns of Waterford, Dublin, Galway, and Arklow. In the causation of enteric fever milk had a prominent part. In Dublin last winter, 50 cases were definitely connected with the milk-supply of two inter-related dairies. Two outbreaks in the north of Ireland were traced by Dr. B. O'Brien to carriers. In 1908 the Local Government Board promulgated the "Dairies, Cowsheds, and Milkshops Order," designed to safeguard the health of the community from insanitary milk supplies. In only 244 out of 309 sanitary districts have any steps been taken to obey the terms of the Order.

The Board notes with regret the retirement from its inspectorships of Surgeon-Colonel D. Edgar Flinn, who was appointed Chief Inspector of Industrial Schools and Medical Member of the Prisons Board, and of Dr. C. J. Clibborn, under the 65 rule. Their places have been filled by Dr. C. J. MacCormack and Dr. Brian O'Brien.

Belfast and the late Sir Robert Hart.

It is with deep regret that Belfast has learned the death of Sir Robert Hart. In many respects he was by far the most remarkable Ulsterman of the last century; indeed, his romantic career is only equalled by that of Sir Hans Sloane, the founder of the British Museum, who came from the same province, and who was a member of the medical profession. Born in 1835 at Portadown, Sir Robert Hart was a brilliant student of Queen's College, Belfast, and in 1854 he joined the British Consular service in China, and in 1863 was appointed inspector-general of foreign customs and took up his duties at Peking. From this time forward his career is history and need not be recapitulated here. It is enough to say that no foreigner ever wielded such influence as he did in China, and no person ever occupied a more important position in the East than did this brilliant Irishman. Sir Robert Hart married in 1866 a daughter of Dr. Alexr. Bredon, a well-known medical man who practised in Portadown. In 1908 he revisited Belfast and received the freedom of the city. He was a pro-Chancellor of the Queen's University of Belfast, and now, owing to his death, as well as to the decease of Judge Shaw, who was appointed pro-Chancellor in the place of Sir Donald Currie, one of the four who occupied that position only one is left, Lord Pirrie, K.P. It is a remarkable fact that Ulster has contributed three ambassadors to China (in addition to Sir Robert Hart, who was not during the greater part of his career in the English service): Lord Macartney, the first ambassador; Sir Henry Pallinger, Bart.; and Sir John Jordan, who is now the *doyen* of all the diplomatic representatives in Peking, and who was only two years old when Sir Robert Hart, in 1854, entered the consular service in China. Like Sir Robert Hart, Sir John Jordan is an honorary freeman of the city of Belfast.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Drinking Water of Paris.

IN a previous letter[1] I referred to the difficulties encountered each year by the city of Paris in furnishing its inhabitants during the hot spells with an adequate supply of pure drinking water. I called attention especially to the suffering that has been occasioned by the lack of water this year. If, however, as the season passes, the immediate preoccupation with the matter is relaxed, the proper authorities have not lost sight of it, but are giving it their continued attention. The best means of disposing of this problem with the most satisfactory results consists of leading new water sources into the capital. Recently water has been taken from Lake Geneva for analysis with this end in view. On the other hand, at a meeting of the Council of Hygiene Dr. Chantemesse, member of the Academy of Medicine and a professor of the Faculty of Medicine, read a letter from the Prefect of the Seine, who stated that a preliminary project was under consideration for a supply from the sources of the Voulzie, the Dutreint, and the Dragon. This plan would increase the supply of potable water by from 65,000 to 70,000 cubic metres daily. After the reading of this letter Professor Chantemesse, in a report thereon, formulated conclusions favourable to the adoption of this plan, and after some discussion the report was adopted.

Deaths of Dr. Courtault and Dr. Brouardel.

Some years ago an interesting medical enterprise was established under the title of the *Maison des Médecins*, concerning which I have already written. The president was Dr. Courtault. This new enterprise, which already is working well, has recently sustained a great loss in the person of its president. Dr. Courtault was very fond of the sea, and was taking a voyage as ship's surgeon on board the *Emir*. After a trip to Algeria the vessel was spending an evening at Gibraltar, when, during the night, the *Emir* was run into by the *Silverton* and sank in 700 metres of water in a minute. Dr. Courtault perished immediately. The medical profession has been saddened also by another death, in this case

[1] THE LANCET, August 12th, 1911, p. 428.

that of a martyr to professional duty. Dr. Louis Brandet, professor of anatomy at the Medical School of Rheims, contracted from one of his patients a malignant anthrax of so severe a nature that he succumbed.

The Crusade against Tuberculosis in the Marine.

The fight against tuberculosis, a disease that reaps annually a large number of victims among seamen, needs pursuing in the interests not only of the patients themselves, but still more in those of the ship's crew as a whole. The Minister of Marine, M. Delcassé, has appointed a commission to inquire into all the means of arresting the progress of tuberculosis among both the ships' crews and the workmen in the naval depôts. Modern ships with their excess of warmth in the cabins are foci of pulmonary congestion and consequently of tuberculosis. It is the same in the arsenals, the construction of which is for the most part antiquated and devoid of any reference to hygienic principles. The sea services are to be rigorously barred to the tuberculous; persons attacked with the disease will either be sent to their homes or isolated. The existing sanatorium at Trébéron, near Brest, is reserved for patients coming from northern ports, and the construction of a similar institution in the south is under consideration to receive those patients coming from Toulon or Rochefort. As to the incurables, the Marine Service will ask from Parliament power to grant them in a comprehensive measure either proportionate pensions or assistance.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Syphilitic Affections of the Heart.

AT the last meeting of the Berlin Medical Society before the summer vacation Dr. Breitmann of St. Petersburg read a paper on Syphilitic Diseases of the Heart and their Treatment. He said that syphilis of the heart had no specific symptoms, but that the combination of certain symptoms and the mode of their development were characteristic. According to him the following manifestations made a syphilitic affection very likely: (1) rapid development of cardiac disease without pyrexia or other acute symptoms; (2) enlargement of the cardiac dulness and hypertrophy without an obvious cause; (3) the existence of a severe affection of the heart simultaneously with the absence of valvular symptoms, œdema, or pain; (4) early development of arterio-sclerosis; (5) the presence of other syphilitic symptoms, such as exanthemata or gumma, together with the cardiac affection; (6) a positive Wassermann reaction; and (7) the good result of specific treatment. The diagnosis of syphilis of the heart is of great importance, because treatment commenced in good time gave excellent results, whilst a delay might lead to early death. Sudden death was observed by Dr. Breitmann in from 33 to 50 per cent. of the cases, especially after bodily exertion or over-indulgence in alcohol. Endarteritis was frequently present in those cases. Every case of angina pectoris during the younger period of life was open to the suspicion of syphilitic origin. With respect to treatment, Dr. Breitmann said that the first thing to be done was to strengthen the heart; narcotics, anæsthetics, hydrotherapy, massage, and every form of treatment requiring exertion should therefore be avoided. In sclerosis of the coronary arteries the administration of digitalis might be directly fatal. The development of troubles of the circulation in syphilitic diseases of the heart must be combated by mercurial treatment, which usually made the threatening symptoms disappear; afterwards the administration of iodine was necessary. Salvarsan having a tendency to weaken the action of the heart was absolutely contra-indicated in syphilitic diseases of that organ. In sclerosis of the coronary arteries and in myocarditis cardiac failure might follow the administration of salvarsan.

The Indications of the Wassermann Reaction in the Treatment of Syphilis.

At the same meeting of the society Professor Plehn, physician to the Urban Hospital in Berlin, read a paper on the practical application of the Wassermann reaction in the treatment of syphilis, especially in the tertiary form. He said that in order to test the efficacy of the Wassermann reaction it had been performed in 200 cases under his care, the patients including not only persons suspected to be syphilitic, but also others suffering from a variety of diseases, such as rheumatic affections, arterio-sclerosis, nervous diseases, &c. In 139 of these cases there was no previous history of syphilis, and the reaction in these cases was negative. In seven cases, however, the reaction on being made several times was alternatively positive and negative without any antisyphilitic treatment. In two of the cases there was a history of chancre, but there were no discoverable syphilitic symptoms, the patients having been brought to the hospital for an apoplectic seizure and for neuralgia of the trigeminus nerve respectively. In one case the post-mortem examination did not show any sign of syphilis, although there had been a well-marked positive Wassermann reaction; on the other hand, in four cases syphilis was recognised at the post-mortem examination, although the reaction had been negative. Of nine patients, aged between 55 and 75 years, without any suspicion of syphilis in their history and without symptoms of that disease, the reaction was negative in five and positive in four cases. With respect to diseases of the central nervous system Professor Plehn said that of three tabetic patients having no history of syphilis two gave a negative and one a positive reaction. Of four tabetic patients with a syphilitic history three gave a positive and one a negative reaction; the blood of four patients with general paralysis gave a negative reaction, but the cerebro-spinal fluid of one of them gave a positive reaction. Of two patients with tabo-paralysis one admitted but the other denied having suffered from syphilis. In all these cases the reaction was repeated six times, always with the same result. Patients suffering from arterio-sclerosis gave in the majority of cases a negative reaction. Professor Plehn expressed the opinion that in cases where the Wassermann reaction had been positive, although neither manifest syphilitic symptoms were present nor was there any history of syphilis, the explanation was that syphilitic infection had taken place at some former time, but with symptoms so insignificant that the patient had not noticed it, and that the disease had subsided without any treatment. Spontaneous recovery from syphilis was more frequent, he said, than was believed. The opinion that syphilis remained in the active state as long as the Wassermann reaction was positive, and that the treatment must be continued till the reaction became negative, was an error; a negative reaction obtained after antisyphilitic treatment might again become positive and a negative reaction did not always mean a definitive recovery. On the other hand, the reaction might be always positive without any concurrent clinical phenomena, so that a positive reaction did not prove the syphilitic nature of suspected symptoms. Professor Plehn concluded that the utmost precaution was necessary in using the Wassermann reaction for differential diagnosis, because the results obtained were often misleading, and it must never by itself be accepted as an indication either for or against specific treatment, except in the early stages of the disease.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

The Public Health Exhibit at the Toronto Exhibition.

UNDER the direction and management of Dr. W. S. McCullough, chief health officer of Ontario, an excellent public health exhibit was held at the recent Toronto annual exhibition. This was a development of the travelling tuberculosis exhibit which was established by the Ontario Board of Health some few years ago. The exhibit this year embraced a large variety of subjects, and although the space allotted was limited the display was remarkably good. The Provincial Board of Health of Ontario showed a collection of well-mounted photographs of sanatoriums in Great Britain, Germany, Scandinavia, the United States, and Canada, together with models of tents, sanatoriums, and huts for the care of consumptives. The Toronto Health Department displayed charts, banners, and literature. Perhaps the outstanding feature of the exhibit was the contribution of the United States, and

especially the charts and mechanical models lent by the Department of Health of Chicago. Dr. C. St. Clair Drake of Chicago, the designer of the models, was in charge. The first model was illustrative of infant mortality in Chicago, and took the form of a revolving cylinder worked by clockwork. A succession of dolls appeared, and every fourth doll was destroyed by a figure representing the Angel of Death. Another model illustrated ventilation and its lack. Two rooms of the same size were shown in which were dolls in beds. By means of an ingenious contrivance vapour was seen to issue from the noses of the dolls at the ordinary breathing rate. One of the rooms had its doors and windows open and the atmosphere remained clear, while in the other room, where windows and doors were closed, the air was soon seen to be quite thick. These models excited great interest and thus the desired object was attained. It was instructive to listen to the questions and comments of the crowd of women who continually surrounded these practical demonstrations during the exhibition. In a commodious theatre, situated in the women's building, a series of health talks was given daily by men and women versed in preventive medicine. The lectures were illustrated by pictures on a screen, showing good and faulty milk conditions, the danger of flies, &c. Among the lecturers were Dr. Charles Hastings, Dr. Helen MacMurchy, and Dr. Connell of Kingston. Great interest was manifested in these lectures, and such instruction of the general public in the causes and modes of prevention of disease should bear good fruit.

Hospitals of Toronto.

The buildings of the new General Hospital of Toronto are being proceeded with rapidly. The administrative block and the surgical and medical wings which face College-street are externally nearing completion, and the façade is imposing and workmanlike if not altogether a thing of beauty. It is stated that the pathological wing will be completed and ready for occupation on Oct. 1st. The new Western Hospital on Bathurst-street is rapidly approaching completion; so also is the addition to St. Michael's Hospital, which will more than double its in-patient accommodation. The city of Toronto is about to construct a large modern isolation hospital. Lastly, a private hospital with ample accommodation will soon be opened.

Resignation of Dr. Charles Sheard.

Dr. Charles Sheard, who recently resigned the medical officership of health of Toronto, has now also resigned the professorship of preventive medicine in the Medical Faculty of Toronto University. Dr. Sheard had been a lecturer at the University since 1882, and as an exponent of public health matters his experience and ability enabled him to put his knowledge into clear and forcible language.

Sept. 19th.

NOTES FROM SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

The New Union Health Organisation.

THE names of the health officers for the Union have now been announced. Dr. F. A. Arnold is appointed medical officer of health for the Union, stationed at Pretoria; and Dr. J. A. Mitchell, Dr. L. G. Haydon, and Dr. P. T. Adams the assistant medical officers, stationed respectively at Cape Town, Durban, and Bloemfontein. Dr. Arnold entered the service of the late Transvaal Government in 1905, when he was appointed a district medical officer and shortly afterwards assistant medical officer of health for that colony. He became medical officer of health in January, 1910, in succession to the late Dr. Walker. Dr. Mitchell has been the assistant medical officer of health for Cape Colony since 1901, Dr. Haydon the assistant port health officer, Durban, since 1904, and Dr. Adams the assistant medical officer of health, bacteriologist, and analyst for the Orange River Colony since 1903. The profession in South Africa will extend its cordial congratulations to these officers on their new appointments, though it can hardly fail to continue its opposition to the Ministerial policy which these appointments imply. Ever since the retirement on pension of Dr. George Turner, the medical officer of health for the Transvaal has been purely an advisory officer, and the actual administration of public health in that colony has been relegated to a comparatively junior clerk in the department of the Colonial Secretary and, since Union, of the Interior. It is public knowledge that the appointment has been a sinecure without any real work or responsibility. It is feared that this will be the case also with the new appointment of medical officer of health for the Union. In any event, in his new capacity Dr. Arnold will hardly ever be able to leave his headquarters and to get into touch with the needs of the country or even of the province in which he is stationed, and the same remark applies also to the assistants. Thus Dr. Mitchell has been appointed also the administrator of the Food and Drugs Act in the Cape Province, work which, though probably trifling in amount, would seem effectually to prevent him from travelling. Dr. Haydon is apparently to continue his port health duties, and Dr. Adams is to continue in charge of the bacteriological and analytical laboratory at Bloemfontein. These officers therefore will obviously not be available for many public health duties outside the respective towns in which they are stationed. It is understood that the assistant medical officers are not to be under the control of Dr. Arnold, but will each be directly responsible to the lay officials in the Department of the Interior. Moreover, the work is to be concentrated at Pretoria, to which all communications on public health matters, including the returns of notifications of infectious diseases by local authorities, have now to be addressed, in direct violation of existing laws. In other words, the Government has adopted a system of administration which, besides being illegal in certain provinces, has been condemned by leading men, commissions, public bodies, and the medical profession in South Africa after prolonged trial, and seems in bringing such system into operation to have deliberately tied down the technical officials to the towns in which they are stationed, so as to prevent them from undertaking useful and urgently needed work at other centres.

The Census Returns.

The unaudited figures for the Census of the Union were published a few days ago in the form of a Government Blue-book. An examination of these figures shows that the population has increased by 15·12 per cent. since the Census in 1904. Europeans have increased by 14·44 per cent., natives by 16·19 per cent., and all other coloured races by 9·84 per cent. The total other than European population has increased by 15·31 per cent. during the septennium. Whilst the latter rate may be said to represent almost entirely the natural rate of increase amongst the coloured races, this cannot be stated of the European rate, for in this case the figures are vitiated by the effects of immigration and emigration. Unfortunately, no steps can be taken for ascertaining the exact rate of the natural increase in Europeans, for the immigration and emigration statistics are quite unreliable. It is believed, however, that the emigration has far exceeded the immigration during the period. In 1904 in the territories of the Union the white population numbered 21·58 per cent. of the whole. This position has been practically maintained, for on May 7th the European population numbered 21·45 per cent. of the whole. In other words, the white man has barely maintained his position in South Africa. From this point of view it was inevitable that the Cape returns should prove the least satisfactory of the four provinces, for the prolonged depression was undoubtedly felt most acutely at the Cape, and during the period of retrenchment a very large number of people emigrated. Moreover, the revival of industrial activity on the Rand took place before the effects of the depression had passed away, and naturally there was an exodus from centres where employment was hard to obtain to the centre where there was a demand for labour. In the Cape Province the white population shows a growth of only 3436, or 0·59 per cent., while the total coloured population has increased by 149,784 persons, or 8 18 per cent. Natal for similar reasons has remained almost equally stagnant in respect of its white population, which has increased merely by 1473 persons, or 1·52 per cent., while the total coloured population in this province has increased by 81,731, or 8·08 per cent. The Transvaal population now numbers a European population of 420,831, an increase of 41·56 per cent., and the Free State has increased its white inhabitants by 22·96 per cent. to 175,436. The other than European population in these two provinces have increased 29·11 and 43·67 per cent. respectively.

The figures for the two sexes show that the females

within the Union have increased somewhat more than the males, the latter having increased since 1904 by 14·44 per cent. as compared with 15·85 per cent. in respect of the former. Thus the number of females in the Union to every 100 males is now 94·11 as compared with 92·97 in 1904. European males have, however, only increased 8·08 per cent. as compared with 22·81 per cent. the rate of increase for European females. In the case of the other than European population, however, the rate of increase has been 16·42 per cent. for males and 14·19 per cent. for fema'es. The number of females to every 100 males in the Union is for Europeans 86·18 per cent. as compared with 75·84 in 1904, and for other than Europeans 96·40 per cent. as compared with 98·28 per cent. in 1904. But when one comes to examine the figures for the four provinces it is seen at once how the depression in trade has operated on the Coastal Provinces. Thus in the Cape of Good Hope the European male population has actually diminished by 16,825, a decrease of 5·28 per cent., and in Natal by 3927, or 6·92 per cent. In these provinces European females increased by 7·76 and 13·38 per cent. respectively. On the other hand, in the Transvaal and Free State the European male populations increased by 33·12 and 15·99 per cent., and the European female populations by 54·2 and 32·25 per cent. respectively. And in the Cape and Natal the other than European male populations only show an increase of 6·04 and 4·23 per cent. as compared with the corresponding rates of increase for females of 10·27 and 11·75 per cent. respectively. In the Transvaal the rate of increase has been for coloured males 39·13 per cent., and coloured females 17·38 per cent. In the Orange Free State the rate of increase for coloured males has been 43·29 per cent., and for coloured females 44·09 per cent. The number of females to every 100 males in the Cape of Good Hope is for Europeans 93·28, as compared with 82·00 in 1904, and for the coloured races 107·37, as compared with 103·25 in 1904. In Natal, for Europeans 86·6, as compared with 71·09 in 1904, and for the coloured races 112·41, as compared with 104·84 in 1904. In the Transvaal the proportion is for Europeans 77·35, as compared with 66·78 in 1904, and for the coloured population 72·14, in contrast to the proportion in 1904, when it was 85·51. In the Free State the proportion is 85·42 for Europeans, as against 74·91 in 1904, and 90·85 for coloured, as compared with 90·34.

The changes which have taken place in the European populations are largely accounted for, as already stated, by the depression in the Coastal Colonies and the fact that the mining areas in the inland colonies are becoming more and more settled communities. The emigration of Europeans from the Cape and Natal was largely amongst unmarried men, whilst besides the large influx of European males to the mining areas there was a proportionately greater immigration of European females. The changes in the sex composition of the coloured populations of the four provinces are, of course, explained by the fact that very much larger numbers of coloured males from the Cape and Natal are now working on the Transvaal mines than was the case in 1904. As far as particular areas are concerned, it is of interest to note that in the Cape Peninsula (excluding Simonstown) the total European population decreased by 20,233, or 17·92 per cent., and that the coloured population increased by 6412, or 7·23 per cent., resulting in a net decrease in the total combined population of 13,821, or 6·86 per cent. On the other hand, the European population of the Witwatersrand increased by 72,624, or 60·25 per cent.; whilst the coloured population of this area increased by 150,218, or 99·58 per cent. The following table shows the population of the different provinces of the Union on May 7th last, viz. —

Province.	European.	Native.	Other coloured.	Total.
Cape of Good Hope	583,177	1,545,308	434,539	2,563,024
Natal	98,582	951,808	141,568	1,191,958
Transvaal	420,831	1,224,155	31,625	1,676,611
Orange Free State	175,435	339,811	11,660	526,906
Total	1,278,025	4,061,082	619,392	5,958,499

Johannesburg Hospital.

The management of the Johannesburg Hospital has recently come in for a good deal of criticism in the lay press, and in particular allegations have been made of undue delays in the attending to casualty patients. These were investigated by a committee appointed by the board of management, which reported that the complaints were without foundation. At the same time, however, it has been recommended, and the board has agreed, that two wards in the main block should be appropriated and converted to the uses of a casualty ward and receiving room with necessary offices. It would thus seem as if there may after all have been some justification for the newspaper crusade against the hospital. It is understood that the authorities at this hospital have agreed to take in insane patients from Oct. 1st, the date when the new Prisons and Reformatory Act comes into operation. In this Act it is, *inter alia*, provided that into no jail of any district in which there is a public hospital or asylum shall any lunatic or alleged lunatic be admitted. Hitherto all such cases, if not kept under observation in their own homes pending removal to the asylums, have been detained in the jail hospitals. In view of the new Act the Government has approached hospital boards with the object of getting such patients received into the hospitals. Nearly all the hospital boards have refused point-blank to have anything to do with such patients on the ground of lack of accommodation. It is not known whether the board of the Johannesburg Hospital intends to provide special accommodation or whether it proposes to treat merely selected cases in the general wards of the institution. The great and pressing need throughout the Union is for more asylum accommodation, as for many years past grave delay has occurred in removing patients to the asylums after certification, and this has been due solely to lack of accommodation. It is satisfactory to note that the question of enlarging the asylums is now receiving attention.

August 29th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

The Kasauli Pasteur Institute.

THE tenth annual report of the Kasauli Pasteur Institute, relating to the year 1910, states that the number of persons treated was 2073, a higher figure than in any year since the opening of the institute in 1900. The percentage of failure in treatment was 0·19; the lowest percentage of failures previously had been 0·36 in 1908. It is true that 26 deaths occurred from hydrophobia among the cases treated, but 14 of these died during, and 8 within 15 days of completion of, treatment; only the 4 cases that died later than 15 days after completion of treatment are accounted to be failures. The institute completed the first ten years of its existence on August 9th, 1910; Major W. F. Harvey, I.M.S., very opportunely therefore presents us with a review of the changes which have taken place in anti-rabic treatment and in some of our conceptions regarding the disease. The most important of these has been the substitution of the method of Högyes (that is, the injection of high dilutions of "living and virulent" virus at first, followed by gradually diminishing dilutions) for Pasteur's original "dried cord" method (that is, commencing the treatment with a dead virus and following it up with an attenuated living virus). Further, by the employment of Negri's method of microscopic diagnosis in brain tissue the necessity for using animals as tests for the presence of the virus has been almost entirely done away with. In considering the factors that make for fatality the depth of the wound is one of importance; of the 26 fatal cases, 22 were bitten deeply and 4 only were superficial bites. Interposition of clothing is, of course, a great protection; all the fatal cases but one were bitten on the bare skin, and in this one case the clothing was torn. Cauterisation, if done quickly and thoroughly, is able to avert infection; of the 26 fatal cases, 18 had been either not cauterised at all or with an inefficient caustic, or later than one hour after the bite. As to the proper measures for the prevention of rabies in India, where extermination of the contagion is impossible, Major Harvey holds that the true prophylaxis begins with

the rabid animal. For the European officer class he lays down three injunctions: (1) let no one allow his own or his friend's dog to lick him; (2) let no one allow his dog to sleep on his bed; and (3) let everyone treat a sick dog as if he were a rabid dog. For the protection of other classes of the population he advocates the registration of dogs and their muzzling for, say, three months at a time. This would be, indeed, an Augean task. Local treatment with pure carbolic acid thoroughly applied at once, or the application of a Bier's bandage above the part bitten (so as to cause congestion), or of a Bier's vacuum glass, or cauterisation, are recommended. In Great Britain, thanks to the energy and determination of Mr. Walter Long, any dread of hydrophobia has ceased; in India, we fear, it can never be exterminated; but since the establishment of Pasteur institutes the cause for anxiety has been greatly diminished. If Sir David Semple's method of using a vaccine prepared from a killed virus and diluted with carbolised saline solution[1] be adopted, the necessity for travelling long distances to the Pasteur institutes would be done away with and the patient could be treated without delay. In any case the work of the Kasauli Institute will stand out as one of the most beneficent of the results of British rule in the sphere of prevention of disease. It is most gratifying to see announcements of liberal contributions from the Maharajahs of Gwalior, Benares, and Patiala, and from other native rulers, as well as from many municipalities towards the erection of new buildings, including accommodation for all classes of Indian patients, at Kasauli; it is evidence that the work of the institute is thoroughly appreciated.

Septic Tank Latrines.—Accidents in Factories.

The use of these is extending, and they appear to work satisfactorily in the tropical climate of Bengal. A recent report reminds us that they are not without dangers. An explosion occurred in the septic tank at the Kankinara jute mills last winter; it had been closed for purposes of cleaning. About 1 A.M. a party of eight sweepers came to examine the tank and introduced a naked light into the manhole; this was immediately followed by an explosion. Two men were killed outright, the remaining six were badly injured, and the building was completely wrecked. There was a considerable increase in factory accidents during the year, 1235 compared with 957 in the previous year; 77 were fatal.

Bengal Water-supply.

Local self-government is carried out in Bengal through the medium of district boards. These authorities are not always inclined to devote much expenditure to matters affecting health, in which respect they are not very unlike local sanitary authorities in other parts of the world. Attention has been called to the necessity for improving the water-supply in certain areas, but without leading to any action in consequence; whereupon it is noted that unless local bodies will of their own initiative pay greater attention to this important item of administration, the Bengal Government will have no alternative but to earmark for this purpose a portion of the grants made to district boards, as it is impossible to acquiesce in the persistent disregard of the instructions in this matter.

Sept. 6th.

[1] See THE LANCET, July 15th, 1911, p. 173.

LISTER INSTITUTE OF PREVENTIVE MEDICINE.—Mr. Major Greenwood, jun., F.S.S., statistician to the Institute, will begin a course of lectures and demonstrations on "Statistical Methods and their Applications in Preventive Medicine and Pathology," on Monday, Oct. 16th, at 5 P.M. The lectures will deal with the aims of statistical science and the classes of problems to which its methods can be applied; the study of variation and the commonly observed types of frequency distribution; associated or correlative variations, and methods employed in their quantitative study; errors of sampling, outline of the theory and its practical applications. This course is open, without fee, to all medical men and to others interested in the subject. Further particulars, together with information as to the conditions under which those desirous of undertaking research work in medical statistics are admitted to the institute's laboratory, can be obtained on application to the secretary of the governing body, Lister Institute of Preventive Medicine, Chelsea Bridge-road, London, S.W.

Obituary.

FREDERICK WILLIAM PAVY, LL.D. GLASG., M.D. LOND., F.R.C.P. LOND., F.R.S.,

CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

Frederick William Pavy, who died at his residence, 35, Grosvenor-street, W., on Sept. 19th, in his eighty-third year, was born at Wroughton, Wiltshire, on May 29th, 1829. He was educated at Merchant Taylors' School. He proceeded thence in 1847 to Guy's Hospital. In 1852 he took the M.B. of London University, gaining honours in physiology and comparative anatomy, surgery, obstetric medicine, and medicine, in which last-named subject he was also medallist. In the following year he proceeded to the M.D. degree. After serving as house surgeon and house physician at Guy's Hospital he went to Paris to continue his studies, where he came into contact with Claude Bernard, then at the height of his fame. In 1854 he was appointed a lecturer on anatomy at Guy's Hospital. In 1856 he became lecturer on comparative anatomy, physiology and microscopical anatomy at the same school, holding the former post until 1864, when he relinquished it to Dr. P. H. Pye-Smith, who also succeeded him in 1877 in the lectureship on physiology. In 1859 he was appointed assistant physician at Guy's, and a lecturer on clinical medicine during the summer session. In this year he published in the *Guy's Hospital Reports* a paper on Lesions of the Nervous System producing Diabetes, thus identifying himself with the special subject in medicine with which his future career was to be so closely associated. In the same year he delivered the Lettsomian lectures on Certain Points Connected with Diabetes. These lectures were published in THE LANCET in November and December, 1860, and show very well how scientific was the spirit in which Pavy was approaching great scientific problems. In the same year he was elected a Fellow of the Royal College of Physicians of London, and in 1861 his first communication was made to the Royal Society, in which he detailed his researches on sugar formation in the liver; this paper was published in the society's Philosophical Transactions for that year. He delivered the Goulstonian lectures on Assimilation and the Influence of its Defects on the Urine in 1862–63.[1] These lectures were published in full in THE LANCET, and, taken in conjunction with contributions to the Guy's Hospital Reports on allied subjects, marked their author out, while still a young man, as a leader of thought in the profession. In 1872–73 he became an examiner at the Royal College of Physicians, which function he again fulfilled in 1878–79. He was a councillor of the College for 1875–77 and again for 1888–90. In 1871 he was appointed full physician to Guy's Hospital, and Lecturer on Medicine at its medical school, holding these offices until 1890 and 1886 respectively. In 1878 he delivered the Croonian lectures before the Royal College of Physicians of London, choosing for his subject Certain Points Connected with Diabetes.[2] These lectures were subsequently published in book form, and the clearness and terseness with which the observer stated his views, and the dignified moderation with which he has answered the objections raised against them, established him firmly in the good opinion of the scientific members of the medical profession.

In 1882–83 Dr. Pavy became Censor of the Royal College of Physicians, an office which he again held in 1891. In 1886 he was Harveian Orator of the Medical Society of London, his oration being published in our columns on Oct. 23rd. In 1888 he received the honorary degree of LL.D. at Glasgow University. In 1890 he passed on to the consulting staff at Guy's Hospital. On Oct. 8th of that year he formally handed over to the gymnasium committee of the Guy's Hospital Students' Club the gymnasium generously built and equipped by him for their benefit. He was President of the Royal Medical and Chirurgical Society in 1893, and in 1894 he was again Croonian lecturer of the Royal College of Physicians of London, while in 1897 he delivered a Supplementary Croonian lecture on Points Connected with the Pathology and Treatment of Diabetes, which was published in THE LANCET of Nov. 20th and 27th. In

FREDERICK WILLIAM PAVY, LL.D., M.D., F.R.C.P., F.R.S.

(Reproduced from a photograph by Messrs. Maull and Fox.)

1901 he was awarded the Baly gold medal by the Royal College of Physicians for his distinguished work on Physiology. In 1908 he delivered before the Royal College of Physicians some lectures on the Pathology and Treatment of Diabetes Viewed by the Light of Present-day Knowledge. These lectures also were published in our columns, and contain his last pronouncements on the subject that he had made his life-long study. In 1909 Dr. Pavy became a Lauréat de l'Académie de Médecine de Paris, receiving the Prix Godard for his physiological researches.

In 1909 also fell his eightieth birthday, which was commemorated by the medical profession in a marked manner. It was generally recognised that Pavy was among the best known and most learned of our physicians and physiologists, while despite the weight of years he was maintaining himself in the van and fighting for truth as keen and vigorous a battle now as ever he did when he was winning his spurs over 50 years earlier. The Physiological Society at its meeting at Oxford on June 26th chose the occasion to pay him honour, for Professor F. Gotch then presented to him on behalf of the society a silver bowl in token of affection and admiration.

Dr. Pavy's learning was widely recognised throughout the medical world, as is shown by the honorary distinctions conferred on him by his medical *confrères* in foreign lands. He was a corresponding member of the Société d'Anatomie de Paris, of the Medico-Chirurgical Society of Edinburgh, and of the Verein für Innere Medizin of Berlin, and a Corresponding Fellow of the Pathological Society of Montreal; an honorary member of the Philadelphia County Medical Society, a foreign honorary member of the Royal Academy of Medicine of Belgium, and a Member (and former Vice-President) of the Paris Medical Society. His distinguished physiological work gained him the Fellowship of the Royal Society. He was President of the Association for Advancement of Scientific Research and Chairman of the National Committee of International Medical Congresses.

Dr. Pavy's literary work was both voluminous and important. It was mainly devoted to the physiology of digestion and the subject of diabetes. In addition to the lectures and contributions to medical literature already named he was the author of the following books: (1) "Researches on the Nature and Treatment of Diabetes" (1862), which reached its second edition in 1869. (2) "A Treatise on the Function of Digestion; Its Disorders and their Treatment" (1867). This work also reached its second edition in 1869. (3) His "Treatise on Food and Dietetics," published in 1874, and reaching a second edition in the following year, received a hearty welcome from the medical profession. Definite pronouncements from the pen of one who had devoted so much attention to his subject, and who was so high a scientific authority on all questions relating to digestion and assimilation, were sure from the first of the circulation which it deserved. Not pretending to contain much original research, the book presented an admirably clear, full, well-digested account of all-important facts and theories on the supply of force and material to the human organism. (4) "The Physiology of the Carbohydrates, their Application as Food and Relation to Diabetes," was published in 1894. (5) His last work, which was on "Carbohydrate Metabolism and Diabetes," was published in 1906, and like all the author's writings on the subject of carbohydrate metabolism and diabetes proved of interest and importance to students of a fascinating problem, embodying the views of one who had devoted his life's work to this branch of physiology and pathology, and who had pursued the path of investigation with exemplary diligence and pertinacity. Dr. Pavy's antagonism to the theory of glycogenesis as usually held was shown by his rapid departure from this theory to the enunciation of his own position, that so far from the passage of absorbed carbohydrate from the intestine to the liver being a normal process it is only when an undue amount of sugar is present in the alimentary canal that it reaches the portal system at all.

As an extraordinary proof of the concentration of Pavy's interests we reproduce here the titles of a few of the principal communications that have appeared in our own columns from his pen, excluding lectures and others that have been already mentioned. They are: "On a case of Cholera," THE LANCET, August 5th, 1865; "Paroxysmal Hæmaturia," THE LANCET, July 14th, 1866; "Hydatid of Liver, Treated Successfully by the Injection of the Extract of Male Fern into the Cyst," THE LANCET, Sept. 1st, 1866; "On the Alleged Efficacy of the Peroxide of Hydrogen and Ozonic Ether as Remedial Agents in Diabetes Mellitus," THE LANCET, March 13th, 1869; "Contributions on the Physiology and Therapeutics of Food," THE LANCET, Dec. 2nd, 16th, 23rd, 1871, Jan. 13th, 27th, Feb. 10th, and March 23rd, 1872; "The Effect of Prolonged Muscular Exercise upon the Urine in Relation to the Source of Muscular Power," THE LANCET, Nov. 25th, Dec. 9th, 16th, 23rd, 1876, and Jan. 13th, 1877; "A New Method for the Quantitative Determination of Sugar in Blood," read before the Royal Society, June 14th, abstract in THE LANCET, July 7th, 1877; "The Physiology of Sugar in Relation to the Blood," read before the Royal Society, June 21st, 1877, THE LANCET, July 14th, 1877, p. 53; "A New Line of Research Bearing on the Physiology of Sugar in the Animal System," read before the Royal Society, June 8th, 1881, THE LANCET, July 2nd, 1881; "Introductory Note on the Physiology of the Carbohydrates in the Animal System," read before the Royal Society, April 12th, 1883, THE LANCET, April 21st, 1883; "On the Physiology of the Carbohydrates in the Animal System," read before the Royal Society, Dec. 20th, 1883, THE LANCET, Jan. 5th, 12th, 19th, 26th, Feb. 2nd and 9th, 1884; "On the Quantitative Determination of Sugar for Clinical Purposes by the Ammoniated Cupric Test," THE LANCET, March 1st, 1884; "On Cyclic Albuminuria (Albuminuria in the Apparently Healthy)," read in the Section of Medicine, British Medical Association (Cardiff), 1885, THE LANCET, Oct. 17th, 1885; "Introductory Address to the Discussion on the Clinical Aspect of Glycosuria," read in the Section of Medicine, British Medical Association (Cardiff), 1885, THE LANCET, Dec. 5th and 12th, 1885; "Ferrocyanic Test Pellets for Albumin," THE LANCET, June 13th, 1885; "A Further Contribution on Cyclic Albuminuria, with Observations on the Effect of Various Conditions upon the Diurnal Appearance of the Urine," THE LANCET, March 6th, 1886; "Cyclic Albuminuria," THE LANCET, April 14th, 1888; "On the Diagnosis of Cases of Albuminuria, with special reference to Life Insurance," THE LANCET, August 24th, 1889; "On the Principles of Treatment of Diabetes Mellitus," read at the International Medical Congress, Berlin, 1890, abstracted in THE LANCET, August 16th, 1890; "Differentiation in Diabetes," THE LANCET, June 16th, 23rd and 30th, 1900; "On the Acetone Series of Products in connexion with Diabetic Coma," THE LANCET, July 12th, 19th, 26th, August 9th, 1902; "On Diabetic Neuritis," THE LANCET, July 2nd and 9th, 1904; "Lectures on Carbohydrate Metabolism," delivered at the University of London, THE LANCET, June 24th, July 1st, and August 5th, 1905; "The Pathogeny of Diabetes," read at the Fifteenth International Congress of Medicine (Lisbon), April, 1906, THE LANCET, May 5th, 1906; "A Study of the Conditions producing the Anomalous Reaction not infrequently met with on Testing Urine for Sugar with Fehling's Solution," THE LANCET, July 27th and August 3rd and 10th, 1907.

What was exactly the scientific position of this distinguished man? In the first place his labours form a connecting link between the past and the present. He was the last survivor of a line of distinguished physician-chemists who in this country, during the earlier and middle years of the last century, did much to lay the foundations and advance the study of metabolic disorders. He was a worthy successor of Prout, Alexander Marcet, Bence Jones, and Golding-Bird, and a contemporary of William Marcet, Roberts, Garrod, and Thudichum; but he also ranks as a pioneer among the chemical pathologists of the modern school, who, in the light of a far more ample chemical science, and by methods far more exact and adequate, are carrying on, in Europe and in America, the work which those men initiated, and are expanding it in all directions. A pupil of Claude Bernard, Pavy realised to the fullest extent the truth that all advances in the study of disease must rest upon investigations into the normal processes of the body, and his memory is reverenced by physiologists, pathologists, and physicians alike. We associate with his name the recognition of postural albuminuria, and the theory that the living gastric wall owes its immunity from auto-digestion to the alkalinity of the blood; but it is chiefly in connexion with the study of carbohydrate metabolism that his name and work will be

remembered. He was the founder of the modern study of diabetes. His labours in that field covered a period of no less than half a century. His first public delivery on the subject dates from 1860, and he dealt with it with undiminished vigour in a course of lectures delivered before the Royal College of Physicians of London in 1908. Thus, even in old age he showed that the keenness of his interest in the subject which he had made his own suffered no abatement; he was ready at all times to defend his views, which, if not always in accord with the trend of contemporary opinion, were based upon his own experimental researches and clinical observation.

It was his work with Claude Bernard which first awakened his interest in such problems, and on his return to London his labours were directed to the extension of his teachers' observations to the domain of pathology. However, as his researches went on he was soon led to dissent from Bernard's views, and in the first edition of his book on diabetes, published in 1862, he expresses his inability to accept the glycogenic theory of carbohydrate metabolism as clearly as in his most recent lectures. He showed that during life the blood in the cavities of the right heart is not richer in sugar than that in other parts of the circulation, and so removed the basis of the theory, then prevalent, that the combustion of sugar is effected in the lungs.

In opposition of the view that sugar is liberated from the store of glycogen in the liver to meet the needs of the tissues he maintained that the small molecules of glucose, if present in a free state in the blood, are of necessity excreted by the kidneys, and that it is erroneous to suppose that only when a certain sugar content of the blood is exceeded does glycosuria ensue. He further maintained that in diabetes the fault lies in a malassimilation of sugar, a failure to incorporate it into larger molecules probably of protein nature, with the result that free glucose enters the circulation, and, as a necessary result, is excreted in the urine. These opinions led to the devotion of much time and labour to the demonstration of the trace of glucose in normal urine and of the carbohydrate fraction in proteins.

Pavy's influence upon the treatment of diabetes is difficult to estimate. There can be no question that during his lifetime great advances were made in the feeding of diabetic patients and in the provision of more satisfactory and less unpalatable bread substitutes for their use. It is certain, too, that he exerted a powerful influence in furthering this progress, as, for example, by the introduction of almond bread. Questions of diet interested him greatly, and apart from his well-known book on food and dietetics, no one has laid greater stress upon the importance of suitable limitations in the treatment of diabetes. In this disease he leaned to the side of strictness in elimination of carbohydrates from the food, holding that no good can result from allowing to the patient materials which he is unable to assimilate rightly. He was a strong upholder of the value of opium and its alkaloids in the treatment of the disease or group of diseases in question, and to him we owe the introduction of codeia as a substitute for opium in the treatment of diabetes. No future writers or workers on diabetes can omit to take Pavy's work into account, and his labours will always be respected, even by those who find themselves least able to accept his views. He has left to those who come after him the example of a long and active life devoted from youth to an honoured old age to the pursuit of scientific work in medicine, work which neither the claims of duty well performed in a large hospital and medical school, nor the strain of a large private practice, ever succeeded in suspending. Fifty years spent in the investigation of a disease, in the laboratory, in the wards, and in the consulting-room, confers an authority which none can gainsay.

We are indebted to Dr. Frederick Taylor for the following note upon Pavy as teacher and hospital physician. Dr. Taylor's words show clearly that Pavy's concentrated interest in his own line of work never seduced him from the discharge of his public or wider responsibilities; he maintained the proper balance between the *savant* and the man of affairs. Dr. Taylor writes: "It is well known that the man of much knowledge is not always a competent teacher, but Dr. Pavy as a lecturer on physiology, the subject in which he early made a reputation, was certainly successful. He was clear, precise, and in simple language put the facts lucidly before his audience, without attempting to enter into unnecessary discussions of theories, in which the majority of the students would probably have taken little interest. He lectured for over 20 years, and for all this period, except the last five years, when he was associated with Dr. Pye-Smith, he delivered the lectures during the whole of the winter session. These were the days before the Vivisection Act, and Dr. Pavy was in the habit of illustrating his lectures, to the great advantage, as I believe, of the student, with occasional demonstrations on the living animal—demonstrations which were judiciously selected and conducted with the greatest skill. The neatness with which Dr. Pavy would cut down upon the vagus, or ligature a vessel in the neck, was very striking. The writer has a vivid recollection of one such lecture, more than 40 years ago, in which Dr. Pavy refuted Bernard's dictum as to the sugar contents of the blood in the hepatic vein; and it has always been to him an instance of the superiority of ocular demonstration, whether by experiment, drawing, or diagram, over mere platform utterances. In his clinical teaching Dr. Pavy was simple, direct, even dogmatic, laying before the student the well-known facts of medicine, and not being inclined to spend time in the consideration of theories for which there might be little evidence. With his interest deeply centred, as no doubt it was, in the relations of diabetes, it might have been thought that his wards would have been full of examples of this disease. This, however, was not the case, though he always had some diabetics under treatment. Unfortunately the class of diabetic case which comes into a general hospital is that which is least suited, both in the form of the disease and in the mental attitude of the patient, to scientific research and observation. And I am afraid that his cases were as prone to resent the restriction of their diet and to partake of forbidden fruit, introduced on visiting days, as those of his colleagues. However, as a clinical teacher he dealt with all subjects alike, clearly and sufficiently if not profoundly, and he attracted a good class to his clinical visits up to the time of his retirement at the age of 61—a retirement which was delayed for one year at the request of the governors in consequence of the rapid depletion of the active medical staff by the loss of five physicians and assistant physicians in six years.

"Dr. Pavy was in all he did methodical, punctual, precise, and never in a hurry. He conscientiously attended all committees requisite for the management of the hospital and medical school, took his share in the responsibility for this very necessary work, and rarely pleaded urgent professional engagements as an excuse for absence. At the same time, as is well known, he had a large private practice, especially among the sufferers from the disease to which he had devoted so much labour, and in renal and digestive disorders. He never relinquished his practice, and saw patients at his house within a few days of his death. To the end he was wrapped up in his work and in his laboratory researches, and except in his holidays, when he was fond of travel, he was content with very little diversion in other directions."

Dr. Pavy married in 1855 Julia, daughter of Mr. William Oliver, by whom he had a daughter Florence, who married the Reverend Borradaile Savory, son of Sir William Savory the famous surgeon, and father of the present baronet.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. A. Hubbell, formerly professor of ophthalmology and otology in the University of Buffalo. Dr. F. W. Page, formerly professor of neurology and psychiatry in the University of Vermont, Burlington. Dr. V. Griffon, physician to the Paris hospitals. Dr. Friedrich Ernst, formerly professor in Zürich. Dr. A. Sitzenfrey, *privat docent* of gynæcology in the University of Giessen. Dr. Christian Gerhard Leopold, an eminent obstetrician and gynæcologist of Dresden, at the age of 65, from heart disease. He began his professional career as assistant to Professor Credé in Leipsic, where he was afterwards extraordinary professor. For the last 30 years he has been director of the Royal Clinic for Women in Dresden, from which post he had arranged to retire on Oct. 1st. He published many papers on obstetrical and gynæcological topics, and was one of the editors of the *Archiv für Gynäkologie*.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bonn:* Dr. Walter Kruse of Königsberg has been appointed to the chair of Hygiene in succession to Dr. Finkler, who is retiring.—*Budapest:* Dr. Bencze has been recognised as *privat-docent* of Medicine and Dr. A. Torday as *privat-docent* of the Pathology of the Circulation.—*Christiania:* At the centenary of the University the following have (amongst others) received the honorary degree of Doctor: Professor Rubner of Berlin, and Professor Strümpell and Professor Rabl of Leipsic.—*Groningen:* Dr. T. S. Steenhuis has been recognised as *privat-docent* of Forensic Medicine.—*Jena:* Dr. T. Meyer-Steinegg, *privat-docent* of the history of medicine, has been promoted to an Extraordinary Professorship.—*Kiel:* Dr. A. Bethe of Strasburg has been appointed to the chair of Physiology in succession to Dr. V. Hensen, resigned.—*Modena:* Dr. E. Cavazza has been recognised as *privat-docent* of Internal Pathology.—*Moscow:* Dr. P. Rybakoff has been promoted to the chair of Neurology and Psychiatry.—*Munich:* The title and rank of Extraordinary Professor have been granted to Dr. Siegfried Oberndorfer, *privat-docent* of pathological anatomy; Dr. Alexander Schmincke, *privat-docent* of general pathology and pathological anatomy; Dr. Otto Neubauer, *privat-docent* of medicine; and Dr. Rudolf Grashey, *privat-docent* of surgery. Dr. Alfred Schönwerth, *privat-docent* of surgery, has been appointed Honorary Professor. Dr. Franz Weber has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Philadelphia (University of Pennsylvania):* Dr. J. H. Austin has been appointed Adjunct Professor of Experimental Medicine.—*Prague (German University):* Dr. Josef Jerie has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Rome:* Dr. Amerigo Filia has been recognised as *privat-docent* of Pædiatry.—*Strasburg:* Dr. C. F. Wenckebach of Groningen has been appointed to the chair of Clinical Medicine in succession to Dr. F. Moritz, resigned.—*Tübingen:* Dr. Paul Linser has been appointed to the newly created chair of Dermatology.—*Vienna:* Dr. Richard V. Wiesner has been recognised as *privat-docent* of Pathological Anatomy.—*Warsaw:* Dr. N. K. Nézholoff of Kieff has been appointed to the chair of Gynæcology.—*Würzburg:* Dr. Martin Reichardt, *privat-docent* of Psychiatry, has been granted the title of Extraordinary Professor.

THE BIRMINGHAM OPEN-AIR SCHOOL.—The open-air school which Birmingham owes to the generosity of Mr. and Mrs. Barrow Cadbury has recently come into use. About 100 children are accommodated, and they have been carefully selected by the education committee's medical officer, Dr. G. A. Auden. Most of the children are suffering from anæmia, debility, malnutrition, and tuberculous glands. Only those whose home conditions were such that treatment received at the school was likely to be supplemented and followed up by home care and rigid adherence to medical advice were chosen, and a further condition that parents should contribute 1*s.* per week towards the cost of the meals served at the school has been readily complied with.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The usual monthly meeting of the executive committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on Sept. 15th. There were present Dr. F. de Havilland Hall, in the chair, Mr. H. P. Symonds (Oxford), Dr. H. A. Sansom, Dr. M. G. Biggs, Dr. F. C. Martley, Mr. J. Brindley-James, Dr. J. W. Hunt, Dr. F. J. Allan, Mr. J. F. Colyer, Dr. W. Knowsley Sibley, and Dr. J. B. Ball. The business of the society during the summer has been exceptionally good. The number of new entrants has been greater than in any similar period of the society's operations, and the sum paid out for sickness claims has been well under the amount expected and provided for in the tables of contributions. The success of the business has enabled the committee to grant a further bonus to the sickness members in the shape of a sum payable at death before the age of 65. The amount so payable varies from £12 to £24, according to the length of membership. Prospectuses and all further particulars on application to Mr. F. Addiscott, secretary, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.—The prizes will be distributed to successful students on Tuesday, Oct. 3rd, at 3 P.M., by the senior physician, Dr. Theodore Dyke Acland, in the Governors' Hall of the hospital.

A DEVONSHIRE CENTENARIAN.—Mrs. Gibbons, of Torquay, celebrated the hundredth anniversary of her birthday last week, and received a congratulatory message from the King.

CHARING CROSS HOSPITAL MEDICAL SCHOOL.—The distribution of prizes to students will take place in the out-patients' hall on Monday, Oct. 2nd, at 3.15 P.M., by H.R.H. the Princess Louise, Duchess of Argyll, president of the hospital. The school, in which extensive alterations have been made, will be open for inspection.

LITERARY INTELLIGENCE.—Messrs W. B. Saunders Company will publish shortly another volume of "Collected Papers" by the staff of the Mayo Clinic. This new work embraces the papers prepared for publication during 1910 by Dr. Chas. H. Mayo and Dr. Wm. J. Mayo and their associates at St. Mary's Hospital, Rochester, Minnesota. The text will be illustrated by some 300 original illustrations.

A WINDFALL FOR SCOTTISH MEDICAL INSTITUTIONS.—Under the will of the late Mr. Edward Davis of Cheltenham a magnificent bequest has been made to Scottish charities. Mr. Davis's fortune amounted to nearly £150,000, but only half of this sum will be required in satisfaction of specific legacies. The residue, which it is expected will amount to £75,000, has been left to trustees with instructions to divide it between such general hospitals and infirmaries in Scotland as they shall select.

THE CATHOLIC NURSING INSTITUTE.—We are frequently asked for the address of a nursing institution where patients are received for medical and surgical treatment for a small fee, so that our readers may be glad to have brought to their notice the Catholic Nursing Institute (60, Lambeth-road) where patients of any religious denomination are received for the sum of £1 1*s.* weekly. There are also a few private rooms for which the charge is £2 2*s.* weekly. The nursing is carried out by the Institute of Trained Nurses of Our Lady of Consolation, and patients are treated either by their own medical men or by the medical officers attached to the institution.

THE HEALTH OF BIRMINGHAM.—There was a considerable improvement in the health of Birmingham last week as compared with the previous week, the total death-rate being 16·7 per 1000, as compared with 20·4; and the zymotic death-rate 3·7, against 6·8. The decline in deaths from diarrhœa and enteritis was from 76 to 45. Stringent by-laws against spitting in the public streets and places within the city have been passed by the city council and are now in force, and the chief constable has been authorised to take such steps as he might consider necessary with regard to their publication and advertisement.

DEATH OF MR. WILLIAM WALTER HARRISON.—A promising career was ended on Sept. 17th by the death of Mr. William Walter Harrison, at the age of 35. Studying at Guy's, he took the diplomas of M.R.C.S. Eng. and L.R.C.P. Lond. in 1899, when he was 23 years of age. He practised at Brighton for some time, and while there was house surgeon at the Brighton, Hove, and Preston Dispensary, and was a member of the local Medico-Chirurgical Society. Unfortunately, he did not have the best of health—in fact, he had to give up his practice and went abroad for a time. Returning, he became resident physician at Manor Valley Sanatorium, Peebles, but illness again overtook him, and he died at Nordrach-on-Dee, Banchory, N.B. He was buried at Keymer, Sussex, by the side of his father and mother.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ANKLESARIA, H. N., F.R.C.S. Edin., has been appointed an Examiner in Surgery to the University of Bombay.

CAMPBELL, DONALD, M.D., C.M. Glasg., has been appointed Medical Officer of Health for the Calne (Wilts) Urban District.

DOBSON, J. R. B., M.R.C.S., L.R.C.P. Lond., has been appointed House Physician at the Royal Hospital for Diseases of the Chest, City-road, E.C.

KENNEDY, ROBERT, M.D., M.S. Glasg., has been appointed to the St. Mungo Chair of Surgery in the University of Glasgow.

KERR, J. M. MUNRO, M.D. Glasg., has been appointed to the Muirhead Chair of Obstetrics and Gynæcology in the University of Glasgow.

LEVIN, JOSEPH J., M.B., Ch.B. Edin., has been appointed Obstetric Assistant at the Ladies' Charity and Lying-in Hospital, Liverpool.

MCCULLOCH, J., M.R.C.S. Eng., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Bexhill-on-Sea District of the county of Sussex.

MORRIS, R. OWEN, M.D. Edin., D.P.H., has been appointed Lecturer to the Welsh National Memorial inaugurated for the Treatment of Tuberculosis.

WALTERS, ENID, M.B. Lond., has been appointed Fourth Assistant Medical Officer and Pathologist at the Devon County Asylum.

WILSON, S. RAWSON, M.B., B.S. Lond., F.R.C.S. Edin., has been appointed Anæsthetist to the Salford Royal Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRKENHEAD BOROUGH HOSPITAL.—Senior Resident House Surgeon. Salary £100 per annum.

BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN.—Resident Medical Officer and Resident Surgical Officer for six months. Salary in each case £80 per annum, with board, washing, and attendance.

BIRMINGHAM, CITY EDUCATION COMMITTEE.—Medical Officer for Inspection of School Children. Salary £250 per annum.

BIRMINGHAM CITY FEVER HOSPITAL, Little Bromwich.—Medical Superintendent. Salary £250 per annum, with board and residence.

BIRMINGHAM, UNIVERSITY OF.—Lecturer in Physiological Department. Salary £150 per annum.

BODMIN, CORNWALL COUNTY ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £140 per annum, with rooms, rations, laundry, and attendance.

BOLINGBROKE HOSPITAL, Wandsworth Common, S.W.—Two House Surgeons for six months. Salary at rate of £75 per annum, with board and residence.

BRADFORD ROYAL INFIRMARY.—House Physician, unmarried, for six months. Salary at rate of £100 per annum, with board, residence, and washing.

BRISTOL ROYAL INFIRMARY.—House Surgeon. Salary £100 per annum, with apartments, board, and laundry.

BURSLEM, HAYWOOD HOSPITAL.—Resident Medical Officer (female). Salary £100 per annum, with board, residence, and laundry.

BURY INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, residence, and laundry.

CAMBERWELL PROVIDENT DISPENSARY.—Two vacancies on Medical Staff.

CAMBRIDGE, ADDENBROOKE'S HOSPITAL.—Second House Surgeon. Salary £80 per annum, with board, residence, and laundry.

CARLISLE DISPENSARY.—Resident Medical Officer. Salary £150 per annum, with apartments.

CARSHALTON, QUEEN MARY'S HOSPITAL FOR CHILDREN.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing.

CHARTHAM, NEAR CANTERBURY, KENT COUNTY ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £192 per annum, with quarters, washing, &c.

CHESTER, CITY OF.—Assistant Medical Officer of Health. Salary £250 per annum.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—House Physician. Salary £80 per annum, with board, apartments, and laundry.

CROOKSBURY SANATORIUM, Farnham, Surrey.—Resident Medical Officer.

COLCHESTER, ESSEX COUNTY HOSPITAL.—House Surgeon. Salary £80 per annum, with board, washing, and residence.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Two Junior House Surgeons. Salary £80 per annum, with rooms, board, washing, and attendance.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Assistant House Surgeon, unmarried, for six months. Salary at rate of £75 per annum, with board, apartments, laundry, &c. Also House Surgeon, unmarried Salary £125 per annum, with apartments, board, laundry, &c.

DOWNPATRICK, DOWN DISTRICT LUNATIC ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £130 per annum, with apartments, board, washing, &c.

DREADNOUGHT HOSPITAL, Greenwich.—Two House Physicians and Two House Surgeons, all for six months. Salary in each case £50 per annum, with board, residence, and washing. Also Honorary Anæsthetist.

DUDLEY, GUEST HOSPITAL.—Assistant House Surgeon for six months. Salary £75 per annum, with residence, board, and washing.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Second Medical Officer for six months. Salary at rate of £40 per annum, with luncheon and tea provided.

EAST SUFFOLK COUNTY EDUCATION COMMITTEE.—Assistant School Medical Officer. Salary £250 per annum.

ENNISKILLEN, FERMANAGH COUNTY HOSPITAL.—House Surgeon. Salary £72 per annum.

EXETER, ROYAL DEVON AND EXETER HOSPITAL.—House Physician and Assistant House Surgeon for six months. Salary at rate of £60 per annum, with board, apartments, and washing.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.—Medical Officer. Salary 25 guineas per annum.

HASTINGS, EAST SUSSEX HOSPITAL.—Assistant House Surgeon. Salary at rate of £60 per annum, with residence, board, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Assistant Casualty Medical Officer, unmarried, for six months. Salary £30, with board, residence, &c.

HULL ROYAL INFIRMARY.—Two Casualty House Surgeons. Salary at rate of £80 per annum, with board and lodging.

LEEDS GENERAL INFIRMARY.—Resident Medical Officer. Salary £120 per annum, with board, residence, and washing.

LINCOLN COUNTY HOSPITAL.—Junior House Surgeon, unmarried, for six months. Salary at rate of £75 per annum, with board, residence, and washing.

LINCOLN GENERAL DISPENSARY.—Resident Medical Officer, unmarried. Salary £300 per annum, with apartments, &c.

LIVERPOOL EYE AND EAR INFIRMARY, Myrtle-street.—Honorary Assistant Surgeon.

LIVERPOOL WORKHOUSE HOSPITAL, Brownlow Hill.—Two Resident Assistant Medical Officers. Salaries £120 and £100 per annum respectively, with apartments, &c.

LOWESTOFT HOSPITAL.—House Surgeon, unmarried. Salary at rate of £100 per annum, with board, residence, and laundry.

MELROSE, ROXBURGH DISTRICT ASYLUM.—Assistant Medical Officer Salary £160 per annum, with board, lodging, and washing.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—House Physician House Surgeon, Assistant House Physician, and Assistant House Surgeon for six months. Salary of House Physician and House Surgeon at rate of £60 per annum, with board and washing. Salary of Assistant House Physician and Assistant House Surgeon at rate of £40 per annum, with board and washing. Also Ophthalmic Surgeon.

MILLER GENERAL HOSPITAL FOR SOUTH-EAST LONDON, Greenwich-road, S.E.—Junior House Surgeon for six months. Salary at rate of £80 per annum, with board, attendance, and laundry.

NEWCASTLE THROAT, NOSE, AND EAR HOSPITAL.—Two Honorary Assistant Surgeons.

NEWCASTLE-UPON-TYNE, ROYAL VICTORIA INFIRMARY.—Three House Physicians, Four House Surgeons, One Accident Room House Surgeon, One House Surgeon to the Aural and Ophthalmic Departments, One House Surgeon to the Skin and Gynæcological Departments, and One House Surgeon to Out-patients.

NEWPORT AND MONMOUTHSHIRE HOSPITAL.—House Surgeon. Salary £60 per annum, with board, residence, and laundry.

NOTTINGHAM GENERAL HOSPITAL.—Assistant House Physician. Salary £100 per annum, with board, lodging, and washing.

NOTTINGHAM WORKHOUSE INFIRMARY.—Resident Assistant Medical Officer, unmarried. Salary £150 per annum, with apartments, board, washing, and attendance.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—House Physician and House Surgeon for six months. Salary in each case at rate of £52 10s. per annum, with board and residence.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—Assistant Surgeon.

PORTSMOUTH, ROYAL PORTSMOUTH HOSPITAL.—House Physician for six months. Salary £75 per annum, with board, &c.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Resident Medical Officer for four months. Salary at rate of £50 per annum, with board, residence, and washing.

REDHILL, EARLSWOOD ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, with board, residence, and washing.

ROYAL EAR HOSPITAL, Soho.—House Surgeon. Salary £40 per annum. Also Assistant Surgeon.

ROYAL EYE HOSPITAL, Southwark, S.E.—House Surgeon for six months Salary 50 guineas per annum, with board and residence.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—House Physician and House Surgeon for six months. Board, lodging, and washing provided. Also House Physician and House Surgeon (females) Board, lodging, and washing provided.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, London, E.C.—Clinical Assistant. Also Resident Medical Officer for six months. Salary at rate of £120 per annum, with board, lodging, and washing.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—Resident House Surgeon, unmarried, for six months. Salary £100 per annum, with board, residence, and washing.

ROYAL NAVAL MEDICAL SERVICE.—Fifteen Commissions.

ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Honorary Gynæcologist.

SALFORD ROYAL HOSPITAL.—Casualty House Surgeon for six months. Salary at rate of £50 per annum, with board and residence.

SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone-road, N.W.—Resident House Surgeon. Salary £80 per annum, with board and residence.

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—House Physician. Salary £100 per annum, with rooms, board, and washing.

SOUTHWARK UNION INFIRMARY, East Dulwich Grove, S.E.—Assistant Medical Officer. Salary £120 per annum, with board, lodging, and washing.

STOCKPORT INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, washing, and residence.

TAUNTON AND SOMERSET HOSPITAL.—Resident Assistant House Surgeon for six months. Salary at rate of £70 per annum, with board, lodging, and laundry.

THROAT HOSPITAL Golden-square, W.—Resident House Surgeon Salary £75 per annum, with board, residence, and laundry. Also Honorary Assistant Registrar.

WALSALL AND DISTRICT HOSPITAL.—House Physician and Casualty Officer. Salary £80 per annum, with board, residence, and laundry.

WESTMINSTER HOSPITAL.—Assistant House Physician for three months. Board provided.

WESTON-SUPER-MARE HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Caldicot, in the county of Monmouth; at Cardiff, in the county of Glamorgan; and at Portumna, in the county of Galway.

Births, Marriages, and Deaths.

BIRTHS.

BAGSHAWE.—On Sept. 21st, at the Manor House, Rickmansworth, to Dr. and Mrs. Arthur G. Bagshawe—a son.

VERNON.—On Sept. 21st, at Norham-road, Oxford, the wife of H. M. Vernon, M.D., of a daughter.

MARRIAGES.

COLLINS—HATCHARD SMITH.—On Sept. 20th, at Christ Church, Epsom, Michael Abdy Collins, B.S., M.D. Lond., to Sybil, youngest daughter of J. Hatchard Smith, F.R.I.B.A.

ILIEWICZ—HELE.—On Sept. 21st, at Holy Trinity, Balham, S.W., Fleet-Surgeon Henry F. Iliewicz, M.B., R.N., of H.M.S. *Indomitable*, to Bessie E. Hele, daughter of the late G. F. Hele, of Stoke Devonport, and of Mrs. Hele, of St. Ives, Hunts.

MUSGROVE—PETTIGREW.—On Sept. 20th, at All Souls, London, James Musgrove, M.D., F.R.C.S., to Elsie Bell Pettigrew, second daughter of the late Sir William Gray.

DEATHS.

ANDREW.—On Sept. 19th, at Atholl-crescent, Edinburgh, James Andrew, M.D., F.R.C.P.E.

CONOLLY.—On Sept. 19th, at Bassett-road, North Kensington, W., Stephen Fullom Conolly, M.R.C.S., L.R.C.P., in his 62nd year.

PAVY.—On Sept. 19th, at Grosvenor-street, W., Frederick William Pavy, M.D., F.R.S., LL.D., in his 83rd year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

BOOKS, ETC., RECEIVED.

CROSBY LOCKWOOD AND SON, London.

The Sewerage of Sea Coast Towns. By Henry C. Adams, Assoc.M. Inst.C.E., M.I.Mech.E., A.M.I.E.E., M.R.San.I. Price 5*s.* net.

GOLDSCHMIDT, J., Heiligegeiststrasse, 52. Berlin, C.2.

Hand- und Lehrbuch meiner Reflexmassage für den Praktischen Arzt. Ein neuer, praktischer Weg zur Diagnose, Therapie und Prophylaxe der Krankheiten. Von Dr. B. Barczewski, Stabsarzt d.L. Berlin-Schöneberg. Price M.3.50.

HARPER AND BROTHERS, London and New York.

Chemical Phenomena in Life. By Frederick Czapek, M.D., Ph.D., Professor of Plant Physiology in the University of Prague. Price, cloth, 2*s.* 6*d.* net.

The Ancient Egyptians and Their Influence upon the Civilisation of Europe. By G. Elliot Smith, M.A., M.D., F.R.S., Professor of Anatomy in the University of Manchester. Price, cloth, 2*s.* 6*d.* net.

KEGAN PAUL, TRENCH, TRÜBNER, AND CO., LIMITED, London.

The Hunterian Lectures on Colour-Vision and Colour-Blindness. Delivered before the Royal College of Surgeons of England on Feb. 1st and 3rd, 1911. By Professor F. W. Edridge-Green, M.D. Durh., F.R.C.S. Eng., Belt Medical Research Fellow. Price 3*s.* 6*d.* net.

MACMILLAN AND CO., LIMITED, London.

A Practical Handbook of the Diseases of the Ear. For Senior Students and Practitioners. By William Milligan, M.D., Aurist and Laryngologist to the Royal Infirmary, Manchester, Surgeon to the Manchester Ear Hospital; and Wyatt Wingrave, M.D., Pathologist (lately Physician) to the Central Throat and Ear Hospital, London, and to the Polyclinic, London. Price 15*s.* net.

UNIVERSITY OF BRISTOL, Registrar of, Bristol.

University of Bristol. Calendar, 1911-12. Price not stated.

UNIVERSITY PRESS, Cambridge.

A Text-book of Experimental Psychology, with Laboratory Exercises. By Charles S. Myers, M.A., M.D., Sc.D., of Gonville and Caius College, University Lecturer in Experimental Psychology, Cambridge. Second edition. Part I. Text-book. Part II. Laboratory Exercises. Price 10*s.* 6*d.* net.

WILEY, JOHN, AND SONS, New York. CHAPMAN AND HALL, LIMITED, London.

Immune Sera. A Concise Exposition of the Main Facts and Theories of Infection and Immunity. By Dr. Charles Frederick Bolduan, Bacteriologist, Research Laboratory, Department of Health, City of New York. Fourth edition, rewritten and enlarged. First thousand. Price, cloth, $1.50.

Manual of Psychiatry. By J. Rogues de Fursac, M.D., formerly Chief of Clinic at the Medical Faculty of Paris, Physician in Chief of the Public Insane Asylums of the Seine Department. Translated and edited by A. J. Rosanoff, M.D., Second Assistant Physician, Kings Park State Hospital, N.Y. Third American from the Third French Edition. Revised and enlarged. Price $2.50 net.

Notes, Short Comments, and Answers to Correspondents.

HEALTH AND SANITATION IN MALTA.

A REPORT on the Malta Blue-book for the year 1910-11, prepared by the Hon. E. P. S. Roupell, D.S.O., has just been issued from the Colonial Office. According to a census taken on April 2nd, 1911, the civil population of the islands numbered 211,473. The birth-rate was 36·12 per 1000, as compared with 36·07 in the previous year, whilst the average birth-rate for the last 12 years was 38·26 per 1000. The death-rate of the civil population was 21·42 per 1000, as against 22·57 in 1909-10. The general state of health was satisfactory, and the colony was not visited by any epidemic. There were 43 cases of small-pox (with four deaths), all imported. The incidence of enteric fever was normal, and the cases were not confined to any particular town or village. Mediterranean fever has shown a considerable decrease among the civil population and has practically ceased altogether in the fleet and garrison. The number of vaccinations performed by district medical officers in Malta and Gozo was 6565, of which 6451 were successful. The death-rate amongst children under 12 months was 236·93 por 1000 births, as against 242·46 in the preceding year. There was also a slight decrease in the death-rate of children under five years. During the year several works under the general drainage scheme were carried out. The total number of persons admitted into the hospitals and maintained in the other charitable institutions of Malta and Gozo was 8182, as against 7309 in 1909-10. In addition to these, 119,893 persons were attended by the district medical officers at the Government dispensaries or at their own homes.

The mean temperature for the summer months was 73·9°, and for the winter months 53·7°. The highest temperature in the shade was 92·7° on July 20th, 1910, and the lowest 39·7° on Feb. 10th, 1911. The total rainfall was 18·976 inches, or 5·367 less than that of the previous year. The average rainfall for the last ten years was 22·260 inches.

HOW TO SPREAD INFECTION.

A MAN described as a working tailor, and living in [St. James's, S.W., was summoned at the Marlborough-street police-court recently for taking his son, whom he knew to be suffering from scarlet fever, in a public vehicle from St. James's to Bethnal Green. The medical man whom he had consulted gave evidence that he had told the defendant what was the matter with the boy, and Dr. F. J. Allan, medical officer of health to the City of Westminster, informed the magistrate that the defendant had said to him that he took his son in a taxi-cab to the East-end to the house of a relative because he did not believe in the medical practitioners of the West-end, preferring those of the East-end. Mr. Mead endeavoured to impress upon the defendant the cruelty of his conduct in recklessly exposing to infection a number of persons who might use the same taxi-cab afterwards, but taking into consideration his apparently humble position inflicted a fine of 15*s.*

A CLOSED CONGRESS.

A RECENT message from Reuter's Moscow correspondent, which appeared as a small paragraph in some English newspapers, must have given rather a shock to medical men in this country, who are unaccustomed to the idea of police interference in scientific discussions, and do not naturally associate neurological congresses with politics. The paragraph ran as follows: "Moscow, Sept. 17th. The Congress of Specialists in Nervous and Mental Diseases which was opened here to-day was closed by the police official in attendance owing to the sharp criticism of the Government contained in a speech made by Professor Sertsky."

ENDOLYTIC TUBES FOR CLINICAL DIAGNOSIS.

THE capillary tube and its well-known peculiar force supply an ingenious and delicate means of clinically testing urine for albumin or sugar. The endolytic tube represents a tiny test-tube in which a negative or positive result can be equally well observed. The capillary tube is charged with the sensitive and trustworthy agent, salicyl-sulphuric acid, for albumin; a column about half an inch long is left at the end of the tube, both ends being open. The capillary attraction is capable of drawing up a longer column than this, and so when the tube is dipped into the urine to be tested a column of urine of about equal length pushes the column of reagent forward. In a moment they mingle, and in the presence of albumin an unmistakeable turbidity appears, its density depending upon the quantity of albumin present. Similarly, capillary tubes are charged with Fehling's solution, and when some boiling water is poured over the tube, after some urine has been drawn up by capillarity, the reduction to red cuprous oxide is readily observed when sugar is present. The endolytic tubes are supplied sealed with a definite quantity of reagent in them. They are generally overcharged, so as to allow of the adjustment of a column of reagent at

the end of the tube sufficient for the reaction, and the fluid should be short of the full capillary attraction of the tube, so that when the endolytic tube is dipped into the urine a column of about equal length enters for the test. We have tried the use of the tubes with solutions of sugar and albumin, and the results were very plainly revealed. They should be very useful for clinical purposes, especially as they contain reliably prepared reagents which are kept sealed against any disturbing influences; they need not be opened until immediately prior to making a test. Specimens were submitted to us by the Endolytic Tube Co., Hampton-on-Thames.

Tropics will be grateful to readers of THE LANCET who can recommend him any book or books on the subject of tropical and sub-tropical diseases. "Is there any book or books," he asks, "not too extensive where one could get a short description of the diagnosis and treatment of such diseases, suitable for a man who has been appointed medical officer to a rubber estate in the Malay States?"

Medicus would like to hear from any reader of THE LANCET who may have observed attacks of asthma following the administration of ordinary doses of aspirin.

Scot.—It would be quite incorrect to style him "Dr.," and if he intends to finish his curriculum such action might be prejudicial to his future.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for October, 1911:—

April October.—Rome Exhibition (United Italy's Jubilee).
,, 29th-Oct. 26th (Turin).—International Exhibition.
May 3rd-Oct. 31st (Glasgow).—Scottish Exhibition.
,, 6th-Oct. 31st (Dresden).—International Hygiene Exhibition (British Section opens June 14th).
May 12th-Oct. 31st (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
May 18th-October 31st (London, Shepherd's Bush).—Coronation Exhibition.
Sept. 19th-Oct. 31st (London).—Earl's Court Exhibition.
,, 23rd-Oct. 21st (London, Olympia).—Electrical Exhibition.
,, 24th-30th (Karlsruhe).—Eighty-third Meeting of German Physicists and Physicians.
,, 26th-30th (Brussels).—Third Congress of the International Society of Surgery and Exhibition of Fractures.
,, 28th-30th (Dresden).—International Congress for the Protection of Mothers and Sexual Reform.
,, 30th (Bruges).—Sixth Belgian Congress of Neurology and Psychiatry.
September-November (Antwerp).—International Exhibition of Alimentation, Brewing, Wines, and Liqueurs.
Oct. 1st-4th (Liége).—Second Congress of Alimentation.
,, 2nd-4th (Frankfurt-a-Main).—Fifth Annual Meeting of the Society of German Neurologists.
,, 2nd-5th (Turin).—International Congress of Pathology.
,, 2nd-6th (London, Royal Horticultural Hall).—Seventh London Medical Exhibition.
,, 2nd-7th (Dresden).—Third International Housing Congress.
,, 2nd-7th (Paris).—French Congress of Surgery, Twenty-fourth Annual Congress.
,, 3rd-5th (Turin).—Ninth National Congress of Medici Condotti.
,, 3rd-6th (London).—Dairy Show.
,, 5th-7th (Paris).—Fifteenth Meeting of the French Association of Urology.
,, 6th and 7th (Paris).—French Association of Pediatrics.
,, 9th-12th (Turin).—Twenty-first Congress, Italian Society of Internal Medicine.
,, 9th-13th (Cologne).—Seventh International Congress of Criminal Anthropology.
,, 10th (Paris).—International Sanitary Conference (to Revise the International Sanitary Convention of 1903).
,, 12th-18th (Rome).—Fifth Annual Meeting of the Italian Society for the Advancement of Science.
,, 13th-16th (Turin).—Third National Congress of Professional Diseases.
,, 15th (The Hague).—International Opium Conference.
,, 20th-22nd (Roubaix).—Second National Congress of the Mutalité Maternelle.
,, 22nd and 23rd (Lyons).—Twelfth French Congress of Medicine.
,, 25th-27th (New York City).—Annual Conference of Sanitary Officers of the State of New York.

EDITORIADTICES.

IT is most important that cunications relating to the Editorial business of THE ET should be addressed *exclusively* "TO THE EDITOR,1 not in any case to any gentleman who may be suppco be connected with the Editorial staff. It is urgently ssary that attention should be given to this notice.

It is especially requested that i intelligence of local events having a medical interest, oich it is desirable to bring under the notice of the prion, may be sent direct to this office.

Lectures, original articles, anaports should be written on one side of the paper onlND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTTHAT THE NAME OF THE AUTHOR, AND IF POSSIBLF THE ARTICLE, SHOULD BE WRITTEN ON THE BLO TO FACILITATE IDENTIFICATION.

Letters, whether intended for insion or for private information, must be authentroated the names and addresses of their writers—not necessarily publication.

We cannot prescribe or recommenractitioners.

Local papers containing reports news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publion, sale and advertising departments of THE LANCETould be addressed *"To the Manager."*

We cannot undertake to return MS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1911, which was completed with the issue of June 24th, were given in THE LANCET of July 1st.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1911 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.
